6. The minimum amount of urine necessary for duplicate analyses and still have sufficient sample for referee analysis by the defendant is 3.0 mL.

7. SUMMARY
   a. HAVE SUBJECT VOID. NOTE TIME.
   b. THEN, AFTER 20 MINUTES, TAKE SAMPLE FOR ANALYSIS. NOTE TIME.
   c. SECURE CAP TIGHTLY AND LABEL BOTTLE AND ENVELOPE WITH "FOR ALCOHOL ANALYSIS".

8. EXCEPTION:
   a. URINE AS A SAMPLE FOR DRUG ANALYSIS
   b. For all drug analysis purposes (except alcohol), the best sample to be collected is the first void. A separate "Urine Sample for Alcohol/Drug Analysis" kit should be used to collect a sample for drug analysis. Collect a full bottle if possible.

9. Any sample that is received not in compliance with these prescribed collecting and handling procedures shall be analyzed and the deficiency described in laboratory records.

D. Procedures for Obtaining Blood Samples from Post Mortem Sources

1. A blood sample is obtained prior to the start of any embalming procedure. Blood samples are not collected from the circulatory system effluent during the arterial injection of embalming fluid. Care is taken to avoid contamination by alcohol from the gastro-intestinal tract, directly or by diffusion there from. The sample is taken from a major vein or the heart. Tubes for collecting blood contain an anticoagulant (potassium oxalate) and a preservative (sodium fluoride). Only containers for which Non-Interference data sheets have been completed will be used. To insure that coroner's office is kept aware of the proper procedures for collecting and handling samples from post mortem sources for Forensic Alcohol Analysis, a copy of this procedure is available upon request.

2. Any sample that is received not in compliance with these prescribed collecting and handling procedures shall be analyzed and the deficiency described in laboratory records.

E. Maintenance of identity and integrity of the sample, required by Section 1219 of Title 17 of the California Code of Regulations, shall include the following procedures:

1. Label for Tube or Vial: The label of the blood vial or tube shall contain at least the following information:
   a. Full name of subject
   b. Date blood drawn
   c. Initials of person drawing blood
   d. Initials of witnessing officer
2. Envelope or Other Container Used for Enclosing and Identifying Blood Sample Tube or Vial: The blood sample envelope or other container label shall include at least the following information:
   a. Full name of subject
   b. Submitting agency
   c. Geographical location where blood sample was drawn, i.e., name and/or address of hospital, jail or other facility
   d. Name of person drawing blood sample
   e. Date blood sample drawn
   f. Time blood sample drawn
   g. Signature of witnessing officer
   h. A form for establishing the chain of possession, such as:
      
      i. CHAIN OF POSSESSION: (To be filled in by each person having possession of sample)

      | Received From | Received By | Date |
      |---------------|-------------|-----|
      |               |             |     |
      |               |             |     |
      |               |             |     |

3. Blood and urine samples must be collected in the kits provided by the Forensic Services Division. See Below for example. The vials and jars in these kits contain preservative, which is necessary to prevent the production or breakdown of alcohol by bacteria. If all significant factors have not been considered, samples collected in other containers may not give reliable analytical results.

4. Blood and Urine kits may be obtained from the Drugs Alcohol and Toxicology Section during normal working hours (Mon.-Fri., 8:00-12:00 and 1:00-5:00). Kits are also kept in the alcohol testing room of the Martinez Detention Facility for use at that location.

5. Any blood samples that are received not in compliance with these prescribed collection, withdrawal, handling, and preservation procedures shall be analyzed, but the deficiency shall be described in laboratory records.

F. Blood Withdrawal-General Information

1. As a convenience to our client agencies, the Forensic Services Division has arranged for blood withdrawal in Contra Costa County. Since 1998, the Sheriff's Department, in cooperation with the Contra Costa County Health Services Department, arranged for blood withdrawal for HIV testing in Contra Costa County.

2. The Forensic Services Division contracts with a private group of phlebotomists (blood technicians) to provide blood withdrawal for law enforcement. The draws may be requested at police agencies, hospitals and any other location in Contra Costa County. This group has phlebotomists on-call around the clock. Their services are used most frequently in the following instances:
   a. To draw blood at the Martinez Detention Facility
   b. To draw blood at hospitals,
   c. To draw blood at police agencies with holding cells and who do not transport drinking drivers immediately to the Martinez Detention Facility, and
   d. On felony drunk driving and other felony criminal cases.
   e. HIV testing in criminal cases.

3. The contract blood technicians consider cooperation to be tacit consent. The contract blood technicians will participate in forced blood withdrawals when deemed necessary by the police agency. The forced draw is also performed in compliance with a court order specifically directing that the sample shall be taken with force when necessary.

4. The cost of blood withdrawal is borne by the agency requesting the sample. The contract company bills the Forensic Services Division for all blood withdrawals. The charge to the Division is passed on to the requesting agency in quarterly bills.

G. Procedures for Blood Withdrawal within Contra Costa County
1. Obtaining a Blood Withdrawal from a Contract Blood Technician
   a. Call Central Medical Laboratories (CML) dispatch at (800) 288-4441 any time 24 hours a day, and ask for the contract blood withdrawal on-call blood technician.
   b. Give the dispatcher your name, location, and name of the subject.
   c. If circumstances arise whereby the contract blood technician is no longer needed, call dispatch and notify them immediately. Agencies will have to pay for a call-out, even if no sample is drawn, if the blood technician is in transit.

2. Blood Withdrawal Procedures for Alcohol/Drug Testing
   a. Use a blood withdrawal kit distributed by the Forensic Services Division only. They can be found in the Alcohol Testing Room of the MDF and are carried by the contract blood technicians.
   b. The requesting officer completes the information on the front of the kit envelope, in full.
   c. On driving offenses, the blood withdrawal may be performed only by a licensed doctor, nurse, medical technologist, biotechnologist, paramedic or phlebotomist. Any qualified medical personnel may perform blood withdrawal in other types of cases.
   d. Using the contents of the kit, the person withdraws the blood according to the directions on the back of the envelope. If the sample is to be analyzed for drugs, two additional vials of blood are desirable using the same type of grey top vials. The extra supplies are carried by the blood technicians.
   e. The blood withdrawal must be witnessed by an officer. He/she must watch carefully enough so that he/she can testify in court regarding the procedures used. The person performing the blood withdrawal may refuse to perform the withdrawal if it is not witnessed.
   f. The person drawing the blood completes the information required on the labels for the vials, attaches them to the vial, and gives the vials to the requesting officer.
   g. The person drawing the blood completes the Declaration form enclosed in the kit.
   h. The person drawing the blood retains his/her copy of the Declaration, and gives the other copies to the requesting officer.
   i. The requesting officer places the seals over the tops of the vials and initials them and the vial labels.
   j. The copy of the Declaration for the District Attorney's Office is submitted by the requesting officer with the filing paperwork.
   k. The requesting officer places the seal over the envelope flap and initials it.
   l. The kit is submitted to the Drugs Alcohol and Toxicology Section, Monday through Friday between 8:00 a.m. and 5:00 p.m. or is placed in the refrigerated drop box in the Alcohol Testing Room at the MDF or at Property and Evidence Services if access is authorized to that facility.

   a. Use blood tubes distributed by the County Health Services Department. These tubes are available from the Health Services Department and the on-call blood withdrawal contract blood technicians.
   b. The person drawing the blood uses the appropriate blood tube for HIV testing and standard medical practices for cleansing the withdrawal site.
   c. If the withdrawal is for evidentiary purposes, then the withdrawal should be witnessed by an officer so that he/she may testify in court regarding the procedures used.
   d. The blood tube should not be submitted to the Forensic Services Division. The tubes should be submitted to the County Public Health Laboratory at the Contra Costa County Regional Medical Center in Martinez for Contra Costa County cases or placed in the refrigerator marked for Health services at the MDF Breath Testing Room.

H. How to Submit a Request for Examination
   1. Completing the information required on the front of one of these kits and submitting it to the Drug Alcohol and Toxicology Section of the Forensic Services Division is a sufficient request for analysis in most cases. The Coroners cases not submitted in one of the above listed kits must have a "Coroners Office Toxicology Request Form" attached. The information requested on the envelope must be completed in full.
   2. Unless otherwise marked on the kit, a Blood Sample for Alcohol/Drug Analysis kit will be tested for alcohol and drugs unless the prior investigation warrants only an alcohol analysis be performed. If only alcohol analysis is
needed, this should be clearly noted in the check box near the top of the envelope by the requesting person or by the submission of a general examination request form.

3. Kits requesting analysis for both alcohol and drugs in a case of driving under the influence will be examined for alcohol first. Drug analysis will also be performed, if requested, in this laboratory or forwarded to another laboratory for testing based on the alcohol level and the arrangements made by the client agency unless special arrangements are made with the agency
   a. Richmond Police Department and Pittsburg Police Department have requested special handling for alcohol/toxicology cases. See the most recent communications from these or other agencies for more information.

I. Submitting Ante-Mortem Blood and Urine Cases
   1. Blood and urine samples may be submitted to the Drug Alcohol and Toxicology Section Monday through Friday between 8:00 a.m. and 5:00 p.m. or placed in the drop box inside the refrigerator of the Alcohol Testing Room at the Main Detention Facility in Martinez 24 hours a day. Samples should be submitted as soon as possible after collection to avoid degradation of the drugs or alcohol. If a timely submission is not possible, blood and urine samples should be refrigerated, not frozen, until they can be submitted.

J. Submitting Coroners Cases
   1. Blood, urine and vitreous can be submitted in Coroner Kits. A request form must be attached for toxicology analysis.
   2. The blood alcohol equivalent on a postmortem urine sample will be reported using a conversion factor that is applicable when subjects have emptied their bladder recently. This factor may not be applicable if the urine was pooling in the bladder over a prolonged period prior to death.
   3. The lab will not be able to give a blood alcohol equivalent for cavity fluids submitted. The sample type will be reported and the alcohol content will be reported.
   4. Gastric and tissue samples will be forwarded to an outside laboratory under a Toxicology Request for analysis.
   5. Decomposed samples may be forwarded to an outside laboratory under a Toxicology Request for analysis.
   6. The vitreous alcohol concentration will be reported as a blood alcohol concentration or BAC.

K. Kits
   1. Kits are provided by the Forensic Services Division for the submission of blood, urine and vitreous samples for alcohol and/or drugs:
      a. Blood Sample for Alcohol/Drug Analysis
         i. Each vacuum vial for blood collection has an expiration date, after which the vacuum in the vial cannot be guaranteed.
      b. Urine Sample for Alcohol/Drug Analysis
         i. For alcohol analysis the kit is intended to collect a second urine sample 20 minutes after first emptying of the bladder. Failure to do so can affect the reliability of test results.
         ii. Urine collection kits do not have an expiration date. They can be used indefinitely.
   2. The containers in each of these kits contain particular anticoagulants and/or preservatives intended to ensure the quality of the sample for analysis and are in compliance with the California Code of Regulations, Title 17. Failure to use the proper anticoagulant or preservative can reduce the reliability of test results.
   3. Other containers and kits from other laboratories are unlikely to contain the required anticoagulant and preservative. Consequently, only kits supplied by the Forensic Services Division should be used to collect urine or blood samples for analysis by this laboratory. Kits are available at no charge from the Division during normal working hours.
   4. Each kit is assigned a unique container number that can be found on the kit envelope and on the label(s) for the container(s). These container numbers are intended to prevent accidental mix-up of samples from different subjects.
   5. All kits are sealed when distributed to ensure that the contents are intact. Any kits, which are not sealed, should be returned to the Forensic Services Division.
   6. Instructions for the use of the kits can be found on the back of each envelope. The instructions are self-explanatory and should be followed carefully to ensure proper collection of the sample and proper handling of the paperwork.
7. Example of Kits-Below
   a. FRONT OF BLOOD SAMPLE FOR ALCOHOL/DRUG ANALYSIS KIT
   b. BACK OF BLOOD SAMPLE FOR ALCOHOL/DRUG ANALYSIS KIT
   c. FRONT OF URINE SAMPLE FOR DRUG ANALYSIS KIT
   d. BACK OF URINE SAMPLE FOR DRUG ANALYSIS KIT
   e. FRONT OF CORONER BLOOD/VITREOUS SAMPLE FOR ALCOHOL/DRUG ANALYSIS KIT
   f. BACK OF CORONER BLOOD/VITREOUS SAMPLE FOR ALCOHOL/DRUG ANALYSIS KIT
I. Policy: The following guidelines for the preparation of examination records must be followed in all cases. Failure to do so will result in the report and examination records being returned to the analyst for correction. These guidelines represent the most common note taking requirements. See the Division Manual policy for more information (FSD.42).

A. The case record is considered files containing administrative and examination documentation generated or received by a laboratory pertaining to a particular case. For more information about Case Records refer to the Division Policy. The case record consists of:

1. The report and notes/examination documentation (case file)
2. Administrative records may be any of the following and will be uniquely identified by the laboratory number.
   a. Communications (phone or e-mail communication)
   b. Drawings (photocopies are acceptable)
   c. Photographs
   d. Declaration of blood withdrawal (see B. 6. g. for details regarding the Declaration)
   e. Coroner's Request Forms
   f. District Attorney's Request Forms
   g. Police report
   h. Discovery requests or referee analysis requests are maintained
3. The electronic chain of custody. The official chain of custody is maintained in the Laboratory Information Management System (LIMS).
   a. The chain of custody at the time the case is submitted for review may be included in the case file.
4. The Lot # of the purchased NTRM standards (NIST-Traceable Reference Material), water-ethanol quality controls, blood matrix quality controls, internal standard, resolution solution and the equipment used for the analysis will be documented in the case notes.
5. The only methods used for quantitative analysis are BAC.MTH, BACa.MTH, and BACb.MTH.
   a. The operating parameters for these methods may be located in the maintenance binder or in the Validation Binders or in the Blood Alcohol Technical Unit Manual.
6. The following analytical sequence "batch" or "run" documents are generated and reviewed for each run.
   a. Analytical Worklist
   b. Sequence Traceability Worksheet
   c. Blood Alcohol Gas Chromatography Worksheet
   d. Alcohol Dispensing Tray Map(if used)
   e. Summary Report
   f. Cal Plots A & B (for calibration of methods: BACa & BACb)
   g. Alcohol Batch Review List
7. Sequence "batch" or "run" documents are entered as requests in LIMS. These "run" requests will follow the normal LIMS signature pattern at each milestone to show review of data. See below for additional information.

8. Communication on Business Record or Official Record for court is maintained electronically under case activities in the Laboratory Information Management System (LIMS).

B. Examination Records

1. Examination records (notes) and observations, data, and calculations shall be recorded at or near the time they are made and shall be identifiable to the specific task.

2. Examination records shall be of a permanent nature in ink or computer generated. See BA.31 for instructions on how to generate electronic notes.

3. The case notes and records shall be sufficiently detailed to include the test conditions and shall include the identity of the personnel responsible for performance of each test and checking of results.
   a. The individual responsible for Technical Review will be documented both on the electronic signature form for the run packet and the signature on the Blood Alcohol Report.

4. The records must be sufficiently detailed that in the absence of the analyst, another competent analyst or supervisor could evaluate what was done and interpret the data and would know the basis of the conclusions.

5. The date(s) of analysis will appear on the report.

6. The following information for each submission should be entered into the Laboratory Records (notes):
   a. Description of sample (including number of vials and matrix)
   b. Note about volume of sample
      i. if less than approximately 5 milliliters for blood vials
      ii. if less than approximately 10 milliliters for urine jars
   c. Condition of sample (sealed or unsealed)
   d. Kit number of the sample(s)/submission
   e. Notation about toxicology request on the envelope
   f. If a declaration form is submitted the analyst will note its presence.
   g. If a declaration form is submitted AND it contains additional information that is pertinent to the case, the analyst will note the information (eg. discrepancy or short draw) and maintain the declaration as an administrative record. See FSD.42.

7. Any remarks or discrepancies will be recorded in the Case File and on the final Report of Laboratory Examination.
   a. The following conditions should be noted, these include but are not limited to
      i. Any non-compliant conditions
      ii. Broken sample container(s) that would result in no analysis done
      iii. Insufficient sample
         1. for replicate analysis to be performed
         2. for any analysis to be performed
      iv. Sample not in a container provided by the laboratory (Non CCCSO Container)
      v. A urine sample with no void time indicated (as noted on the image of evidence envelope)
      vi. Expiration date of the kit (as noted on the image of evidence envelope)
      vii. Sample not tested

8. Only the approved procedures for analysis in the Blood Alcohol Technical Unit Manual will be used. Any discrepancies will be noted as indicated above.

9. Case notes will be single-sided on a page
10. For more information about retention of case records refer to the Division Manual.

11. In the alcohol unit, the analyst that prepares the report is the same as the analyst who tested the items. If an individual other than the analyst on the report interprets the findings, including testifying regarding the documentation (eg. Business Record or Official Record), that individual will document the review of the examination documentation in LIMS.

   a. The documentation should include:
      i. review of the report and notes
      ii. the purpose (eg. business/official record)
      iii. the reason for the review (eg. analyst retired, in training, on vacation, sick, etc.)

   b. For non-case related activity, click on the "activity button."
      i. Choose the appropriate activity
      ii. Add the time spent
      iii. Include specific details regarding the purpose of the activity performed.

   c. For cases that are associated with a lab number, the business record or official record activity should be related to the request.
      i. Under the request tab, select the request
      ii. Right click and select "activity"
      iii. Click the green "+" button
      iv. Choose the appropriate activity (court prep or court testimony)
      v. Add the time spent and the notes should document the review of the report and notes as well as the purpose and why a business or official record was done

C. Page Identification

   1. All note pages shall have the laboratory number, handwritten or computer generated initials of the examiner and the page number on the upper right hand corner of the page.

   2. The first and last page shall have the total number of pages.

D. Corrections

   1. Technical/Administrative Review Corrections:
a. Technical review corrections: All corrections will be recorded in LIMS in the request, in the "Notes: Reviewer" field.
   i. Identify the correction(s) and include the reason for the correction.
   ii. Record the date and technical reviewer's initials.
   iii. The analyst will enter what correction was made and when the correction was completed with their initials and date.

b. Administrative review corrections: All corrections will be recorded in LIMS in the request, in the "Notes: Reviewer" field.
   i. Identify any correction(s)
   ii. Record the date and administrative reviewer's initials.
   iii. It is recommended that the analyst enter when the correction was completed with their initials and date.

2. An electronic audit trail is maintained to view changes made electronically after a case has been draft complete.

E. Sequence "batch" or "run" procedure

1. The analyst will create a "Alc Sequence Data" request in LIMS. The Lab number will correspond to the year and instrument name (e.g. "2019 DCPE1" or "2019 DCPE2").
   a. Each run or batch will get its own request number.
   b. The requesting rep will be the analyst under the "Forensic Services Division" agency.
   c. The request date will be date that the packet is first entered into LIMS.
   d. No offense, evidence, or subject needs to be related to the request.

2. Under the request additional data form, enter the unique sequence number.

3. All documents generated for the run packet are placed into the request as attachments.
   a. Documents can be .pdf or other types of documents. Unlike casework images they are not limited to .jpg or .tif file types.
   b. If a non-contemporaneous edits are made to the documents, they must be preserved as separate file versions.
      i. Change the attachment names to reflect the version order (e.g. "packet ver1" versus "packet ver2").
      ii. Move the outdated version from the main request attachment folder to a sub-folder named "Drafts".
      iii. To create an attachment sub-folder, Right-click on the request folder. Select "Sub Folders | Add Sub Folder".
      iv. Only the final versions of any documents should remain in the main attachment folder for ease of technical and administrative review.
      v. Attachments can be moved by clicking the "Move" button under the attachments tab. This will remove the file from the original location and move it to the newly selected location.
1. Attachments are selected on the left-hand screen. Check the box of each attachment to be moved. More than one file can be moved at a time.

2. Select the destination on the right-hand screen. Note that attachments can be sent to a different lab number if that is edited at the top of the right-hand screen.

vi. Attachments can be copied by clicking the "Copy" button under the attachments tab. Copying functions similarly to the "Move" button, but will leave the original attachment in its place.

4. Enter Findings.
   a. In order to roll milestones, at least one finding must be entered.
   b. On the request tab, right-click on the request and choose "Edit Findings".
   c. Inside the module, right-click on the request number and choose "Add Result".
   d. The results type should be "Notes". Add text including any comments, initials, and date. Click Save.

5. Milestones
   a. The "run" request can be Draft Completed and signed as normal by the analyst.
   b. Any changes after the "Draft Complete" milestone should use the "Reject Findings" mechanism and enter notes within the reviewer's notes.
   c. The "run" request and documentation can be Tech. and Admin. Reviewed.
   d. The final report for the request will be a summary of packet information. This will be kept in LIMS but will not go out to ARIES.

END OF DOCUMENT
I. Policy: Reports will be written in accordance with the following guidelines.

A. Report Writing

1. Forensic alcohol analysis reports are to be prepared by the analyst at or near the time of completion of the analysis.

2. The results of each test or series of tests carried out by the laboratory shall be reported accurately, clearly, unambiguously and objectively, and in accordance with any specific instructions in the test methods. The results shall include all the information requested by the customer and necessary for their interpretation of the test results and all information required by the method used.

3. The results will be reported in a laboratory report of examination and include the information required by the customer necessary for their interpretation of the test result (the results of analysis) as well as the method used (analytical techniques). See BA.31 for instructions on how to generate electronic reports.

   a. If the request for analysis is cancelled by the requestor, the Laboratory will issue a report indicating no work was performed. See BA.31.

4. Reports will include information, unless otherwise indicated:

   a. Title of report or "Report of Laboratory Examination"

   b. Identity and location (address) of the testing laboratory

   c. Unique case identifier (laboratory number) and clear identification of the end of the report

   d. Name of the customer (submitting agency) the address of the customer is in the report annex.

      i. The address of the contracted agencies in Contra Costa County will be maintained by the Laboratory.

      ii. An effort will be made to obtain addresses for agencies that do not routinely use the services of the Drug, Alcohol, and Toxicology Section.

   e. Method(s) used or analytical techniques employed is in the report annex.
f. Description of, condition of and unambiguous identification of submitted evidence. This is the contents of the envelope. The tape-sealed condition of the outer packaging is also included.

g. The date of request is included on the report. The date of receipt of evidence is in the report annex.

h. The reference to the sampling plan is in the report annex.

i. Results of analysis including units of measurement

j. The disposition of the evidence will be stated in the report annex. Evidence associated with California Vehicle Codes (CVC) and tested for Alcohol will be kept for one year in the laboratory, then returned to the agency. All other evidence will be returned to the agency, unless otherwise noted on the report.

   i. Charges such as 655 H &N (Boating DUI), 192 PC (Vehicular Manslaughter), 215 PC (Carjacking), Accident, and Traffic will be evaluated on a case by case basis. The disposition will be noted on the report as a report comment if not returned to the agency.

k. Identity and signature (or electronic equivalent), for Alcohol Unit reports, the "approved by" signature refers to the individual who technically and administratively reviewed the case

l. Homogeneity is assumed among multiple vials within an envelope or kit as long as the vials were collected sequentially, from a single event, and into multiple similar containers, and having similar volumes. The reported results pertain to the entire item (all vials), not just the tested amount or the vial analyzed

5. In addition, reports shall, where necessary for the interpretation of test results, include the following, unless otherwise indicated:

   a. Any deviations in analytical techniques, will be included in the case notes

   b. Uncertainty of alcohol analysis, will be included in the report annex. For more information see BA.40.

   c. Opinions and interpretations. Results of alcohol analysis are conclusions. The report header will state "Examination Results and Conclusions".

   d. Additional information required by customer if necessary (eg. information contained on the request)

6. In addition, test reports containing the results of sampling shall include, where necessary, for the customer's interpretation of test results, include the following, unless otherwise indicated:

   a. The dates of analyses are typically from the dispensing until the data analysis

   b. Unambiguous identification of the item (contents of the envelope)

   c. Location of sampling or analysis is the crime laboratory, this in the report annex.

   d. The sampling procedure is in the Blood Alcohol Technical Unit Manual.
e. There are no environmental conditions that would affect sample selection, thus this is not applicable.

f. Any significant deviations from the casework protocol or sample selection plan in the SOP will be authorized by the Supervisor or Manager and be noted in the case notes

7. In addition, test reports will contain the following:
   a. Date of report (Draft Complete date in LIMS)
   b. If no definitive conclusions can be reached, the reason will be documented
   c. The author of the report will have conducted the examination or testing

8. Laboratory personnel who issue findings, including writing reports and providing testimony, based on examination results documented and generated by another person will document the review of examination documentation in LIMS.
   a. See BA.10 for a more detailed instruction.

9. For more information on the release of case report information refer to FSD.43.

10. The electronic release of reports will be done through the Automated Regional Information Exchange System (ARIES) and in accordance with FSD.43.

11. The format of reports will be in conformance with FSD.43.

12. Amendments to reports will be in conformance with FSD.43.

B. Expression of analytical results.

1. The average of the quadruplicate determinations is calculated to the fourth decimal place, and the result is reported by "dropping" or truncating the fourth decimal place of the mean. Results for blood, urine and vitreous samples are reported in terms of the blood alcohol equivalent concentration based on the number of grams of alcohol per 100 mL of blood, % Weight per Volume (W/V). Results for Cavity Fluid are reported in terms of alcohol concentration because of the unknown origin of the sample.

   a. The calculated mean % (W/V) blood alcohol concentration for each subject sample analyzed is reported by the Perkin Elmer Blood Alcohol Reporting System. The results are printed in the Summary Report and on the Blood Alcohol Report.

   b. Urine results are expressed as a blood alcohol concentration per Title 17. The results are based on the relationship: The amount of alcohol in 1 mL of urine is equivalent to that in 1.3 mL of blood. The Raw Average value is divided by 1.3 to obtain the Raw Converted Result. The corresponding blood alcohol level is reported by truncating the digit in the fourth decimal place, if present. Title 17 dictates the conversion factor to be used for urine.

   c. Vitreous results are expressed as a blood alcohol concentration. The results are based on the relationship: The amount of alcohol in 1 mL of vitreous fluid is equivalent to that in 1.27 mL of blood. The Raw Average value is divided by 1.27 to obtain the Raw Converted Result. The corresponding blood alcohol level is reported by truncating the digit in the fourth decimal place, if present.

   d. See BA.30 for more information about calculations.
2. **The (unconverted for urine and vitreous samples) analytical result with associated uncertainty will be reported on the annex to the report.**

3. Blood or urine samples from living subjects between 0.010% and 0.020% (W/V) will be reported as positive but below Limit of Quantitation.

4. Blood or urine samples from living subjects below 0.010% (W/V) and Postmortem blood samples below 0.020% (W/V) will be reported as "Not Detected".

5. For results that are above the reportable linear range (0.500%), the sample will be reported as "greater than" or "above" the upper limit of the reportable linear range or limit of quantitation.
   
   a. Urine and vitreous samples will be reported as "greater than" or "above" the upper limit of the reportable linear range or limit of quantitation when the unconverted result is above a 0.500%.

6. Where blood or urine samples are received not in compliance with prescribed collection, withdrawal, handling or preservation procedures the results are reported with an explanation of any non-compliant condition.
   
   a. Any remarks will be recorded in the Laboratory Examination Notes and on the final Report of Laboratory Examination. These remarks will include, but are not limited to, any non-compliant conditions (e.g., Broken Sample Container, Insufficient Sample for Replicate Analysis, Non CCCSO Container…).

7. The (LIMS) program will print a final Report of Laboratory Examination of the analysis. The following information will be maintained with the report as part of the case record for each case.
   
   a. Laboratory Examination Notes
   b. Forensic Alcohol Report
   c. Electronic Chain of Custody

8. For each set of samples examined, the following information will be stored in a file or binder:
   
   a. Forensic Alcohol Summary Report
   b. Calibration Plot for each column
   c. Traceability Worksheet
   d. Analytical Worklist
   e. Alcohol Batch Review List
   f. Blood Alcohol Gas Chromatography Worksheet and LIMS generated Alcohol Dispensing Tray Map (Optional)

END OF DOCUMENT
I. Policy: Reference Materials will be verified, labeled and stored in a manner to ensure the integrity of the standard.

A. Reference Materials

1. Reference Material (RM): A material, sufficiently homogeneous and stable with respect to one or more specified properties (properties can be quantitative or qualitative), which has been established to be fit for its intended use in a measurement process. A reference material is a substance of known concentration and/or composition from a known source. These are defined as follows:

   a. Certified Reference Material (CRM): A reference material characterized by a metrologically valid procedure for one or more specified properties, accompanied by a certificate that provides the value of the specified property, its associated uncertainty, and statement of metrological traceability

      i. Some material sold as CRMs have no stated evidence of traceability

   b. NIST Reference Material: A material issued by NIST with a report of investigation or a certificate.

      i. A NIST RM meets the ISO definition for a RM and may meet the ISO definition for a CRM.

   c. NIST-Traceable Reference Material™ (NTRM™): A commercially-produced reference material with a well-defined traceability linkage to existing NIST standards for chemical measurements established via criteria and protocols defined by NIST.

      i. A NIST NTRM may be recognized by a regulatory authority as being equivalent to a CRM.

2. Purchased NTRM (NIST-Traceable Reference Material (NTRM)).

   a. The NTRM standards used to establish the calibration curve during each "run" for the quantitation of ethanol in samples are considered to be a reference material and will be traceable to NIST (NIST-Traceable Reference Material). The documentation of traceability will be maintained in the Alcohol Unit.
B. Storage, Handling, and Use (ISO/IEC 17025:2005 5.6.3.4)

1. All reference materials will be stored, handled, and used in a manner that prevents contamination, deterioration and protects their integrity. This includes:

   a. Storing: NTRM standards and quality control solutions are stored within the laboratory according to the vendor instructions on the reference material label or certificate.

   b. Handling: Handle the reference material with care when removing it from its storage location and returning it to the proper location.

      i. Movement of reference materials within the laboratory is not considered transport.

   c. When using the reference material, staff will utilize good lab practices to prevent against contamination and to protect the integrity of the reference material. This may include:

      i. Proper labeling.

         1. See BA.14 for more information about labeling.

         2. The Purchased NTRM are labeled by the vendor with all relevant information including concentration and expiration date.

      ii. Abiding by any expiration dates on the reference material label or certificate. Reference material or any solution(s) will not be made from reference material past the expiration date.

         1. The expiration date that is on the reference material label or certificate is transferred to any secondary bottle or solution made from that reference material.

         2. If the laboratory assigned expiration date is before the expiration date of the reference material, the laboratory assigned expiration date will be transferred to any secondary bottle or solution made from that reference material.

      iii. Following any safety warnings on the reference material label or certificate.

C. Reference Standards (Balance Check Weights)

1. See BA.28 for the program and procedure for calibration of check weights. (ISO/IEC 17025:2005 5.6.3.1)

END OF DOCUMENT
I. Policy: The following procedure for the use, labeling, and storage of the NTRM Standard Reference Material will be followed.

A. Definitions and Usage of Known Alcohol Standards

1. Standards of known ethanol concentration used by the laboratory for blood alcohol determinations may be the following:
   
   a. A NIST-Traceable Reference Material (NTRM) is a commercially-produced reference material with a well-defined traceability linkage to existing NIST (National Institute of Standards and Technology) standards for chemical measurements established via criteria and protocols defined by NIST.
   
   2. The standard selected for casework will adhere to the performance criteria specified in BA.30.
   
   3. The vendor supplied NTRM Standards will only be purchased from vendors accredited and capable of providing NTRM alcohol standards.

B. General Information about NTRM Standard Solutions

1. Analysts working in the Alcohol Unit must be aware of the proper procedures for labeling, checking the reliability during a blood alcohol run, storing, and using solutions.
   
   2. The concentrations of the NTRM Standards are established by the vendor and documented in the Certificate of Analysis for each standard. The NTRM Standards are a reference material with traceability to NIST. See BA.13. (ISO/IEC 17025:2005 5.6.3.2)
   
   3. Purpose: NTRM Standards are water solutions of ethanol at specific concentrations. These solutions are used to calibrate the method with each set of samples analyzed and used in the calculation to determine the ethanol content of the unknown. (ISO/IEC 17025:2005 5.6.3.4)
   
   4. Labeling: All ampule bottles are be labeled by the manufacturer and should contain the following:
a. a solution identification number
   
i. The manufacturer's lot number on the NTRM Standard will become the Solution ID to be used with the Perkin Elmer TotalChrom Blood Alcohol Reporting System software. The last four numbers after the hyphen indicate the ethanol concentration of the solution.

   1. i.e. Solution ID format: **FN0216201601-0100**, indicates that the Cerilliant lot # is FN0216201601 and the concentration is 0.0100 % w/v.

5. **Check of Reliability**:

   a. The reliability of the NTRM standard will be checked by Gas Chromatography during each use.

   b. The concentration of the NTRM standards will be used to establish a calibration curve for each run. The four individual results for each NTRM Standard must be within ± 5% of the vendor established value.

6. **Expiration**: The NTRM Standards will be not be used for forensic alcohol analysis past the expiration date established by the manufacturer.

7. **Storage**: Store refrigerated according to the manufacturer's recommendations. (ISO/IEC 17025:2005 5.6.3.4)

C. **Procedure for Storage and Retention of NTRM Standards and Documents:**

1. Ampules will be discarded after the expiration date established by the manufacturer.

2. The vendor supplied documentation (Certificate of Analysis) will be maintained for at least 5 years or the current ASCLD/LAB accreditation cycle.

END OF DOCUMENT
I. Policy: The following procedure for the preparation, establishment, and storage of the Water-Ethanol Quality Control Solutions will be followed.

A. General Information about Quality Control (QC) Solutions

1. Analysts working in the Alcohol Unit must be aware of the proper procedures for labeling, checking the reliability, storing, preparing and using solutions.

2. It is recommended that at least one analyst, other than the analyst preparing the solution, initial and date the solution preparation paperwork to document that the procedures were followed and the paperwork was completed correctly.

3. A laboratory prepared Quality Control (QC) or a vendor purchased NTRM solution will be run at the beginning and end of each analytical sequence of samples, per Title 17, and may be interspersed throughout the sequence.

4. When a NTRM (NIST Traceable Reference Material) vendor purchased ethanol solution is utilized as a Quality Control solution within an analysis sequence, per Title 17, no laboratory establishment/verification is necessary. The NTRM ethanol solutions will be stored refrigerated or frozen as directed by vendor documentation. The NTRM solutions will not be used after the expiration date provided by the vendor. The Certificate of Analysis for each vendor purchased NTRM will be kept on file at the laboratory.

5. It is recommended, when the number of unknown samples allows for "interspersed" QC's within the sequence (more than 10 unknown samples), an NTRM vendor purchased ethanol solution will be run as an "interspersed" QC. It is recommended that various concentrations within the linear range of the Method be used.

6. The vendor purchased NTRM utilized as a Quality Control will not be from the same lot number (preferably, not the same vendor) as the NTRM standards used to calibrate the linearity of the method within the analysis sequence.

B. General Information for the Preparation of Quality Control (QC) Solutions

1. The concentrations of the quality control solution will be established by the method.

2. **Purpose:** The purpose of the Quality Control (QC) Program is to recognize any changes in the routine day-to-day response of the method. By monitoring this routine response, systematic errors that might arise in the method will be detected. The quality control reference material is a solution of water and ethanol. A separate
batch of quality control reference material shall be prepared for each gas chromatograph (DCPE1 & DCPE2).

3. **Labeling**: All bottles will be labeled with:
   a. A solution identification number (Lot number)
      i. The date, as Year, Month, Day (YYMMDD) and concentration (CONC) will be used as the Quality Control Reference Solution ID Number to be used with the Perkin Elmer TotalChrom Blood Alcohol Reporting System software- QCYYMMDD-CONC
         1. i.e. QC160112-1521 for a laboratory created water-ethanol QC solution with the concentration of 0.1521% prepared on 1/12/2016.
   b. Label the primary bottle "Quality Control" or "QC"
   c. GC number (DCPE1 or DCPE2)
   d. Date prepared
   e. Date to be discarded/expiration date
   f. Initials of preparer
   g. The determined alcohol concentration, % (W/V) value

4. **Check of Reliability for vendor purchased NTRM or in-house prepared Quality Controls**:
   a. The water-ethanol QC is tested with each analytical sequence. Passing criteria for an analytical result is as follows:
      i. +/- 5% (numerical value) of the expected target value for target concentrations between 0.080% ≤ X < 0.500%.
      ii. +/- 0.005 % (concentration) of the expected target value for target concentrations between 0.020% ≤ X < 0.080%.
   b. The reliability of the solution will be also be statistically evaluated on an on-going basis by checking the Measurement Assurance QC plots (see BA.42).

5. **Expiration**: Discard two years from date prepared.

6. **Storage**: Store refrigerated

| Table 1

</tr>
<tr>
<td>0.20</td>
</tr>
</tbody>
</table>

C. **Procedure for Laboratory Preparation of the Quality Control (QC) Solutions**:
1. Fill a 1 L volumetric flask partially with distilled water.

2. Using Table 1, determine the amount of absolute ethyl alcohol needed to make up 1 liter of the desired concentration of quality control reference solution. The alcohol concentration of this solution is between 0.080 and 0.200 g /100 mL of water, per Title 17.
   
   a. **The bottle identification (lot #-alpha numeric designator) should be tracked on the Reagent Preparation Log: Quality Control Reference Material** (see BA.44).

3. Using an adjustable (variable) pipette, measure the desired amount of purity checked absolute ethanol and add to flask.

4. Fill to the volumetric mark with distilled water. Stopper and mix thoroughly by repeated inversions of the flask.

5. Determine the value of the solution following the procedure below.

6. Transfer the solution to a properly labeled glass storage bottle.

7. Store in a tightly closed bottle under refrigeration when not in use.

8. This solution should be stable for up to two years.

9. **Fill out the Solution Log in the Alcohol Database. See BA.44**

D. **Procedure for Establishment of Laboratory prepared Water-Ethanol Quality Control (QC) Solutions:**

   1. After a suitable quality control reference material is prepared, as described above, it must be established.

   2. The four decimal mean value for each lot of quality control reference material is determined by at least 20 replicate analyses, at the rate of no more than two analyses per day, with the method used for forensic alcohol analysis.

   3. The established concentration should be the mean rounded to four decimal places (scientific rounding).

   4. The results of these analyses will be entered into the Alcohol Database. See BA.44

   5. Acceptable limits of variation are +/- 0.005% (W/V) from the mean. The mean and acceptable limits of variation are determined and entered into the log.

E. **Procedure for Using Laboratory prepared Quality Control (QC) Solutions:**

   1. A laboratory prepared Quality Control (QC) solution will be run at the beginning and end of each analytical sequence of samples, per Title 17. A sample set or analytical sequence is defined as a continuous sequence of blood or urine samples analyzed in replicate, up to a maximum of 40 samples.

   2. Sample results are reported only if analysis of the quality control reference material falls within the acceptable limits of variation. If analysis falls outside the acceptable limits of variation:
      
      a. Analytical results of the sample set will not be reported.

      b. The unsuccessful sequence should be entered in the Quality Assurance Correction Log.
c. The analyst will take remedial action to investigate and correct the source of the error.

d. No samples shall be analyzed for the purpose of forensic alcohol analysis until the error has been corrected, as demonstrated by return of the analysis of the quality control reference material to values within the acceptable limits.

e. The entire set of samples will be re-analyzed.

3. The results of all quality control analyses are recorded (can be electronic). The QC log contains the acceptable limits of variation and daily analysis results.

4. In addition the QC will be evaluated in such a way that trends are detectable and statistical techniques will be employed to review the data. The monitoring shall be at least monthly (see BA.42).

II. Policy: The following procedure for the verification and storage of the Blood-Ethanol "Matrix" Quality Control Solutions will be followed.

A. General Information for Blood-Ethanol "Matrix" Quality Control (BMQC) Solutions

1. The blood-ethanol quality control sample is a blood solution containing ethanol. The blood-ethanol "matrix" quality control solutions can be purchased from a vendor or created within the laboratory.

2. **Purpose**: The purpose of testing the blood-ethanol QC is to recognize any on-going matrix interference in the method.

3. The ethanol concentration of the quality control solution will be provided by the vendor's COA or verified by the laboratory. The concentration of the blood-ethanol quality control may be verified using the method.

B. Procedure for Preparing Blood Matrix Quality Controls

1. Blood matrix will be checked for interfering substances prior to preparation of the solution.

   a. Analyze a portion of any new lot of blank blood using the method. The blood may be used if it is free of ethanol and interfering substances.

2. Use an NTRM ethanol-water ampule to prepare the blood matrix quality control.

   a. The NTRM ampule used to make the BMQC, should not be the same NTRM ampule used to set the calibration curve for the analysis. Using an NTRM ampule from a different vendor is preferred. If the materials available in the laboratory do not allow for the use of different vendors, a different lot number from those used to set the calibration curve should be used when making the BMQC.

   b. Using the equation \( C_1 V_1 = C_2 V_2 \), BMQC concentrations should be prepared at a level within the method's linear range.

3. **Labeling**: All bottles will be labeled with:

   a. Vendor assigned lot # or laboratory lot #

   b. Concentration of the sample

   c. Expiration date
d. The Quality Control Reference Solution Identification Number to be used with the Perkin Elmer TotalChrom Blood Alcohol Reporting Software will be as follows: VENDORLOT#-CONC i.e. AAAA1214-1234 for vendor purchased BMQC's or CCCL150419-1672 for lab created BMQC's.

i. For example, UTAK3604-0800 for blood purchased from Utak with a lot # of 3604, at a concentration of 0.0800%.

ii. For example, CCCL160316-1517 for blood created in the Contra Costa Crime Lab on the date of 3/16/16, at a concentration of 0.1517%.

4. Check of Reliability: The blood-ethanol QC is tested by analyzing the samples periodically and ensuring the analytical results pass within:

a. +/- 5% (numerical value) of the expected target value for target concentrations between 0.080% \( \leq X \leq 0.500\% \).

b. +/- 0.005 % (concentration) of the expected target value for target concentrations between 0.020% \( \leq X < 0.080\% \).

5. Expiration:

a. Samples will be discarded after vendor's or laboratory's expiration date.

b. BMQC's prepared in the laboratory expire 14 days from the date of preparation.

6. Storage:

a. For vendor purchased BMQC's store according to vendor recommendation.

b. BMQC's prepared in the laboratory will be stored refrigerated.

7. Fill out the Solution Log for laboratory made QCs or enter vendor purchased QCs in the Alcohol Database. See BA.44

C. Procedure for Using the Blood-Ethanol Quality Control (BMQC) Solutions (Stored Frozen):

1. Thaw a frozen bottle containing the blood-ethanol QC and bring to room temperature. It is recommended to rock the sample for at least 30 minutes prior to dispensing sample for analysis.

2. Dispense the matrix QC in duplicate directly from the bottle.

3. The sample should be consumed the same day that it is thawed. Any unused sample will be discarded.

4. Sample results are reported only if the blood-ethanol quality control falls within the acceptable limits of variation. If analysis falls outside the acceptable limits of variation:

a. Analytical results of the sample set will not be reported.

b. The unsuccessful sequence should be entered in the Quality Assurance Correction Log.

c. The analyst will take remedial action to investigate and correct the source of the error.
d. No samples shall be analyzed for the purpose of forensic alcohol analysis until the error has been corrected, as demonstrated by return of the analysis of the quality control reference material to values within the acceptable limits.

e. The entire set of samples will be re-analyzed.

5. Any vendor supplied documentation will be maintained in the Alcohol Unit.

6. The blood-ethanol QC will be run on a periodic basis, at least once per month.

7. Blood-Ethanol QC samples will be discarded after their expiration date.

D. Procedure for **Storage and Retention** of Quality Control (QC) Documents and Solutions:

1. The vendor supplied documentation (Certificate of Analysis) will be maintained for at least 5 years or the current ASCLD/LAB accreditation cycle.

2. Portions of the Laboratory prepared water-ethanol QC solutions will be stored for at least 5 years after the expiration date.

END OF DOCUMENT
### I. Policy: The following procedure for the preparation of the Internal Standard will be followed.

#### A. General Information about Preparation and use of Internal Standard

1. Analysts working in the Alcohol Unit must be aware of the proper procedures for labeling, checking the reliability, storing, preparing and using solutions.

2. It is **recommended** that at least one analyst, other than the analyst preparing the solution, initial and date the solution preparation paperwork to document that the procedures were followed and the paperwork was completed correctly.

3. This reagent is used as the internal standard in the calculation of the quantitative value of ethanol in samples.

4. **Labeling:** All bottles will be labeled with:
   a. "n-Propanol, Internal Standard"
      i. The date and solution type will be used as the Solution ID Number to be used with the Perkin Elmer TotalChrom Blood Alcohol Reporting System software-**ISYYMMDD**.
      ii. i.e. IS990116, for an internal standard solution prepared on 1/16/1999
   b. date prepared
   c. date to be discarded/expiration date
   d. initials of preparer
   e. Specify storage condition (for example: room temperature or refrigerator)

5. **Check of Consistency:** A consistency check is being performed each time a new lot of Internal Standard is made. The successful completion of an analytical sequence with the new internal standard showing the passing of all standards and quality controls will serve as the check of consistency.

6. **Expiration:** The solution cannot be used past the labeled date of expiration of 3 months of usage.

7. **Storage:** The stock solution is stored refrigerated. When the internal standard is in use, it is stored in an amber (~2L) bottle attached to the diluter at room temperature within the hoods.
B. Procedure for Preparation of the Internal Standard Solution, 0.0025% n-Propanol

1. The exact concentration of the internal standard is calculated by volume during the preparation. The exact concentration of the n-propanol in the internal standard need not be determined as it is used in the formula for the calibration and the calculation, therefore the numerical value cancels out.

2. Partially fill a volumetrically marked plastic carboy bottle with distilled/de-ionized water. Add 50.0 µL of reagent grade n-Propanol, using a pipette, for each 2 liters of solution being prepared and dilute to the desired volume with distilled/de-ionized water.
   a. example: To prepare 16 liters of internal standard, add 400 µL of n-Propanol and dilute to 16 liters.
   b. the solution may be prepared in the last week of the month prior to the effective date and then used for the next three consecutive months.

3. Mix thoroughly to allow for equilibration.

4. A portion of the internal standard is placed into an amber (~2L) bottle attached to the diluter and will be replenished/replaced as needed for alcohol analysis from the refrigerated stock solution.

5. Complete the Solution Log in the Alcohol Database. (See BA.44)

6. See BA.44 for more information about populating the solution name of the internal standard in the Traceability Database.

END OF DOCUMENT
I. Policy: The following procedure for the preparation of the Resolution Solution Standard will be followed.

A. General Information about Preparation of Solutions
   1. Analysts working in the Alcohol Unit must be aware of the proper procedures for labeling, checking the reliability, storing, preparing and using solutions.
   2. It is recommended that at least one analyst, other than the analyst preparing the solution, initial and date the solution preparation paperwork to document that the procedures were followed and the paperwork was completed correctly.

B. General Information for Resolution Solution:
   1. Purpose: This solution is used for the determination of column resolution and efficiency.
   2. Labeling: All bottles will be labeled with:
      a. a sample identification number
         i. The letters "RS" and the date will be used as the Resolution Solution ID Number to be used with the Perkin Elmer TotalChrom Blood Alcohol Reporting System software-RSYYMMDD
            ii. i.e. RS160117, for a resolution solution prepared on 01/17/2016
      b. date prepared
      c. date to be discarded/expiration date
      d. initials of preparer
   3. Check of Reliability:
      a. After a new Resolution Solution is prepared the Resolution Solution will be run on the Blood Alcohol Method. All components of the resolution check solution must show separation under the normal gas chromatograph conditions used for analysis of samples.
      b. During each run, all components of the resolution check solution must be identified or "named" by the method according to the retention time of each
component on each column.

4. **Expiration**: Discard after two years.

5. **Storage**: Store refrigerated.

C. **Procedure for Preparation of the Resolution Solution:**

1. In a 1.0 liter volumetric flask:
   a. add approximately 500 mL distilled/de-ionized water
   b. add 0.2527 mL of reagent grade methanol
   c. add 0.2546 mL reagent grade isopropanol
   d. and 0.0637 mL reagent grade acetone
   e. add 0.2534 mL 200 proof ethanol to the mixture
   f. add 0.1273 mL of reagent grade acetaldehyde
   g. dilute to the mark with distilled/de-ionized water and mix.

2. Transfer to amber bottle and cap.

3. Complete the **Reagent Preparation Log in the Alcohol Database. (See BA.44)**

END OF DOCUMENT
I. Policy: The technical review process addresses the appropriate use of analytical controls; correct interpretation based on analytical controls; and the consensus of results between the examiner and the reviewer. This process ensures the conclusions of the analyst's are reasonable, within the constraints of validated scientific knowledge and supported by examination documentation. See FSD.17

A. Any significant differences in results by the reviewer must be resolved prior to issuing a final result and report.
   1. If a discrepancy is found, the report and notes along with the notation describing the discrepancy is returned to the analyst for correction.

B. Technical review shall be conducted by individuals having experience gained through training in the Alcohol Unit.

   1. Personnel who have completed and successfully passed the competency test for Forensic Alcohol Analysis on the current instrumentation and have been authorized by the Manager/Supervisor may perform technical review in the Alcohol Unit. However, based on the work load and experience of the analysts the Manager/Supervisor may choose to designate a specific Criminalist as Tech Reviewer in their absence.

C. Documentation of personnel authorized to perform technical review will be documented on the Training authorization checklist.

D. The technical reviewer of the sequence run packets will use the Alcohol Analysis Sequence Packet Review Checklist (See ALC.44) which includes, but may not be limited to, the scope listed in E. below for each sequence packet reviewed.

   1. The checklist will be signed, dated, and added in LIMS. (In the same request as the run packet)

E. The technical reviewer will consider the following scope, which include, but may not be limited to:

   1. Approved technical procedures used and documented, any deviations in analytical techniques will be included in the case notes.
   2. All run packet documentation are present
   3. Accuracy of test reports
4. The Traceability Worksheet properly documents the equipment used within the sequence
5. Results are properly transferred from notes to report
6. Perkin Elmer Forensic Alcohol Summary Report review
7. Ethanol standards' concentrations within tolerance
8. QC ethanol concentrations within tolerance
9. Blank sample is negative
10. Run Calibration Curve is within tolerance
11. Sample type (example: blood or urine) is entered properly
12. Any "failed" sample analysis listed over 5% is flagged
   a. Ensure that a quality log entry is made if applicable
F. The Technical Reviewer may use a Report Review Checklist ALC.33 encompassing the scope listed above.
   1. It is recommended that any newly competent analyst review ALC.33 prior to submitting cases for technical review.
   2. It is recommended that any technical reviewer that is not currently proficiency tested to reference ALC.33 upon reassignment to this task.
G. The author of the report may not conduct the technical review.
H. The Administrative review milestone in LIMS reflects the technical and administrative review of the case.
   1. The signature of the reviewer on the laboratory report designates approval.
II. Policy: The administrative review process addresses the case file for format and content. The reviewer verifies the requested examination has been performed and the basis for the conclusions is supported in the notes. See FSD.18
   A. It is the responsibility of the analyst, not the Administrative Reviewer, to prepare and present a completed report package that complies with the Laboratory's policies and is free of errors.
   B. All reports will be technically and administratively reviewed by a Manager/Supervisor or a person designated by the Manager/Supervisor.
   C. The individual administratively reviewing the report will not be the person who authored the report.
      1. Personnel who have completed and successfully passed the competency test for Forensic Alcohol Analysis on the current instrumentation and have been authorized by the Manager/Supervisor may perform administrative review in the Alcohol Unit. However, based on the work load and experience of the analysts the Manager/Supervisor may choose to designate a specific Criminalist as Administrative Reviewer in their absence.
   D. Documentation of personnel authorized to perform administrative review will be documented on the Training authorization checklist.
E. The Administrative Reviewer may use a Report Review Checklist ALC.33 encompassing the scope listed below.

1. It is recommended that any newly competent analyst review ALC.33 prior to submitting cases for administrative review.

2. It is recommended that any administrative reviewer that is not currently proficiency tested to reference ALC.33 upon reassignment to this task.

F. Administrative review will take place prior to the release of the report. Refer to FSD.43 for release of information verbally.

G. The administrative reviewer will consider the following scope, which includes, but may not be limited to:

1. All information is correct on case report header (agency case number, name, agency, offense, request date, etc.)

2. The administrative and examination records are uniquely identified.
   a. The unique identifier is the laboratory number.
   b. There is a clear identification of the end of the report.

3. Proper report format followed per Division policy

4. The signature (or electronic equivalent) of the author appears on the report

5. Clarity of conclusions in report
   a. Date(s) of analysis are stated accurately
   b. Uncertainty of analyses are included in the report annex.

6. Method(s) used or analytical techniques employed listed on report

7. The description and identification of submitted items is clear

8. The tape-sealed condition of the outer packaging is noted

9. Chain of custody documented in report and LIMS.
   a. Chain of custody on envelope is consistent with LIMS.
   b. The date of receipt of evidence is in the report annex.

10. The date of request is included on the report.

11. Evidence items listed on request form correspond to reported items

12. The notes are legible

13. Correct grammar and spelling

14. All handwritten corrections to notes shown by initialed single strike-out, if applicable

15. All handwritten notes in ink, if applicable

16. All notes pages, including data, are properly marked with lab number, date and initials
17. The first and last notes page includes the total number of pages
18. Applicable worksheets used
19. Disposition of the evidence is included in the report.
20. Any communication is documented in the notes or telephone log documents and may be imaged into the case notes.

### I. Policy: Managers/Supervisors or persons designated by the Manager will review the testimony of their staff annually according to the following procedure.

A. Court Critique Forms are available to staff members to encourage input from judges, attorneys, or peers regarding employee performance for courtroom testimony (FSDF.03).

B. There are other means of review of testimony that include, but may not be limited to, reviewing transcripts, or interview of an individual who witnessed the testimony. Refer also to the Division Manual policy on Courtroom Testimony Monitoring (FSD.17 and FSD.26).

C. Individuals shall be given a technical review of their courtroom testimony by a technically competent person. Feedback shall be documented through an internal court testimony review form (FSDF.02). A copy shall be provided to the analyst.

D. If performance is less than satisfactory, the Supervisor/Manager will gather appropriate information; this may take the form of interviewing the person filling out the Court Critique to determine the extent of the unsatisfactory performance.

1. The Supervisor/Manager will address the performance with the analyst if the performance is unsatisfactory.

2. Any remedial action taken will be documented; this may take the form of a corrective action if necessary.

E. The records of testimony monitoring shall be retained not less than one full ANAB accreditation cycle.

F. If an individual does not testify in the calendar year, the Supervisor/Manager will document this according to the Division Manual policy.

### II. Policy: Proficiency samples will be submitted to each analyst who performs testing, or an activity which contributes to the quality of testing, on a yearly basis.

A. These samples will be supplied by an outside agency, internally, or blind.

1. See BA.41 for more information on using case samples or re-using samples for proficiency testing.

B. When participating in proficiency testing, the Alcohol Unit's own approved and documented test procedures shall be used.
C. Criteria for passing blood/urine alcohol proficiency:

1. Criteria for passing an external (vendor provided) proficiency:
   a. The expectation is that staff correctly identify ethanol and its concentration.
   b. If the ethanol concentration is quantitated and the vendor provides statistics (grand mean and standard deviations), the laboratory quantitative value should be within 2 standard deviations of the grand mean. Values between 2 and 3 standard deviations will be evaluated and action may be taken by the laboratory. Values outside of 3 standard deviations are considered unsuccessful and corrective actions will be taken and documented through the QA Action process.
   c. If the vendor does not provide statistics, the laboratory quantitative value will be within:
      a. For target concentrations between 0.080% \( \leq X \leq 0.500\% \) the criteria is the mean value of the sample results must be within +/- the current Method UOM (Uncertainty of Measurement; e.g. ~ +/- 6.27%) from the target (spiked) concentration provided by the vendor.
      b. For target concentrations between 0.020% \( < X < 0.080\% \) the criteria is the mean of the sample results must be within +/- 0.005 (% concentration) from the target (spiked) concentration provided by the vendor.

2. For an internal proficiency (samples prepared in-house):
   a. The mean of the analyst's results must be within:
      i. +/- 5% (numerical value) of the expected target value for target concentrations between 0.080% \( \leq X \leq 0.500\% \).
      ii. +/- 0.005 (% concentration) of the expected target value for target concentrations between 0.020% \( \leq X < 0.080\% \).

3. If the analyst's results do not meet the passing criteria, the incident will be investigated and appropriate action will be taken, this may include issuing another test or providing remedial training. The unsuccessful test will be documented in a QA Action.

D. See Division Manual policy on Proficiency Testing for more information (FSD.23)

E. The laboratory shall maintain records of proficiency testing, including:

1. The test set identifier
2. How samples were obtained or created
3. Identity of the person taking the test
4. Date of analysis and completion
5. All data and notes supporting the conclusions
6. Proficiency test results
7. Discrepancies noted (refer to the Division Manual Policy)
8. Indication that performance has been reviewed and feedback to the analyst
9. Details of any corrective action taken (refer to the Division Manual Policy)

F. Records shall be retained not less than one full ANAB accreditation cycle.

END OF DOCUMENT
I. Policy: New procedures or methods of analysis must be validated or verified before use in casework.

A. Any new method or procedure or adjustment to a current procedure must be tested in the laboratory to insure that the method or procedure works, the verification or validation shall be as extensive as necessary to meet the needs of identification and quantitation of ethanol in biological samples. The laboratory shall record the results and document the procedure. Approval of the method for use in casework is documentation that the method is fit for forensic alcohol analysis.

B. A Quality Action Request, or equivalent, will be generated and given to the Manager/Supervisor to be approved; then forwarded to the Quality Assurance Coordinator.

C. For more information on validation of methods see the Division Manual (see FSD.27).

D. Selection of Methods

1. The forensic alcohol analysis will be performed using the semi-automated gas chromatograph method for quantitation of ethanol in blood, urine and vitreous samples. This is appropriate for the reporting ethanol concentrations in samples and meets the needs of the customer. The semi-automated gas chromatograph method will be validated to allow for the quantitation of ethanol in blood, urine and vitreous samples. The objective and scope of analysis is the quantitation of ethanol in blood, urine and vitreous samples.

2. The customer shall be informed of the method chosen by the Alcohol Unit by listing the analytical technique on the report.

E. The following factors shall be taken into account in developing test methods and procedures:

1. Human factors

2. Accommodation and environmental conditions

3. Test and calibration methods and method validation

4. Equipment

5. Measurement traceability

6. Sampling
7. **The handling of test and calibration items**

F. Guidelines for Performance Verification

1. The purpose of performance verification is to ensure that a previously validated method, or method from a manufacturer, will work in the Laboratory with the Laboratory's personnel and instrumentation.

2. Performance verification should consist of evaluation of the validated method (without making significant changes to sample preparation or instrument parameters) and demonstrating that the standards or controls have been carried through the process and yielded the expected results. Prior to implementation of a validated method new to the laboratory, or a method from a manufacturer, the reliability of the procedure shall be documented in-house against any documented performance characteristics of that procedure. Records of performance verification shall be maintained.

3. Qualified personnel criteria for a Performance Verification:
   a. For an instrument verification, an analyst who is competent in the unit can complete a performance verification.
   b. An analyst who is competency tested or in training can acquire data to be evaluated for the performance verification.
   c. For new technology (such as instrumentation), an analyst who is competent in the unit can complete a performance verification.

G. Guidelines for Method Validation

1. The purpose of method validation is to demonstrate that the method is suitable for the quantitation of ethanol in samples and is reproducible by the Laboratory's personnel with the use of the Laboratory's instrumentation.

2. Method validation is required on new methods, methodology or procedures. Validation is the confirmation the requirements for quantitation of ethanol in samples is fulfilled by examination of objective evidence.

3. The following SWGTOX criteria were taken into account for the current method and assessed for the use of quantitation of ethanol in samples and is relevant for the customer needs:
   a. specificity and interference
   b. bias and precision (repeatability and/or reproducibility)
   c. calibration model & the linearity of the method including the range and accuracy of values obtained from the validated method
   d. estimation of the uncertainty of measurement
   e. carryover
   f. standards stability
   g. the detection limit (LOD) and limit of quantitation (LOQ)
   h. process stability and heat stability
4. Methods developed by the laboratory for its own use will be a planned activity and assigned to qualified personnel. Plans will be updated as development proceeds and effective communication between the analyst and Supervisor/Manager will be ensured.

5. Qualified personnel criteria for a Method Validation:
   a. For a method validation, an analyst who is competent and currently proficient in the unit can plan and coordinate a method validation.
   b. An analyst who is competency tested or in training (with supervisor/manager approval) can acquire data to be evaluated by a competent analyst for a method validation.
   c. For new technology (such as instrumentation), an analyst who is competent and currently proficient in the unit can plan and coordinate a method validation.

H. Software

1. When computers or automated equipment are used for the acquisition, processing, recording, reporting, storage or retrieval of test data, the laboratory shall ensure that laboratory configured software is suitably validated and documented as being adequate for use. In the Alcohol Unit, this may include, but is not limited to:
   a. TotalChrom Blood Alcohol Reporting Software
   b. LIMS Crystal Reports for Blood Alcohol Reporting

2. Documentation of software validation will be reviewed by a Supervisor/Manager prior to approval for use. If the software is controlled or approved through the use of a software log, the approval initials in the log will document the review and approval of the validation. If the software is controlled or approved through PowerDMS, the electronic approval signature will document the review and approval of the validation.

3. See BA.29 for more information.

I. Equipment

1. Equipment that is new to the laboratory shall be properly evaluated to ensure its reliability. The evaluation will be as extensive as necessary to meet the needs of the Alcohol Unit.
   a. If the type of equipment already exists within the laboratory and additional equipment of the same type is obtained, a check of the equipment may be satisfactory to ensure its reliability. This check shall ensure that the equipment is operating properly. This will be evaluated by the Supervisor/Manager.
   b. If the equipment is a new methodology or the operation is significantly different from equipment already in the laboratory, validation, training and an associated competency may be necessary. This will be evaluated by the Supervisor/Manager. The competency test will meet the requirements in the ASCLD/LAB Supplemental requirement 5.2.6.2.1.

2. Before being placed into service, equipment shall be calibrated or checked to establish that it meets the laboratory's specification requirements. It shall be
checked or calibrated before use in casework. See _BA.21_ for information on equipment.

END OF DOCUMENT
I. Policy: All equipment used for alcohol analysis is kept in good working order and routinely checked for accuracy and precision by an analyst trained in Forensic Alcohol Analysis.

A. The Alcohol Unit is furnished with the measurement equipment for the analysis of alcohol in samples for the correct performance of tests. This measurement equipment includes:

1. Computer with Windows 7 operating system or compatible operating system capable of running the following software:
   a. TotalChrom Navigator software v. 6.3.2.0646 Copyright 2008
   b. Turbo Matrix Headspace Autosampler software v. 2.5.0.0125

2. PerkinElmer Clarus 580 Gas Chromatograph with a flame ionization detector and Blood Alcohol Columns ELITE-BAC-1 Advantage and ELITE-BAC-2 Advantage (Perkin Elmer), 0.32 mmID, 1.8 µm df, 30 meter capillary column or equivalent column.

3. Perkin Elmer Turbo Matrix 110 Headspace Sampler

4. Hamilton digital dilutor with hand probe, Model 500, 600, or equivalent, used to pipette samples and dispense internal standard.

5. Eppendorf Pipettors, or equivalent, adjustable volume: 100 µl to 1000 µl and 500 µL to 2500 µl used to prepare solutions.

6. Balance, Analytical, capable of weighing 0.1 mg

7. Traceable VWR Digital Thermometer or equivalent

B. The Alcohol Unit is also furnished with the test equipment and supplies required for the correct performance of tests. This testing equipment and laboratory supplies include:

1. Volumetric flasks, Class A: 2 liter, 1 liter, 500 mL, 250 mL, 100 mL and 50 mL sizes used for preparation of solutions

2. Injection vials: 20 mL glass vials with butyl rubber stopper, or equivalent, and aluminum seals, 20 mm closure size.

3. Hand crimper, manual or automatic, 20 mm seal size.
4. Plastic carboy bottle that holds a minimum of 16 liters used to prepare and store the internal standard.

5. Oven capable of operating with stability as low as 40°C and as high as 105°C.

6. Ten Broeck Tissue Homogenizer, all glass, or equivalent, various sizes used to homogenize clotted blood specimens prior to analysis.

7. Desiccator containing a desiccant, such as activated silica gel.

8. Vials (blood sample vials that do not contain an anticoagulant or preservative, or small screw top glass jars) used to split samples for referee analysis.

9. Standard laboratory glassware such as beakers, watch glass, dropper bottles, graduated cylinders, magnetic stir bars, weigh boats and glass storage bottles.

C. The measurement equipment and software used for testing is capable of achieving the accuracy required for quantitative testing of ethanol in samples.

D. Equipment will be operated by authorized personnel. The authorization will be documented on the authorization checklist. See Blood and Urine Training.

E. Before being placed into service (to perform casework), equipment will be calibrated or checked to establish that it meets the laboratory's requirements.

1. All dilutors, dispensers/titration, pipettes, balances and thermometers will be calibrated before being used in casework.

2. The measurement equipment (DCGC-FID, volumetric glassware) shall meet the vendor's performance check criteria or the laboratory criteria before being used in casework. The check criteria will be documented.

F. After being placed into service, equipment will be calibrated or performance checked to establish that it continues to meet the laboratory's requirements. If equipment does not pass a performance check criteria or calibration tolerances (eg. AS FOUND data listed on the calibration certificate), an evaluation of the equipment's impact on casework will be completed and documented.

1. When an evaluation determines that the reported results are not affected, a level 2 log entry will be cross referenced in the equipment calibration log.

2. When an evaluation determines the reported results are affected, the impact will be documented through the QA ACTION process. See FSD.15

G. Each piece of equipment and its software significant to the test result in the alcohol unit is uniquely identified. See below and Software.

H. Dual Column Gas Chromatograph Flame Ionization Detector (DCGC-FID)

1. Each uniquely identified DCGC-FID in the Alcohol Unit has an accompanying maintenance binder that includes, unless otherwise indicated:

   a. The identity of the equipment (Laboratory assigned identifier) and software (version number or equivalent)

   b. The manufacturer's name and serial number or other unique identification

   c. The checks that the equipment complies with specifications are filed in the Alcohol Unit
d. The location of the equipment is the Alcohol Unit

e. The dates, results or reports of any adjustments

f. Any damage, modification, malfunction or repair

2. The instructions for use and the maintenance plan are contained in the Blood Alcohol Technical Unit Manual. See:

a. DCGC-FID-Routine Maintenance

b. DCGC-FID-Literature References

c. Analysis of Samples by DCGC-FID

d. Using LIMS

I. Balance

1. The uniquely identified balance in the Alcohol Unit has a maintenance binder that includes:

a. The identity of the equipment

b. The manufacturer's name and serial number or other unique identification

c. The monthly Calibration checks that the equipment complies with specifications

d. The dates, results and copies of reports or certificates of calibrations or any adjustments.

e. Any damage, malfunction or repair

f. Documentation of maintenance carried out

2. The instructions for use and the maintenance plan are contained in the Blood Alcohol Technical Unit Manual. See:

a. **Balances**

3. For any off-site service, the balance will be transported to the external calibration laboratory in a secure packaging to prevent any damage.

J. Diluters-Hamilton 500 or equivalent or Variable Eppendorf or equivalent

1. Each uniquely identified diluter, dispenser or pipette in the Alcohol Unit has a maintenance binder that includes:

a. The identity of the equipment

b. The manufacturer's name and serial number or other unique identification

c. The Calibration checks that the equipment complies with specifications

d. The dates, results and copies of reports or certificates of calibrations or any adjustments.

e. Any damage, malfunction or repair

f. Documentation of maintenance carried out
2. The instructions for use and the maintenance plan are contained in the Blood Alcohol Technical Unit Manual. See:
   a. Diluters, Dispensers and Pipettes

K. Glassware and Thermometers

1. Each uniquely identified thermometer and critical volumetric glassware that is in the Alcohol Unit will have the following records:
   a. The identity of the equipment
   b. The manufacturer's name and serial number or other unique identification
   c. The Calibration checks that the equipment complies with specifications
   d. The dates, results and copies of reports or certificates of calibrations or any adjustments.
   e. Any damage, malfunction or repair
   f. Documentation of maintenance carried out

2. The instructions for use and the maintenance plan are contained in the Blood Alcohol Technical Unit Manual. See:
   a. Glassware and Thermometers

L. Equipment that needs repair shall be taken out of service. It shall be clearly marked or labeled as being out of service until it has been repaired and/or shown by calibration or test to perform correctly. If there is a concern that the defect affected previous tests, the laboratory shall investigate.

M. See Balances, Diluters, Dispensers and Pipettes, and Glassware and Thermometers for information on calibration, and intermediate checks. See Balances for the calibration program for balance check weights.

N. Test equipment will be handled according to procedures in the Blood Alcohol Technical Unit Manual such that the equipment is safeguarded from adjustments which would invalidate the test and/or calibration results. If any damage, malfunction or repair is needed the equipment will not be used for casework until remedial action is taken.

O. Accommodations and Environmental Conditions

1. The laboratory is in a climate controlled building and the lighting and energy sources are suitable for alcohol analysis

2. There are no environmental conditions in the technical requirements for forensic alcohol analysis that need to be documented or monitored

3. If power is lost to equipment, analysts will ensure that it is working properly prior to resuming alcohol analysis.

4. Reference materials that require refrigeration are stored refrigerated and the refrigerators are monitored. See TOX.17 for more information on monitoring.

5. Analysts are responsible for maintaining a clean work area and general lab cleanliness. Trash is picked up from the lab and routine cleaning is performed by General Services Department (GSD). Non-routine cleaning (e.g., floor waxing, etc.) is scheduled with General Services Department (GSD).
I. Policy: The procedures for routine maintenance should be followed.

A. General Maintenance:

1. All maintenance must be logged in the Maintenance Binder. See BA.21 Care and Maintenance of Equipment and Environmental Conditions.
   a. When an instrument is not in use, an entry should be made in the Perkin Elmer System Maintenance Log indicating when it is out of service and when it is back in service.
   b. If the instrument is out of service for an entire calendar month, the Monthly Checks do not need to be performed. Monthly Checks will be performed prior to casework analysis.

B. Preventative Maintenance: Clarus 580 Gas Chromatograph:

1. Analysts should monitor chromatography from run data routinely.
2. When columns are showing poor chromatography (asymmetrical peaks, wider peak width, tailing...etc.) it may be an indication that column maintenance is necessary.
3. For further information regarding general trouble-shooting refer to the GC-FID Literature References.
4. Changing the Column-Inlet End:
   a. Turn off injector temperature by pressing A-CAP tab and pressing Heater Off on the touch pad for the GC.
   b. Make sure the carrier gas is set to PSI 5 and the oven is turned Off.
   c. Let temperature equilibrate for 15 min. and then open oven.
   d. When only the back column (Column B or BAC-2) is being serviced, analysts may need to remove the front column to gain access to the back column within the oven of the GC. This can be done by removing the entire front column and capping the ends with septa,
   e. Remove the old column by cutting the column on the detector end and plugging it with a septum to isolate the transfer line so no hot air goes in.
   f. Take out the inlet end, save the column nut.
g. The blood alcohol column does not have a guard column, either end of the column may be attached to the inlet.

h. Unwind a little of the column. Cut a septum into quarters with a scalpel so the space on the column can be marked.

i. Put on a septum, then the 1/8 inch column nut, then the 1/8 graphite vespel injector ferrule. The beveled end of the ferrule goes against the column nut.

j. Cut 10 cm off the column, look at the column under the magnifying glass, it should be smooth and not jagged.

k. When cutting the column with the column cutter, the rougher side of the column cutter should be used to cut the column.

l. Wipe off the column with a few drops of methanol on a lint free tissue.

m. Adjust the septum up the column until there is 44-51 mm of column sticking out from the end of the column nut.

n. Screw in the nut to the inlet end. Hand tighten inlet nut, then using a 1/4-inch wrench, tighten the fitting until the column cannot be pulled out of the fitting.

o. Look for the detector end of the column, cut the end and turn on the pressure. Stick the detector end of the column in a vial of methanol and look for bubbles to make sure there is pressure throughout the column.

p. Make sure the pressure is on before conditioning the column. Set the pressure to 5 PSI.

q. Turn Oven temperature to 120°C for two hours to condition the column.

5. **Changing the Column-Detector End:**

a. Unscrew the old nut on the detector end with the wrench; take out the old column from the transfer line leading to the FID.

b. Cut the old column on both sides of the nut and remove the old ferrule out, clean out the inside of the column nut (can use canned air to clean any debris) and the column nut may be reused.

c. Cut a rubber septa into 4 pieces

d. Insert a piece of the septum onto the new column (it is a guide)

e. Insert the 1/16 inch column nut

f. Insert the 1/16 inch graphite ferrule (the flat part goes into the nut)

g. Then cut the column accordingly (around 1-3 inches), check that the cut is straight and not jagged.

h. Back up the septum by how much the column was sticking out (approximately 7.1-7.4 cm), wipe down the column with a methanol kimwipe.

i. Insert the column into the detector, then move the septum and nut up to the screw and lightly screw the nut on
j. Hold the detector fitting steady with one of the 7/16-inch wrenches and gradually tighten the column nut with the other wrench. Tighten the column nut until only until the column cannot be pulled out of the nut. **DO NOT OVERTIGHTEN THE NUT.**

k. Push the septum up against the nut and close the door to the oven.

6. **Clipping the Column:**

   a. The procedures for changing the column above can also be used to "clip" the column to extend the life of the column. Follow procedures above for the "Injector End" instructions (without replacing the column). Consider clipping the column approximately 10 inches from the injection end at a time. Run samples to compare chromatography for any improvement. If poor chromatography persists after consecutive column clippings, consider replacing the column. Note: Every time the column length is changed it must be conditioned according to the instructions in "changing the column-inlet end" above.

   b. When clipping the column is necessary, the analyst should remove the entire front column to gain access to the back column within the oven. It is possible to only remove the inlet end of the front column and access the back column for clipping, however much care is needed to keep the front column free from harm (air and breakage). This can be done by capping the front end with a septum and keeping the front column from moving while the back column is being serviced.

   c. The injector end of the column may become contaminated or get active sites over time. Remove 1 or 2 loops from the inlet side to bring the column to acceptable performance. One loop is approximately 50 centimeters

   d. The column is replaced into the inlet.

   e. For further information, refer to **GC-FID Literature References**

7. **It is recommended to run a method to bake out the column to prevent water retention in the GC column.** The BAC SHUTDOWN.MTH is part of the sequence and is run after all vials are injected. This method bakes out the column and shuts off the FID.

C. **Resolution Solution-Column Performance Check:**

1. **Scope** of the Resolution Solution Check

   a. **Whenever a column is clipped or replaced the Resolution Solution must be run to obtain the updated retention times for all compounds within the Resolution Solution.**

   b. Separation of volatile components is checked by analysis of a resolution check solution.

2. **Procedure** for the Resolution Solution Check

   a. Run the Resolution Solution using the Perkin Elmer Blood Alcohol Reporting System program using the BAC method.

   b. Use the .RAW or .RST file created for each column to update the retention times in the BACa and BACb methods prior to running any casework
samples.

3. **Criteria** for the Resolution Solution Check
   
a. All components of the resolution check solution must show separation under the normal gas chromatograph conditions used for analysis of samples.

   b. All components of the resolution check solution must be identified or "named" by the method.

D. Preventative Maintenance-Turbomatrix 110 Headspace Autosampler:

1. Change the O-rings of the headspace autosampler approximately every 3000 injections. Cleaning/changing the needle assembly can also be done while changing the o-rings.

   a. Consult the appropriate literature source for directions on cleaning the needle or changing the o-rings. See *GC-FID Literature References*.

2. Reset the injection counter after each replacement of O-rings by doing the following:

   a. On TurboMatrix 110 touch panel choose Tools -> Preferences -> Config -> Reset Counter. The maintenance alarm should be set to 3000.

   b. Consult the appropriate literature source for more information. See *GC-FID Literature References*.

E. Preventative Maintenance-Dell Computer Workstation:

1. To maintain the computer operating as efficiently as possible, the following should be performed:

   a. Back-up Data including C:\GC1\DATA or C:\GC2\DATA folder onto either a CD, DVD, or external hard drive will be done periodically. It is suggested that this is done annually.

   b. Archive old data as needed by organizing previous year's data into separate folders.

END OF DOCUMENT
I. Policy: All instruments used for alcohol analysis are kept in good working order to ensure their reliability. Below are the procedures that should be followed for the care and maintenance of diluters and pipettes in the Alcohol Unit. (ISO/IEC 17025:2005 5.5.3, 5.5.5.c, 5.5.5.g, 5.5.6)

A. New or Serviced Diluters or Pipettes

1. A diluter (e.g. Hamilton) or pipette (e.g. Eppendorf) new to the laboratory, or a diluter or pipette that has been serviced or has undergone substantial maintenance will be calibrated by an ISO 17025 compliant vendor before being used in casework (ISO IEC/17025:2005 5.6.2.1.1, Supplemental 5.6.1.1).

B. Yearly Calibration

1. The diluters and pipettes in the Alcohol Unit will be calibrated yearly by an external calibration service that is ISO 17025 compliant. The certificates obtained will contain the measurement results including the measurement uncertainty and/or statement of compliance with an identified metrological specification (ISO IEC/17025:2005 5.6.2.1.1).

   a. If the equipment was found to be out of tolerance, an evaluation will be done to determine if there was any effect on casework.

2. The laboratory will maintain copies of the certificates obtained for at least the current five year accreditation cycle.

3. The external calibration service will affix labels to each diluter or pipette to indicate the calibration status, including the last calibration and the recommendation for the next calibration (ISO IEC 17025:2005 5.5.8).

C. Accuracy or Calibration Check (ISO/IEC 17025:2005 5.5.10)

1. The diluters and pipettes in the Alcohol Unit will be checked to ensure that they are operating satisfactorily. See below for the specifications for each type of equipment. This procedure shall be performed by a Criminalist qualified to perform Forensic Alcohol Analysis.

2. The results of the check will be maintained in the Alcohol Unit.
3. If the diluters or pipettes fall outside the acceptable tolerance range the equipment must be taken out of service. Calibration may be performed by an external calibration service meeting the requirements of ISO 17025:2005 5.6.2.1.1.

D. Hamilton Diluter (Microlab 600 series)

2. The Hamilton Microlab 600 series Digital Diluter is routinely used to dispense known quantities of sample mixed with known quantities of Internal Standard (n-Propanol or Buffer) for forensic alcohol analysis. The Hamilton 600 series is an instrument which accurately and precisely aspirates and dispenses fluid at the touch of a hand probe button or the tap of a foot switch.

3. The Hamilton Diluter as maintained within the laboratory is a dual liquid solution dispensing unit which combines liquid samples into a single mixture by incorporating two syringes each controlling the amount of each solution volume to be dispensed. One syringe extracts and dispenses solution from a bottle containing internal standard and the other extracts from a desired sampling source.

4. The Hamilton Diluter Microlab 600 series is an easily-programmed instrument ideal for performing multiple dilute and dispense methods. The programmed method is used to dispense the samples.

5. How a Hamilton Microlab Diluter works:

   ![Figure 1: A simple dilution](image)

   a. **Step 1:** Fill the left syringe with the programmed amount of solvent (diluent) from the reservoir and aspirate the programmed amount of concentrated sample into the end of the probe using the right syringe.

   b. **Step 2:** Dispense the sample and solvent into a vial to complete the dilution.

6. The instructions for general use of the Hamilton Diluter are as follows:

   a. The Hamilton Diluter needs to be plugged in and the power switch turned ON.

      i. The 600 series unit has a power button on the bottom front of the drive unit.
b. Make sure the correct bottle with the proper Internal Standard solution is connected to the left syringe unit prior to dispensing.

c. Flush the syringe several times (3-4 times) with the solution within the bottle to clear out any residual solution/bubbles in the syringe and tubing.

d. There are preset methods programmed into the controller and base unit for dispensing specific volumes.
   i. ALCOHOL for forensic alcohol analysis: 1.25mL left syringe for Internal Std and 0.25mL right syringe for Sample.
   ii. For the Hamilton 600 series:
      1. From the MAIN MENU, select CUSTOM METHODS.
      2. Select the desired method (i.e. highlight ALCOHOL), then select RUN.
      3. If the syringe(s) has fluid inside, an "Empty Syringes" screen is displayed. Direct the probe towards a waste area and select OK. Any fluid in the syringes on the drive unit will be purged.

e. Aspirate sample using hand probe by pressing the probe wand or foot pedal.

f. Dispense the preset volume into desired vial by pressing the probe wand button or foot pedal one time. This will deliver the sample and the internal standard together.

g. Flush with water repeatedly in between sample dispensing to minimize any carryover.

7. Handling of Equipment:

   a. Follow the instructions for using equipment.

   b. The diluter's calibration should not be adjusted by laboratory staff as this may invalidate the calibration. If calibration adjustments are necessary, the equipment will be sent out for adjustment and calibration.

8. Routine Maintenance-Monthly Visual Checks: The purpose of the visual inspection is to assess wear or build-up. Visual inspections for leaks need to be conducted by either priming the diluter or while in use. Replacement or cleaning should be made if build-up, wear, or leaks are detected. The monthly check consist of:

   a. Visual inspection of the tubing for leaks and/or build-up.

   b. Visual inspection for leaks and/or build-up around syringes.

   c. The check and any maintenance performed will be documented in the Maintenance Binder.

9. Calibration Checks:

   a. A calibration check will be performed if there is reason to believe the diluter is not functioning as it should.

      i. A gravimetric check should be performed. See below for procedure.
b. Minimally, the check will measure:
   i. Left Syringe (Internal Standard): 1.25mL
   ii. Right Syringe (Samples, Standards, and Controls): 0.250 mL

c. The diluters may also be checked at 1.5 mL, which is total volume (both syringes together) dispensed for forensic alcohol analysis.

d. The mean of six replicates must be within the criteria provided by the external calibration vendor (ie: percent imprecision).

e. Results will be recorded on ALC.19.

f. The check will be maintained in the Alcohol Unit.

E. Pipettes - Variable

   a. Aspirating liquid
      i. The liquid which is to be aspirated is taken from a suitable vessel.
      ii. Attach suitable pipette tip to the pipette firmly.
      iii. Press down the control button to the first stop.
      iv. Immerse the pipette tip vertically approximately 3 mm into the liquid.
      v. Allow the control button to slide back slowly.
      vi. Pull the top out of the liquid slowly.

   b. Dispensing liquid
      i. Hold the tip at an angle against the inside wall of the tube.
      ii. Press down the control button slowly to the first stop and wait until the liquid stops flowing.
      iii. Press down the control button to the second stop (blow-out) until the tip is completely empty.
      iv. Hold down the control button and pull the tip up the inner wall of the tube.
      v. Tip is ejected by pressing the control button to the final stop.

   c. Special Notes
      i. To guarantee the highest degree of precision and accuracy, it is recommended to pre-wet the tip by aspirating and dispensing liquid two to three times before pipetting.
      ii. Make sure to completely empty the liquid from the tip before pipetting (via blow-out).

2. Handling of Equipment:
   a. Follow the instructions for using equipment.
b. The pipettes should be stored to prevent jostling that may invalidate the calibration.

c. The Pipettes should not be adjusted by laboratory staff as this may invalidate the calibration. If adjustments are necessary, the equipment will be sent out for adjustment and calibration.

3. **Calibration Check:**

   a. A calibration check will be performed if there is reason to believe the pipette is not functioning as it should.

   b. The pipette will be checked at the levels checked by the external calibration vendor. The mean of six replicates must be within the criteria provided by the external calibration vendor (ie: percent imprecision).

      i. A gravimetric check should be performed. See below for procedure.

   c. Results will be recorded on ALC.17.

   d. The check will be maintained in the Alcohol Unit.

F. **Gravimetric Check Procedure**

1. The **gravimetric procedure** is done by weighing the amount of water delivered by the apparatus. The mean of six replicates is used to calculate the true volume delivered using the equation below. The temperature of the water is taken to determine the density, see Table I below. The results for each check are recorded on the corresponding instrument check form.

   a. To calculate the volume of water from it's mass: \( V = \frac{W}{d} \)

      i. Where:

      \[
      \begin{align*}
      V & = \text{volume of the water (mL)} \\
      W & = \text{weight of the water (grams)} \\
      d & = \text{density of water (see Table below)}
      \end{align*}
      \]

2. If the results deviate more than the specifications for the equipment, as indicated above, the calibration check has failed. The equipment must be taken out of service. A forensic alcohol supervisor is required to take remedial action to investigate and correct the source of the failure. Calibration may be performed by an external calibration service meeting the requirements of ISO IEC/17025:2005 5.6.2.1.1.

END OF DOCUMENT
I. Policy: All instruments used for alcohol analysis are kept in good working order to ensure their reliability. Below are the procedures that should be followed for the care and maintenance of glassware and thermometers in the Alcohol Unit. (ISO/IEC 17025:2005 5.5.3, 5.5.5.c, 5.5.5.g, 5.5.6, 5.5.8, 5.5.10, 5.6.2.1.1)

A. Thermometers and Volumetric Glassware
   1. A thermometer new to the laboratory will be calibrated by an ISO 17025 compliant vendor before being used in casework. (ISO IEC/17025:2005 5.6.2.1.1, Supplemental 5.6.1.1)
   2. Class A Volumetric Glassware may be used for preparation of solutions prior to calibration. It is suggested that the Volumetric Glassware be calibrated periodically by an external calibration service that is ISO 17025 compliant.
   3. Alcohol or other volatile organic solvents are not used to wash or rinse glassware and instruments used to perform alcohol analysis.

B. Calibration
   1. The thermometers in the Alcohol Unit will be calibrated yearly by an external calibration service that is ISO 17025 compliant. The certificates obtained will contain the measurement results including the measurement uncertainty and/or statement of compliance with an identified metrological specification. (ISO IEC/17025:2005 5.6.2.1.1)
   2. The laboratory will maintain copies of the certificates obtained for at least the current five year accreditation cycle.
   3. The external calibration service labels each thermometer to indicate the calibration status, including the last calibration and the recommendation for the next calibration. (ISO/IEC 17025:2005 5.5.8)

C. Accuracy or Calibration Check (ISO/IEC 17025:2005 5.5.10)
   1. Periodic calibration checks are not required for Class A Glassware or the thermometer
   2. If there is an indication of an issue with the glassware or thermometer than the equipment must be taken out of service; Calibration may be performed by an external calibration service meeting the requirements of ISO IEC/17025:2005 5.6.2.1.1

D. Instructions for Use of Volumetric Flasks (ISO/IEC 17025:2005 5.5.3)
1. Volumetric flasks are generally graduated "to contain" (TC) known volumes of solutions and should never be used "to deliver" (TD) known volumes unless they have been so calibrated. Volumetric flasks are used to make up solutions to a given volume.

2. **Safety**: Volumetric flasks are fragile, and when shaken, should be held at both the neck and bottom. A flask should never be shaken when held at the neck only. When inserting a stopper, hold at the neck rather than at the bottom.

3. **Cleanliness**: Use a clean flask. It usually does not have to be dry, but it must be clean.

4. **Diluting to Volume**: Add the solution to be diluted to the flask, and add distilled water or specified diluent to bring to volume. While raising the meniscus to the graduation mark, hold the mark at eye level and add the last few drops from a wash bottle or from a small pipet. Stopper and invert 6 to 12 times to assure homogeneity. Care should be taken when making the initial inversion, loss of the solution may result if the stopper is not held firmly in place.

5. **Reading the Meniscus**: In the use of graduated cylinders, pipets, burets, and flasks, the lowest point of the meniscus should be taken as the reading. See below.

6. **Handling of Equipment**: Follow the instructions for use. The equipment will be handled in such a way to safeguard the equipment from adjustments that may invalidate test results. (ISO/IEC 17025:2005 5.5.12)

E. **Instructions for Use of Digital Thermometer (Traceable VWR)** (ISO/IEC 17025:2005 5.5.3)

1. Plug the probe into the receptacle located on the right side of the unit
2. Press the ON/OFF key to turn the unit on.
3. Press the °F/°C key to change the display to Fahrenheit or Celsius.
4. Press the .0/.00/.000 key to change the display to read the desired resolution.
5. Turn the ON/OFF key to the "OFF" position when the thermometer is not in use to prolong battery life.

6. Use the probe to monitor temperatures in air/gas, liquids, and semi-solids.

7. Place the stainless-steel portion of probe in contact with the material to be measured.

8. In most instances the depth of the probe needs to be approximately 1/2 inch.

9. **Handling of Equipment**: Follow the instructions for use. The thermometer should not be adjusted by laboratory staff as this may invalidate the calibration. If adjustments are necessary, the equipment will be sent out for adjustment and calibration. *(ISO/IEC 17025:2005 5.5.12)*

END OF DOCUMENT
I. Policy: All instruments used for alcohol analysis are kept in good working order to ensure their reliability. Below are the procedures that should be followed for the care and maintenance of balances and reference standards (check weights) in the Alcohol Unit.

A. New or Serviced Balances
   1. A balance new to the laboratory, or a balance that has been serviced or has undergone substantial maintenance, will be calibrated by an ISO 17025 compliant vendor before being used in casework.

B. Annual Calibration
   1. The balance in the Alcohol Unit will be calibrated yearly by an external calibration service that is ANAB ISO/IEC 17025 compliant. The certificates obtained will contain the measurement results including the measurement uncertainty and/or statement of compliance with an identified metrological specification.
   2. The laboratory will maintain copies of the certificates obtained for at least the current five year accreditation cycle.
   3. The external calibration service labels each balance to indicate the calibration status, including the last calibration and the recommendation for the next calibration.
   4. The balance should not be adjusted by laboratory staff as this may invalidate the calibration. If adjustments and calibrations are necessary, they are performed by an external calibration laboratory either on-site or off-site.
   5. The specifications for calibrations are determined by the external calibration laboratory and meet the guidelines of euramet cg-18 and ASTME 898.

C. Accuracy or Calibration Check
   1. The balance in the Alcohol Unit will be checked monthly to ensure that it is operating satisfactorily. This procedure shall be performed by authorized staff.
   2. Calibration or accuracy checks must be done with reference standards that are NIST (National Institute of Standards and Technology) traceable or American Society for Testing and Materials (ASTM) - ASTM 1 or ASTM 2 weights.
   3. The results of the check will be logged. During the monthly check, the balance should also be checked for cleanliness and to ensure that it is level. The check should be logged in the Balance Calibration Check Log.
4. **Procedure for checking the calibration of the balances in the Drug, Alcohol and Toxicology Section.**
   a. Turn the balance on
   b. Ensure that the balance is level
   c. Tare the balance to a zero weight (0.000)
   d. Place the weight (M1) on the center of the balance. (See Table 1 for the reference standard M1 as appropriate for each balance).
   e. Record the weight result in the Balance Calibration Log
   f. Remove the reference standard (M1)
   g. Tare the balance to a zero weight (0.000)
   h. Repeat with the reference standard M2. (See Table 1 for the reference standard M2 as appropriate for each balance).
   i. Record the weight result in the Balance Calibration Log
   j. Remove the weight (M2)

5. Refer to Table 1 for the allowable error range

6. If the balance falls outside the acceptable range the balance must be taken out of service. Calibration may be performed by an external calibration service meeting the requirements of ANAB ISO/IEC 17025.

7. The following references were used during the development of this procedure:

D. **Instructions for weighing on the balance.**
   1. Place the weighing media near the center of the scale. Tare the weighing media.
   2. Remove weigh boat weighing media and place item in weighing media.
   3. Place weighing media on scale, near center.
   4. Close the draft cover, if applicable.
   5. Weigh item. Allow enough time for balance to settle. If the balance will not settle (more than 10 seconds and still fluctuates) use the lowest weight.
   6. Record the weight.

E. **Handling of Equipment:** Follow the instructions for using the equipment.

1. The balance should not be adjusted by laboratory staff as this may invalidate the calibration. If adjustments and calibrations are necessary, they are performed by an external calibration laboratory either on-site or off-site. The specifications for calibrations have been determined by the external calibration laboratory and meet the guidelines of euramet cg-18 and ASTME 898.

F. Reference Standards

1. The reference standards, check weights, will be checked yearly by an external calibration service that is ISO 17025 compliant. The certificates obtained will contain the measurement results including the measurement uncertainty and/or statement of compliance with an identified metrological specification. See [FSD.28](#) and [FSD.30](#).

   a. The Drug unit will evaluate the certificates and report correction factors to the UOM committee for evaluation.

2. The laboratory will maintain copies of the certificates obtained for not less than the current five year accreditation cycle.

3. All reference standards will be stored, handled, used and transported in a manner that prevents contamination, deterioration and protects the integrity of the reference standard. This includes:

   a. **Storing** reference standards in the packaging provided by the manufacturer to prevent deterioration.

   b. **Handling** reference standards, when practical, with the tweezers provided to minimize deterioration.

   c. **Using** reference standards for their intended purpose i.e. balance calibration checks.

      i. If a reference standard is dropped, it will be sent out for calibration.

   d. **Transporting** reference standards in the packaging provided by the manufacturer to prevent deterioration. Transporting reference standards may
be necessary when weights are transported to/from the external calibration laboratory.

END OF DOCUMENT
I. Policy: The following is the policy for controlling software, tracking the version of software in use in the Alcohol Unit and ensuring the integrity and accuracy of data generated and electronically maintained.

A. Software.

1. Records shall be maintained of the identity of software (version or equivalent) significant to the result and shall, when possible, be uniquely identified. This will be tracked on the Software Log for each piece of equipment. See BA.21

2. Manufacturer's technical support personnel, technical personnel contracted by the Laboratory, technical services personnel and approved lab staff may make changes, additions or upgrades to software. The approval by the Manager or Supervisor in the Software log will be documentation of the Laboratory staff designation to do so.

3. Commercial off-the-shelf software used within its designed application range will be considered to be sufficiently validated. However the tracking of the identity and approval is required.
   
   a. The control or approval for use should be documented in the maintenance log by the Manager or Supervisor.

   b. Any version of Microsoft Word, Excel or Access, Adobe Reader, Adobe Pro, PDFcreator, or JusticeTrax Batch Image Capture is considered to be approved for use.

4. If the software is "custom" or developed by the user, then documentation of validation or verification is required. The tracking of the identity and approval is required.

5. The control or approval for use should be documented in the Software Log in the maintenance binder by the Manager or Supervisor.

B. The Alcohol Unit has a Traceability Database that is an MS Access database program created and maintained by laboratory staff. The purpose of the Traceability Database is to maintain records regarding all equipment used within the unit. Information from reference materials to glassware and instruments used to analyze samples for ethanol content. For more information on the Traceability Database see BA.44 Alcohol Tracking Database which includes operation, functionality, instructions for use, data entry, and backing up data.
1. The verification of the Alcohol Traceability Worksheet that is included in the notes of each blood alcohol report has been completed for the calculation of the quality control ranges within +/-5% of the target.

2. Changes to the alcohol tracking database are kept in a log for the database by laboratory staff.

C. The Alcohol Unit has developed proprietary software known as the Perkin Elmer Blood Alcohol Report System. It consists of a few programs that work in tandem with the Perkin Elmer TotalChrom Navigator instrument software. The instructions for use of this software in analyzing casework can be found in BA.30. The following programs make up the Perkin Elmer Blood Alcohol Reporting System created by Blaise Software, Inc.:

1. Make TotalChrom Sequence (MTCS) - creates a sequence containing the necessary standards, controls, blanks, resolution solutions, and unknowns in the proper order to be analyzed by the reporting software. The unknown information such as the laboratory number, request number, sample type, and request barcodes come from an exported text file from Justice Trax LIMS software to be incorporated into the MTCS sequence that is created.

2. Summary Report - creates a summary report that displays the results of the entire run including the chromatograms of standards, controls, blanks, resolution solutions, and unknown results in a concise manner for review by the analyst and technical reviewer.

3. Sample Report - creates a forensic alcohol report that displays an abbreviated summary of the standards, controls, blanks, resolution solution results and the chromatograms of the unknowns analyzed.

4. The unknowns' results data is transferred via a text file known as the PE12EXP.txt or PE22EXP.txt that is created containing results data to be imported by Justice Trax LIMS software into each laboratory number that was analyzed.

5. The functionality of each component of this software was validated and any changes made to the software are documented and kept within the laboratory Software Verification Binder.

6. The software and all raw data and results are backed-up at least weekly on an external hard drive.

D. The Alcohol Unit will validate crystal templates used as final LIMS Case Reports and Notes which involve calculations and data transfers.

1. The following is the procedure for LIMS generated report and note validation:
   a. Any relevant changes in the Technical Unit Manual and any other related procedures need to be updated prior to implementing the changes in the LIMS crystal reports.
   b. Ensure that all outstanding reports have been Administratively Reviewed.
   c. LIMS administrator can now make necessary changes.
   d. Log off and back on to LIMS to ensure that the updated crystal reports are loaded into LIMS at your workstation.
   e. There are two Laboratory numbers that have been created for the verification of Alcohol Reports, Lab # 12-2375 and Lab # 12-2382
i. Lab # 12-2382 the Coroner's Office has to set as the primary agency
   1. Go to the Agency tab
   2. Right click the Agency "Coroner's Office" and choose "Edit Agency"
   3. Check the box as the "Primary Agency"

ii. Print the report and notes for all of the requests associated with these two Lab numbers.

f. Open the Excel spreadsheet "LIMS Report Validation" located at L:\Lab\Muir\Alcohol\LIMS Report Verifications.
   i. Update the UOM values in the spreadsheet.

g. Compare the values in the spreadsheets with what has been printed in the LIMS reports and notes.

h. Rounding Procedures are as follows:
   i. The "analytical result" is truncated after the fourth decimal from the PE instrument and imported into LIMS
   ii. The "report result" is truncated after the third decimal
   iii. The "uncertainty reported" is rounded up using the GUM rounding method. (e.g. 0.024105 is rounded to three decimals as 0.025; 0.0052080 is rounded to four decimals as 0.0052)
   iv. The uncertainty will be reported with two significant figures.

i. After reports and notes have been printed and verified, go back to Lab # 12-2382.
   i. Go to Agency tab
   ii. Right click agency "Coroner's Office" and choose "Edit Agency"
   iii. Uncheck the box as the "Primary Agency"

j. Open the Word document titled "LIMS Report Verification..." located at L:\Lab\Muir\Alcohol\LIMS Report Verifications.
   i. Update the applicable changes.

k. Save both the Excel and Word documents at L:\Lab\Muir\Alcohol\LIMS Report Verifications.

l. Ask the LIMS administrator to document (ie. e-mail) the changes made in the LIMS report and note templates. Print out document.

m. Submit the following documents to the Supervisor or Manager for review:
   i. Excel Spreadsheets
   ii. Word Document
   iii. LIMS administrator document
iv. Printed or electronic copies of the reports and notes for all of the requests associated with the two laboratory numbers

n. Make a new entry in the "Alcohol Verification Log Binder for Software/Forms" for both of the reports and notes templates.
   i. The entry should be signed off by a Supervisor or Manager.

END OF DOCUMENT
I. Policy: The following procedures will be followed for the quantitative determination of ethanol in biological samples.

A. The instruments are prepared for analysis according to the settings as follows for the blood alcohol methods: BAC1.MTH (DCPE1) or BAC2.MTH (DCPE2)

1. If there is a problem with the power or electrical supply of the instruments performing the analyses due to environmental conditions, instrument power supplies, or power outages, the problem will be remedied prior to beginning the analysis of samples.
   a. Course of action will be dependent upon when disruption occurs.
   b. Staff will evaluate how analysis will be continued.

2. The blood alcohol method parameters are as follows:

<table>

### Gas Flows

**Flame Ionization Detector**

- **Hydrogen** ~45 mL/min.
- **Medical Air** ~450 mL/min.

**Column Carrier Gas**

- **Helium** ~30 mL/min.

---

B. Flame Ionization Detectors for both DCPE1 and DCPE2 are as follows:

1. The instrument automatically loads the TotalChrom method (BAC1.mth or BAC2.mth), however the default setting for the Flame Ionization Detectors for both DCPE1 and DCPE2 is "off".

2. Check that valves are on for the Hydrogen and Air before running the sequence.

3. The FID detector on both columns will be ignited manually by pressing the "IGNITE" button (flame icon on GC Panel) once the method has loaded on the Gas Chromatograph for columns A & B.

4. The gas flows are regulated internally by the Gas Chromatograph and the method.

5. Preferably, this process takes place 20 minutes prior to the start of the run.

---

C. Analysis of Samples and Sampling Procedure

1. Select one vial of blood for analysis after opening and documenting the evidence per General Evidence Handling and Technical Records procedures.

2. Homogeneity is assumed among multiple vials within an envelope or kit as long as the vials were collected sequentially, from a single event, and into multiple similar containers, and having similar volumes. The reported results pertain to the entire item (all vials), not just the tested amount or the vial analyzed.

3. The following sampling procedure will be typically used for alcohol analysis.
   a. Select the vial with the largest volume of blood for alcohol analysis.
   b. Mark the vial to be analyzed with a colored sticker to indicate which of the multiple vials was tested.
c. Inspect the vials of blood for any visible clotting or discoloration. The analyst should note any clotting or discoloration.

d. Bring the samples to room temperature before analysis.

e. Gently mix the blood vial to be analyzed before pipetting. This mixing assures homogeneity within the sample. Typically samples are mixed for a minimum of 20 minutes.

f. A sample sequence is created. See section E. Create an Analysis Sequence below.

g. Open the blood vial to be analyzed by breaking the seal and removing the stopper, and aspirate a portion of the sample into a labeled headspace vial.

h. Using an approved autodiluter, dispense case samples in duplicate, 0.250 mL of sample and 1.250 mL of internal standard into the labeled headspace vial (see BA.26).

i. Cycle the dilutor with de-ionized water to ensure that no bubbles are present in the tubing or pump syringe before preparing a set of samples.

ii. Continue to check for bubbles in the dispenser tubing while dispensing samples.

iii. Wipe the dilutor hand probe and flush it at least three times between each different case sample.

i. The analyst may homogenize samples that cannot be pipetted because of clotting as follows:

   i. Pour entire blood sample from one vial into homogenizer.

   ii. Insert homogenizer plunger through sample in tube.

   iii. Aspirate the portions of blood to be analyzed

   iv. Pour entire homogenized sample back into original blood vial.

   v. Document in the Laboratory Examination Notes if sample has been homogenized.

j. Dispense TWO aliquots of the subject's blood.

k. Stopper each headspace vial after addition of the sample; all vials are crimped prior to analysis.

l. Stopper the blood vial after the aliquots are removed.

4. Labeling and Dispensing

   a. There are two forms an analyst may utilize to ensure samples are in the same order as the sequence.

      i. The LIMS generated "Dispensing Tray Map" (Alcohol Worklist Tray): This is a visual map of the headspace vial trays. This form is optional.

      ii. The Blood Alcohol Gas Chromatograph Worksheet: This is a checklist with corresponding vial numbers and sample names to be dispensed in the proper order.

   b. The analyst will mark each injection headspace vial with the autosampler position number (e.g. 1, 2, 3,...) and with the sample identification (lab number, QC, RS, etc.). After dispensing the samples, place the crimped, labeled vials into the corresponding slot in the headspace autosampler tray.
c. The analyst will utilize the checkboxes on either the Blood Alcohol Gas Chromatography Worksheet or the "Dispensing Tray Map" when dispensing samples.

d. The analyst will utilize the checkboxes in the Blood Alcohol Gas Chromatography Worksheet when placing the vials into the head space autosampler.

5. The analysis is performed by running the sequence with corresponding Sample Set Identification number in the Perkin Elmer Blood Alcohol Reporting System program. See BA.10 for an example of the Blood Alcohol Gas Chromatography Worksheet and the Perkin Elmer Blood Alcohol Reporting System Sequence.

6. The Perkin Elmer GC and headspace autosampler instruments are controlled by two software programs. The TotalChrom Navigator software communicates with both GC and Headspace units and the TurboMatrix software only controls the headspace autosampler. Both applications must be open on the computer which controls the instruments to be run.

D. How to edit ALL solution names within the sequence (prior to creating a sequence).

1. Click on the desktop icon named MakeTCSequence Shortcut. (BE CAREFUL WHEN EDITING THIS FILE. IT IS A .INI FILE THAT HOLDS ALL SETTINGS/CONTROLS FOR THE ANALYSIS.

2. Within the new text window find the section named [IDs] (6th paragraph from the top).

3. Review and correct the lot number names of the five level Standards, Quality Controls, and Resolution Solution with the current solution names to be utilized within your sequence. (ONLY EDIT THE SOLUTION LOTS: Standards, QC's, and Resolution Solution).

4. Save the edits made and exit the program.

E. Create an Analysis Sequence (Automatic Entry from LIMS):

1. The following directions are for the analysis of samples which were downloaded from LIMS to the Perkin Elmer Blood Alcohol Reporting System computers.

2. A sequence will include the following:
   a. Five different NTRM Alcohol Standards at the Concentrations of 0.020%, 0.050%, 0.150%, 0.300%, 0.500%. (These are fixed concentrations)
   b. Blank (distilled or de-ionized water).
   c. Resolution Check Solution.
   d. Water-Ethanol Quality Control reference solution (Beginning of sequence). This is the Title 17 compliant Quality Control.
   e. Up to 40 subject samples, each analyzed in duplicate.
   f. Optional: Blood-Ethanol (Matrix) Quality Control Reference Solution, in duplicate, may be periodically included in the run. See BA.15
   g. Ethanol Quality Control reference solution will be run in duplicate after each set of 10 duplicate subject samples. This can be any Quality Control including: Blood Matrix QC, NTRM vendor purchased QC, or Title 17 QC.
   h. Water-Ethanol Quality Control reference solution (End of sequence). This is the Title 17 compliant Quality Control.
   i. An empty vial to allow the Cleanup-Shutdown method for column conditioning maintenance.
3. On the TotalChrom Navigator Menu choose "Apps", and then choose the application "MakeTCSequence".

4. When the window pops open, press the icon "Select" next to the "Justice Trax LIMS Import File" field.

5. Choose the correct text file generated by LIMS (correlating barcode from the Analytical Worklist) found in the pathway C:\PE1\ or C:\PE2 depending upon which instrument is being used. Folders C:\PE1\ or C:\PE2 are networked on both computers controlling DCPE1 and DCPE2.

   a. If the worklist needs to be sent to the other instrument or changes were made to the worklist, then create a new worklist and send the new one to the instrument.

6. Choose the Analyst's name from the pull down menu. The name formatting should use the first name initial and the first four letters of the last name. (ex: JSMIT for John Smith).

7. Choose the correct instrument name on which the sequence will be run (i.e. DCPE1 or DCPE2).

8. The analyst can add a comment for any sample by clicking the empty box in the "Comments" column in the appropriate lab number row (LIMS Identification).

9. In sequence runs containing more than ten unknown samples, the analyst must choose the appropriate quality controls from the pull-down box. There can be up to three quality controls chosen within a sequence, not including the Title 17 quality control. This is automatically placed at the beginning and end of the sequence.

10. Click on the icon named "Print Worksheet" and a "BLOOD ALCOHOL GAS CHROMATOGRAPHY WORKSHEET" will be printed as a .TIF file and placed in the location C:\PE1(or PE2)\IMAGING\ folder. Go to this folder and print a hard copy of the Worksheet. The printed Worksheet will serve as a checklist when dispensing the samples in the order to be run.

   a. Following the entry of a set of samples into the Perkin Elmer Blood Alcohol Reporting System program, a Blood Alcohol Gas Chromatography Worksheet is generated with a unique Sample Set Identification number assigned according to the date it was created (i.e., yymmddA). The letter after the date corresponds to the number of sample sets created on that date (i.e., A is the first set created, B and C would be the second and third set created respectively). See Below.

11. Create the sequence by pressing the icon labeled "Create Sequence" at the bottom of the window and exit the application.

12. Click YES on the window that pops open that discusses how we must confirm the overwriting function. Exit the MakeTCSequence window.

F. **How to Create an Analysis Sequence (Manual Entry):**

1. This procedure takes the place of a sequence text file being automatically created by LIMS and can be used in the same manner to be imported into the TotalChrom Navigator software when creating a sequence to be run using the method.

2. If the sequence is inputted manually, the analyst may use the LIMS Dispensing Tray Map to facilitate the input of the information into the Perkin Elmer Blood Alcohol Reporting System.

3. Open TotalChrom Navigator program by double-clicking the icon "TCNAV" (If software is not open already on desktop computer).

4. Open the TurboMatrix program by double-clicking the icon "TMatrix" (If software is not open already on desktop computer).
5. Connect the TurboMatrix 110 Headspace instrument to the computer by clicking on the "HS" Tab in the TurboMatrix software window and then choose "Instrument", "Connect" in the top menu (If instrument is not connected already to desktop computer).

6. Open the text file named "Manual Sequence" (located on the desktop in the Folder called "Manual Sequence") to input the samples to be run.

7. The Manual Sequence will have a sample line of information in the proper format. Copy and paste the sample line for the same number of samples to be run in the sequence to be created. For example, this means there should be five lines for five samples, duplicate lines are not needed for duplicate analyses.

8. Replace the sample information with the correct names or laboratory numbers to be run. Do not include any standards or blanks. Only include unknown samples in the order to be run. The vital fields to enter are the "Sample Name" or "Lab Number" and the "Sample Type". Make sure the proper formatting remains in tact with quotes and commas. There should be five sets of quotes, each separated by a comma and an "ENTER" at the end of each line. Blank information within quotes is acceptable in all fields accept the "Sample Name" or "Lab Number". The following format is acceptable per line for each sample:

   a. "SAMPLE NAME OR LAB #","SUBMISSION #","BARCODE 1","BARCODE 2","SAMPLE TYPE"

9. Once the sequence is created with the proper number of entries, choose "File", then "Save As...". Choose the correct pathway C:\PE1 or C:\PE2 and name the text file with the correct date to be run. (Ex: 080129; Format: YYMMDD)

10. Follow the instructions "How to Create an Analysis Sequence (Automatic Entry from LIMS)" to continue the sequence creation by using the YYMMDD text file just created.

G. Running a Sequence:

1. The Status of the GC and Headspace units can be checked by reading within the window of the TotalChrom Navigator software.

   a. A red colored font indicates no method is set-up.

   b. Make sure the TotalChrom Navigator is not set-up with a previous method. Do this by clicking on the "RUN" icon and checking to see the "Clear Setup..." is grayed out or bold.

      i. If "Clear Setup..." is bold click Clear Setup.

2. When TotalChrom Navigator setup is cleared, press the icon Instrument "Setup" and the window titled "Setup Instrument" will pop open.

3. Choose the new sequence created by pressing the folder icon next to the "Sequence" line and choosing the folder with the title containing the date the sequence was created (ex: 080117 for January 17, 2008). The sequence will be within the folder and named with the same date and will have a letter at the end of the title (ex: 080117A.SEQ). Click SELECT.

4. Choose the same folder location for the "Raw File Path" and "Result File Path" data to be saved.

5. Unselect the "Single run data buffering" to avoid adding to the amount of GC run time for each sample injected.

6. Click "OK".

7. The instrument will load the sequence and methods to the Headspace and GC units. While the instruments are setting up, check the manual carrier gas pressure on the Headspace unit panel under the Status Tab. If necessary, set the value to 30.0 psi. by turning the manual
control knob on TurboMatrix 110 Headspace unit. Increase or decrease the pressure setting from the manual control knob. Let the pressure stabilize to 30.0 psi.

8. Once the method is loaded, the Air and Hydrogen valves will be opened and the gas flows will be displayed on the PE Clarus 580 GC touch sensitive panel. Check to make sure the ACTUAL pressures are close to the SET values. If the pressures are at the set point on the GC touch sensitive panel, press the "IGNITE" icon to light the FID (Flame Ionization Detector) for Column A.

9. Choose Column B in the upper tab on the screen, and "Ignite" the flame for Column B as well. Both Column A and B must be lit to collect data from each column. It is best to light both detector flames at least 20 minutes prior to starting the run in order to equilibrate the signal on each detector.

10. After dispensing the samples, place the headspace vials into the headspace unit's magazine in the proper numerical order by following the "BLOOD ALCOHOL GAS CHROMATOGRAPHY WORKSHEET".

11. Place a second check mark on the "BLOOD ALCOHOL GAS CHROMATOGRAPHY WORKSHEET" when each vial is loaded on the headspace autosampler.

12. Once the samples are correctly placed in the autosampler magazine and the status reads "GC: Ready" on the TotalChrom Navigator window, start the run by pressing the "RUN" icon and choose the "Start Run" option.

H. How to process and print out the Analysis Results (Forensic Alcohol Summary Report and Forensic Alcohol Reports):

1. Once the entire analytical sequence has completed, the sample results can be calculated and printed. This function is performed by clicking on the "Publish" icon in the TOTALCHROM Navigator window. A new window will pop open titled "TC Publisher Report Console". This window contains the settings to choose the proper folder which contains the current data to process and print.

2. Choose the appropriate sequence file by clicking on the "Report Options" icon thereby opening a new window titled "TC Publisher Report Options". In the "Data" Field you can enter the proper folder by clicking on the "..." icon. Choose the proper data folder and "*.idx" file (i.e. 150803A.idx) which is labeled with the same title as the sequence listed on the Blood Alcohol Gas Chromatography Worksheet previously created. (ex: Data path: C:\GC2\Data\150803A\150803A.idx for the sequence 150803A.seq).

3. In the "Report" Field enter the first report to process a daily sample run by clicking on the "..." icon. Choose the correct report format labeled "CCCSD-SUMMARY-38.tpm" (ex: Data path: C:\PenExe\TcWS\Ver6.3.2\CCCSD-Summary-38.tpm).
   a. Be sure the pathway is highlighted before clicking "...". Otherwise, it will add a report instead of replacing a report.
   b. Leave the Output settings as is. Click OK.

4. If a preview is desired for viewing on the monitor before running the report, press the "Preview Report" icon. This function performs all of the necessary data processing by calibrating the method with the new data, but does not automatically print out the reports.

5. To print out the results, press the "Run Report" icon. This function performs all of the necessary data processing, updates the calibration of the method stored and displays the "Forensic Alcohol Summary Report". Print the "Forensic Alcohol Summary Report" to PDF Format and save in run data folder.

6. Check to make sure only one entry is recorded into the "Data" and "Report" fields in the "TC Publisher Report Console" window.
7. Click on the "Report Options" icon again and in the "Report" field enter the next report by clicking on the "..." icon. Choose the report "CCCSD-Sample-48.tpm" (ex: Data path: C:\PenExe\TeWS\Ver6.3.2\CCCSD-Sample-48.tpm).
   a. Be sure the pathway is highlighted before clicking "...". Otherwise, it will add a report instead of replacing a report.
   b. Leave the Output settings as is. Click OK.

8. Preview the report for viewing on the monitor by pressing the "Preview Report" icon. This function performs all of the necessary data processing, by calibrating the method with the new data but does not automatically create the images to be sent to LIMS. A PDF copy can be printed, if desired.

9. When ready to send the sample chromatogram images to LIMS, press the "Run Report" icon. Remember to delete ALL files in the folder C:\PE1(or PE2)\IMAGING before clicking on "Run Report". "Run Report" performs all of the necessary data processing, updates the calibration of the method stored, and saves the individual "Forensic Alcohol Report" (s) as .TIF files for each sample analyzed in the folder C:\PE1(or PE2)\IMAGING. See BA.43 for more Instructions for Imaging in LIMS.

10. Click on the "Report Options" icon again and in the "Report" field enter the last report by clicking on the "..." icon. Choose the report "CCCSD-LIMS-Export-11.tpm" (ex: Data path: C:\PenExe\TeWS\Ver6.3.2\CCCSD-LIMS-Export-11.tpm).

11. Press the "Run Report" icon. This function performs all of the necessary data processing, updates the calibration of the method stored and displays the individual results to the PE12Exp.txt or PE22Exp.txt file to be imported by LIMS. This .TXT file will be printed to the C:\PE1 or PE2 folder. Copy the PE12Exp.txt or PE22Exp.txt file to the run data folder.

12. After printing all three reports, navigate to the folder C:\PE1(or PE2)\IMAGING and delete all files except the .TXT and .TIF files that contain PE(1 or 2)_TcPub CCCSD-Sample-480000XX.TXT or similarly named .TIF files with the time/date stamp that correspond to your run. The other files are printed because the JusticeTrax Imaging driver is active but these files are not needed. When JusticeTrax Batch Indexer imports files, it acquires all files within the folder including the unnecessary files if not deleted.

13. See BA.43 for procedures on how to import the individual "Forensic Alcohol Report" images to LIMS.

14. Print Calibration Plots for each column. Using the TOTALCHROM Navigator window click on the "Build Method" icon.
   a. Choose "Load recently edited method"
   b. Load the data path that corresponds with either column A or B
      i. C:\GC\Methods\BACa.mth (or BACb.mth)
      ii. click OK. The Method Editor window will be displayed.
   c. Click on "Other" from the menu, then choose "Fit Analysis (CalPlot)."
      i. Navigate to the Ethanol plot by clicking on the icon of a graph with a right arrow to advance through the other analytes.
         1. Click "ok" to the Acetaldehyde error message that pops-up.
      d. Choose "Display" from the menu, then choose "Labels."
i. uncheck the box for "Automatically assign default labels" to correctly label
   the CalPlot

   1. Plot Title: Ethanol CalPlot A (or B)
   2. X-Axis label: Ethanol STD Concentration
   3. Y-Axis label: Ethanol/ISTD Area Ratio

   1. Click OK to display the CalPlot with the updated labels.

e. To print the CalPlots for the run packet, choose "File" from the menu, then chose
   "Print."

   i. Uncheck the "Calibration Data" box.

   1. The CalPlot should display the R-squared value, the linear equation,
      and the plot.

1. **Calculations:**

   1. Calculations are performed automatically by the laboratory data system according to the
      equations below.

   2. The linear equation is determined by calibration with the duplicate analysis of the five
      NTRM alcohol standards. These concentrations fall within the linear range of the
      instrument's calibration curve established during the validation of the method (See BA.20).
      The linear equation is used to calculate the concentration of ethanol in the unknown
      sample by the following equation: \( Y = MX + B \)

      a. **Y** = ratio peak area of Ethanol to peak area of n-Propanol

      b. **X** = concentration of Ethanol

      c. **M** = slope of the line

      d. **B** = intercept

   3. The unknown sample concentration can be calculated using modified equation: \( X = (Y - B)/M \)

      a. **Unknown Conc.** = [(Ethanol Response/n-Propanol Response) – intercept]/slope

      b. Therefore, when substituting the responses into the equation the exact concentration
         of the internal standard n-propanol need not be determined as it is used in the
         calibration as well as the calculation and the numerical value cancels out.

   4. The analytical results (concentration of ethanol in unknown sample) for each of the
      samples will be transferred from the Blood Alcohol reporting software (TotalChrom) to
      JusticeTrax LIMS. LIMS will assign uncertainty to the analytical result based on the
      concentration (see Uncertainty).

   5. For blood samples, LIMS will average the analytical results and truncate to three-digits for
      a reported value that is compliant with Title 17 requirements.

   **Sample calculation:** **Unknown Blood Sample with equation:** \( Y = 59.768872X + \)
(-0.091140); 

Ethanol Response 219907.27 
n-Propanol Response 25278.48 

Y-intercept -0.091140 
Slope 59.768872 

a. Unknown Conc. = [(Ethanol Response/n-Propanol Response) – intercept]/slope 
or Conc = [(219907.27/25278.48) - (-0.0911400000)]/ 59.768872000 

b. Blood Alcohol Concentration = 0.1470 % (W/V) 
c. Reported value = 0.147 % (W/V) 

6. For urine samples, LIMS will average the analytical results, then divide the average result by 1.3, and truncate to three-digits for a reported value that is compliant with Title 17 requirements.

Sample calculation: Urine 

Ethanol Response 219907.27 
n-Propanol Response 25278.48 

Y-intercept -0.091140 
Slope 59.768872 

a. Unknown Conc. = [(Ethanol Response/n-Propanol Response) – intercept]/slope 
or Conc = [(219907.27/25278.48) - (-0.0911400000)]/ 59.768872000 

b. Conc. = 0.147075 

c. Therefore, if the average concentration for four results is 0.147845, then divide by 1.3 = 0.113726 

d. Converted Alcohol Concentration = 0.1137% (W/V) Blood Alcohol 

e. Reported value = 0.113% (W/V) Blood Alcohol 

7. For vitreous samples, LIMS will average the analytical results, then divide the average result by 1.27, and truncate to three-digits for a reported value.

Sample calculation: Vitreous 

Ethanol Response 219907.27 
n-Propanol Response 25278.48 

Y-intercept -0.091140 
Slope 59.768872
a. **Unknown Conc.** = \[(\text{Ethanol Response/n-Propanol Response}) – \text{intercept}] / \text{slope}

or Conc. = \[(219907.27/25278.48) - (-0.091140000)] / 59.768872000

b. Conc. = 0.147075

c. Therefore, if the average concentration for four samples is 0.147938, then divide by 1.27 = 0.116486

d. **Converted Alcohol Concentration** = 0.1164% (W/V) Blood Alcohol

e. **Reported value** = 0.116% (W/V) Blood Alcohol

J. **Performance Standards and Remedial Actions:**

1. The following criteria must be fulfilled for known alcohol samples for the results of analyses of a given set of samples to be considered valid and reportable:

   a. The result obtained for the Blank Sample is less than 0.01% (located in the Forensic Alcohol Report created by the Sample Report).

   b. The Calibration Curve shall be linear with an "R^2" value of 0.98 or higher (located in the Forensic Alcohol Report created by the Sample Report).

   c. The results obtained for the Ethanol Quality Controls (located in the Forensic Alcohol Summary Report created by the Summary Report and in the Forensic Alcohol Report created by the Sample Report) are as stated in procedures **BA.15 - Quality Controls**.

   d. The results obtained for the NTRM Standard are within ± 5 % of the reference target concentration (located in the Forensic Alcohol Summary Report created by the Summary Report or in the Forensic Alcohol Report created by the Sample Report).

   e. The compounds in the resolution solution shall indicate baseline resolution for all compounds listed except, on column A, the methanol and acetaldehyde peaks may have near baseline resolution that is allowable. Validation data did not always show baseline resolution in every run (located in the Forensic Alcohol Summary Report created by the Summary Report).

2. The following criteria must be fulfilled for unknown alcohol samples for the results of analyses to be considered valid and reportable:

   a. The results obtained for aliquots of each unknown sample shall be within ± 5% of the mean result (located in the Forensic Alcohol Summary Report created by the Summary Report or in the Forensic Alcohol Report created by the Sample Report).

   b. Unknown sample results with a mean that is below 0.010% will be exempt from the ± 5% of the mean criteria and will be reported as Not Detected (located in the Forensic Alcohol Summary Report created by the Summary Report or in the Forensic Alcohol Report created by the Sample Report).

   c. Acceptable chromatography must be observed in the ethanol and internal standard peaks within each sample's chromatogram as defined by the following:

      i. chromatography peaks that have good separation of compounds within the mixture.

3. If performance standards above are not fulfilled, the results of the analyses of the set will be considered in error and the situation will be reported to a Supervisor or designee for suitable remedial action.
4. No results will be reported until the performance standards above have been fulfilled for each set of samples analyzed.

5. If there is an indication of a problem with the equipment the equipment may be checked in-house or sent to an outside vendor for calibration and/or adjustment as deemed necessary.

K. Inconclusive Results:

1. Inconclusive results may be due to poor chromatography, interfering substances, instrument issues, matrix issues, insufficient sample size, or other reasons.
   a. An interfering substance can be any compound that may have a retention time within +/-3% of the retention time of ethanol or n-propanol on at least one column that may affect the chromatography or quantitation results.

2. Reanalysis or instrument maintenance may resolve the issue.

3. If the issue cannot be resolved, the sample will be reported as inconclusive and the reason will be included on the report. For example: Inconclusive due to ethanol not resolving on both columns due to a possible interfering substance.

4. The sample may be sent to an outside laboratory for additional analysis. See Procedure BA.37 - Outside Laboratory Analysis for instructions.

L. Reporting:

1. See BA.11 and BA.31 for information on how to generate a Laboratory Report of Examination.

2. See BA.39 and BA.40 for more information about reporting the associated estimation of uncertainty for quantitation of ethanol in blood, urine and vitreous samples.

3. Most ante mortem and post mortem results will fall within the Laboratory's reportable linear range (0.02-0.50%).
   a. For results that are above the reportable linear range, the sample will be reported as "greater than" or "above" the upper limit of the reportable linear range or limit of quantitation.
      i. Urine and vitreous samples will be reported as "greater than" or "above" the upper limit of the reportable linear range or limit of quantitation when the un-converted result is above a 0.50%.
   b. For results that are between 0.01% - 0.02%, the results will be reported as "Ethanol is present at a level less than 0.02% W/V".
   c. For Other Volatile Compounds present:
      a. From the information printed on the Summary Report, check the other volatile compounds (Methanol, Acetaldehyde, Isopropanol, & Acetone) that are populated in the Comments column. Any other volatile compound is listed when it is present above the integration cutoff.
      b. When listed on the Summary Report, compare the area counts of the annotated volatile compound in the unknown sample's chromatogram with the area counts of the same volatile compound within the Resolution Solution (RS) chromatogram.
c. If any of the four compounds listed on the Summary Report has an equal or higher area count than that compound in the Resolution Solution, it must be reported. For example, if the unknown sample area count for Acetone is 29321 and the area count for Acetone in the Resolution Solution is 26167, Acetone must be reported. A statement will be placed in the report such as "Detection of Possible Acetone"

d. Make a statement for each volatile compound present above the RS area counts for Methanol, Acetaldehyde, Isopropanol or Acetone.

I. Policy: The following procedure should be used for a quality assurance check of the sodium fluoride content of kits.

A. It is recommended to check new lots of blood and urine kits that are received for sodium fluoride content.

1. These checks are typically performed on at least one vial from two kits per lot of blood kits and two jars per lot of urine kits.

2. The results of these checks should be documented and maintained as a quality assurance check of the vendor that provides the kits. The documentation will be maintained in the Alcohol Unit.

3. **The check will be performed by an outside laboratory.**
   a. The referral laboratory should be consulted to determine if there are any preparation requirements prior to sending the sample.
   b. For example, NMS LABS requires the sample be diluted with water prior to shipment. It is recommended that each of the blood tubes be diluted to 10 milliliters and each of the urine jars be diluted to 2 fluid ounces or ~ 59.2 (29.58 x 2) milliliters quantitatively.
   c. The results for the concentration of fluoride ion should meet the Performance Criteria in this document.

4. More quality assurance information regarding the sodium fluoride content of the kits may be obtained from the vendor

B. Data interpretation

1. The results from the outside laboratory may not be provided in the proper units to determine if the amount of sodium fluoride is present.

2. An analyst must calculate the amount of sodium fluoride present in the samples in each lot from the results provided. This can be done by hand calculation or the use of MS Excel or equivalent software to help convert the results.

3. Use the following conversion formula:
   a. \[ X \text{ mg Fluoride(F)/L} \times \left(1 \text{ mol NaF}/1 \text{ mol F}\right) \times \left(1 \text{ mol F}/18.9984 \text{ g F}\right) \times \left(41.9882 \text{ g NaF}/1 \text{ mol NaF}\right) \times \left(1 \text{ g F}/1000 \text{ mg F}\right) \times \left(1 \text{ L}/1000 \text{ ml}\right) \times \left(100\text{ ml}/100\text{ ml}\right) = Y \text{ g NaF}/100 \text{ ml} \]
b. Ex: Result: Fluoride = 4400 (mg F)/L

i. 4400 mg F/L x (1 mol NaF/1 mol F)x(1 mol F/18.9984 g F)x(41.9882 g NaF/1 mol NaF)x(1 g F/1000 mg F)x(1 L/1000 ml)x(100ml/100ml)=
0.9724 g NaF/100 ml

ii. 0.97 g NaF/100 ml > 0.80 g NaF/100 ml.

iii. Therefore, the sample passes the criteria for Sodium Fluoride content and the lot of blood kits is acceptable for use.

C. Performance Criteria

1. All blood tube samples should have a fluoride ion concentration of at least **0.80 g/100ml**.

2. All urine container samples should have a fluoride ion concentration of at least **0.64 g/100ml**.

3. Blood, urine, and water matrices should not effect the fluoride ion concentration.

END OF DOCUMENT
I. Policy: The Alcohol Unit staff shall comply with all reasonable and legitimate Discovery Requests. 

A. All discovery criminal requests are routed to the Forensic Services Division via the District Attorney's Office. These requests typically pertain to documents related to the analysis of samples or records kept in the normal course of Laboratory business. Please see the Division Manual FSD.45 for more information on discoveries.

B. The Alcohol unit provides "basic discoveries" or "extensive discovery" records.

C. A "basic blood/urine discovery" is a pre-set package that consists of:

1. Copy of laboratory report and notes
2. Summary Report for the run
3. Monthly calibration (only for single column GC-FID analysis - PE1 / PE2)
4. Maintenance Log (to minimally cover six months before and after the date of analysis)
5. Chain of Custody
6. SOQ of analyzing Criminalist

D. An extensive discovery is not a pre-set package. It may be a request for more detailed documentation to include but not limited to the Examination Records, Instrument Records, Equipment used and their Calibration Records, Standard Operating Procedures, Proficiency Records etc.

   1. If the discovery information sought appears to be unreasonable or irrelevant, a Supervisor or designee may contact the District Attorney's office for assistance in obtaining a modification or quashing the discovery. The District Attorney's office should review criminal discoveries for relevance, before sending the request to the laboratory.

E. Discovery Procedures:

1. The Clerical staff will create a discovery request in LIMS and image the request paperwork. CLER.DAT.12
2. The analyst within the unit will review the discovery request and determine if further information is needed.
3. The discovery requests may be completed electronically and posted via ARIES.
   a. The electronic files of the records requested will be gathered and uploaded into LIMS. If concatenation is desired, detailed procedures on how to concatenate .pdf documents can be found in "Electronic Batch Documents". TOX.10
   b. The Notification of Compliance Form is used when discovery records are being provided as a part of a Subpoena Duces Tecum (SDT) or being provided to the Sheriff's Department Records Office.
   c. The Affidavit of Custodian of Records Form will be completed, digitally signed and included in the electronic files.
   d. In the LIMS imaging module, right-click each image to be released as part of the discovery, and select "Send To iResults". A check mark will appear next to the "Send to iResults" menu.
   e. There must be "Findings Entered" before the request can be "Draft Complete." In LIMS, the analyst should:
      i. Right click on the discovery request and choose the result type: Summary
      ii. Add a comment describing what was completed and where it was sent.
      iii. Initial and date.
   f. The discovery request will be marked as "Draft Complete" by the analyst completing the discovery.
   g. The completed discovery will be checked and marked "Admin Reviewed" by another analyst or a Supervisor.
   h. The electronic discovery records will be accessible via ARIES for the District Attorney's office to retrieve. There is a 24 hour lag from the time the case has been Admin Reviewed before the records will be accessible to the DA's office.

4. Any records not amenable to be uploaded into LIMS (e.g. CD or DVD of raw data etc) will be provided outside of ARIES.

5. Any "Rush" discoveries request may need to be provided as paper or faxed copy. The Rush discoveries need to be approved by the Supervisor to assess the exigency of the circumstances FSD.45

F. See Breath Alcohol Technical Unit Manual BRA.15 for detailed information on producing records for breath discoveries.

G. Subpoena Duces Tecum (SDT) for DMV Hearings
   1. The only form accepted as a request for a DMV hearing discovery is the SDT form (DMV Subpoena Duces Tecum) available from the DMV Office or at www.dmv.ca.gov.
   2. Any other requests (informal or letter requests) will be rejected by lab staff and an official DMV SDT will be requested from the law office that submitted the discovery request.
3. A private citizen may request records from the laboratory with the proper SDT form for their own DMV hearing. However, the laboratory will only deliver the records to the DMV hearing office upon a citizen's request.

4. The Alcohol Unit staff will adhere to FSD.45 and CCCSO Policy 1.05.68 in properly completing and SDT
   a. The discovery will be completed and kept electronically in LIMS unless records that are not amenable to being uploaded to LIMS are provided (e.g. CD or DVD containing raw data).
   b. All DMV SDT's should be sent to the address as instructed on the first page of the DMV SDT and may be sent to the requesting attorney's offices upon request.
   c. A copy of each completed SDT discovery request should be forwarded to the CCCSO Records Office with a completed Notice of Compliance form when it is released.
   d. If the initial request for discovery records is unreasonable and overly burdensome, the laboratory will send a basic discovery and notify the requesting attorney and DMV offices of the records sent.
   e. If a second extensive DMV SDT is received by the laboratory, the laboratory will comply to the best of its abilities or notify the requesting attorney why items could not be produced when necessary.

H. See FSD.45 and CLER.DAT.12 for handling of Civil Discoveries and Subpoena Duces Tecum.

END OF DOCUMENT
I. Policy: Occasionally, it is necessary to send samples to laboratories outside the FSD (Forensic Services Division) to perform alcohol analyses. This may occur when the alcohol analysis is requested and the Laboratory cannot perform the analysis (See BA.30 for inconclusive results examples for OLA's) or at the request of the defense (referee analysis).

A. Subcontracting or Outside Laboratory Analysis (OLA):

1. When analysis is requested that the laboratory is unable to perform, the sample may be sent out to a competent outside laboratory for analysis. This may occur due to the laboratory's inability to perform the analysis (i.e. decomposed blood samples, interfering substances, or other volatiles), inadequate staffing levels, or other unforeseen reasons. Samples are typically sent to NMS Labs; however, other competent laboratories may be used once their accreditation has been evaluated.

   a. When an outside laboratory is utilized, the report shall reflect that the sample was sent to an outside laboratory for analysis.

   b. The Crime Lab is responsible for selecting an outside laboratory unless the customer specifically requests that the sample be sent to a laboratory of the their choosing.

   c. A list of competent outside laboratories will be maintained along with documentation of competence.

      i. Compliance with ISO 17025 is considered a demonstration of competence.

      ii. Competence may also be determined by evaluation of accreditations, licensure, participation in proficiency testing programs, and participation in professional organizations.

2. Follow the instructions in TOX.56 (section "C. Procedure for Sending OLA Samples") for performing OLA's.

B. Referee Analysis:

1. Referee samples are those which are taken at the request of the Arrestee to verify the accuracy of the analytical result. The Vehicle Code permits the analysis of these samples by either the prosecution or the defense for use in subsequent proceedings.
2. Upon written request by the defendant's attorney and with authorization from the district attorney's office, submitting police agency, or receipt of a court order, a blood or urine sample will be released to the authorized person, institution, or laboratory.

   a. The laboratory has a long-standing blanket authorization from the DA's Office stating that a written authorization is not required for a referee analysis on CVC 23152 cases.

   b. If available, an unopened blood vial, which has not been examined by the Crime Lab, will be sent for referee analysis.

   c. In some cases, only one vial of blood is collected. If there is sufficient blood to divide, a portion of the original will be removed. The portion of the sample to be forwarded is placed in a new grey top vial (without preservative or anticoagulant) and labeled with the laboratory number, subject's name, the initials of the person preparing the sample, and the date. The vial is then tape sealed, with initials and date. Whenever possible, a portion of the sample should be retained by the laboratory for further or referee analysis, if needed. Samples of less than 3 mL are not considered adequate for "splitting". Therefore, if the sample is less than 3 mL, a court order or written authorization by the prosecuting district attorney must be received to forward the entire remaining original sample.

   d. If the sample for referee analysis is urine, a portion of the original urine sample is transferred to a clean glass vial. Aliquot approximately 5 mL into a small vial with no preservative. The vial will be labeled with the laboratory number, subject's name, the initials of the person preparing the sample, and the date. The vial is then tape sealed, with initials and date. Whenever possible, a portion of the sample should be retained by the laboratory for further or referee analysis, if needed. In rare cases, there is insufficient sample available to divide. If there is insufficient sample available, a court order or written authorization by the prosecuting district attorney must be received to forward the entire remaining original sample.

3. The split sample is then placed into a new Alcohol envelope that is marked "DUPLICATE." All applicable information should be filled out on the duplicate envelope. The person preparing the sample will fill out the chain of custody on the envelope, tape seal the envelope, and then date and initial the seal.

   a. See Forensic Services Division Manual for information to transfer evidence to outside agencies. Please refer to the Division Manual for required documentation on release of evidence for referee analysis or outside laboratory analysis (OLA).

4. All authorizations and receipts shall be retained on file by the laboratory report number.

5. Golden State Overnight (GSO) shipping company is used for example purposes, but any a traceable shipping company may be used.

C. Storage of Referee Samples

1. Referee samples that were not analyzed by the laboratory will be returned immediately to the submitting agency for storage. Sheriff and contract city's referee samples will be forwarded to Sheriff's Property and Evidence Services for storage.
Each agency handles the storage and disposition of samples based on their evidence disposition policies.

2. Referee samples that were analyzed by the Forensic Services Division will be retained for at least one year, the same way other samples examined for driving offenses.

D. Defendant Requests for Reanalysis and Referee Analysis

1. The Forensic Services Division does not perform reanalysis of samples at the request of the defendant for cases that were analyzed by this Division.
   a. The defendant can request the reanalysis by an independent laboratory. The defendant, or the defense attorney, must arrange to have the Forensic Services Division forward the sample to the laboratory of his/her choice.

2. If the laboratory sends a sample out, the Forensic Services Division must have a written request provided by the attorney. A letter from the defendant's attorney, or defendant if representing themselves, a court order, or a copy of a letter to the referee laboratory of choice should state, in essence:
   a. that an alcohol analysis is being requested
   b. the name of the outside laboratory selected
   c. that the analysis is at the defendant's expense
   d. the laboratory number for the sample requested (or other sufficient information such as subject name, agency, agency case number, etc.)
   e. An authorization from the Contra Costa County District Attorney's Office is required for non-DUI cases and felony DUI cases.
   f. A check for sample handling and postage must also be received

E. Procedure for Sending a Referee Sample

1. Fill out an OLA request form and a Billing Sheet. These forms can be found on the Sheriff's Intranet or PowerDMS (ALC.38 and ALC.07).
   a. After the signature on the original referee request letter, the person completing the transfer should write "Done" with his/her initials and the date completed.
   b. The original referee request letter, the check, a copy of the OLA Request Form, and the OLA Billing Sheet are retained on file by the laboratory report number.
   c. A copy of the request letter and a copy of the OLA Request Form are sent to the outside lab with the sample.

2. Obtain the sample from it's storage location, such as the Muir Alcohol Long Term Refrigerators.
   a. Record each transfer in the chain of custody using both the electronic chain and the written chain on the envelope.
   b. Record the following on the chain of custody on the original envelope:
      i. Received From (complete as appropriate):
1. Split (1) grey top vial w/blood analyst's initials
2. Split portion from grey top vial analyst's initials
3. Split portion from urine jar analyst's initials

ii. Received By:
1. Via GSO to other lab (for example BAFL=Bay Area Forensic Laboratory)

iii. date of split

iv. For example:

<table>
<thead>
<tr>
<th>Received From:</th>
<th>Received By:</th>
<th>Date:</th>
</tr>
</thead>
<tbody>
<tr>
<td>EVID</td>
<td>Your name</td>
<td>Date</td>
</tr>
<tr>
<td>Split (1) grey top vial w/ blood your initials</td>
<td>Via GSO</td>
<td>Date</td>
</tr>
<tr>
<td>Your name</td>
<td>EVID</td>
<td>Date</td>
</tr>
</tbody>
</table>

3. Remove the vial (or jar) from the original envelope and add the following information to the vial being sent out:
   a. laboratory case number
   b. your initials
   c. date of the split
   d. subject name

4. Itemize the sample in LIMS, if it has not yet been done.
   a. In the "Evidence" tab, right click on the appropriate item of evidence and select "Itemize Evidence."
   b. In the "Description" section, enter the appropriate description:
      i. Split one grey top vial with blood for referee analysis via GSO to other lab
      ii. One grey top vial with blood split from one grey top vial for referee analysis via GSO to other lab
      iii. One screw top vial with urine split from jar for referee analysis via GSO to other lab
   c. Register an item barcode for the sample being split.
   d. Choose the correct type of sample for "Evidence Type," for example blood for blood evidence.
5. Attach the item barcode to the duplicate envelope, if not already printed.

6. Record the electronic chain of custody for the split item:
   a. From: Analyst
   b. Via: "Split Chain of Custody"
   c. Note: "Via GSO"
   d. To: outside lab

7. Complete the chain of custody on the duplicate envelope as appropriate:
   a. Received From:
      i. Split (1) grey top vial w/blood analyst's initials
      ii. Split portion from grey top vial analyst's initials
      iii. Split portion from urine jar analyst's initial
   b. Received By: Via GSO to other lab (e.g. BAFL=Bay Area Forensic Laboratory).
   c. date of split

8. Seal, initial, and date the duplicate envelope.

9. Initial and date previously opened vial on existing green label.

10. Seal, initial and date the original envelope with the remaining evidence inside.

11. Mailing the sample:
    a. package the sample for safe handling.
    b. schedule a pick up with the shipping company.
    c. evidence waiting to be picked up for shipment should be stored in the Muir Log In Refrigerator.
    d. return the sealed original envelope to it's storage location & record the transfer in LIMS and on the envelope.

12. The following will be given to the clerical staff:
    a. Original request letter with date and initials of the analyst
    b. Documentation of the cost (i.e. Billing Sheet)
    c. A copy of OLA request form
    d. Payment check

F. Procedure for sending entire evidence envelope when the lab has not analyzed the evidence (Trombetta sample)

1. A written request must be provided by the attorney in order for a sample to be sent to another lab for analysis. The request must include the following:
   a. payment for sending out the sample
b. name and address of laboratory that the referee sample is being sent to

c. laboratory number for the sample requested (or other sufficient information such as subject name, agency, agency case number, etc.)

d. District Attorney authorization (if needed)

2. Fill out an OLA request form and Billing Sheet. These forms can be found on the Sheriff's Intranet or PowerDMS (ALC.38 and ALC.07)

3. Obtain the sample from it's storage location.

   a. If the evidence is no longer at the laboratory, a request for the Blood Alcohol Envelope from the agency may need to be made.

4. Record each transfer in the chain of custody using both the electronic chain and the written chain on the envelope.

   a. Complete the chain of custody on the envelope as follows:

      i. Received From: Evid

      ii. Received By: Analyst's name

      iii. Date of transfer

      iv. On a new line, Received From: Analyst's name

      v. Received By: Via GSO to other lab (e.g. BAFL=Bay Area Forensic Laboratory.

      vi. Date of transfer

5. After the signature on the original referee request letter, the person completing the transfer should write "Done" with his/her initials and the date completed.

6. Include both a photocopy of the written request for referee analysis and a copy of the OLA request form with the envelope.

7. Sending the sample, a traceable shipping company should be used, such as GSO:

   a. package the sample for safe handling.

   b. schedule a pick up with the shipping company.

   c. evidence waiting to be picked up for shipment should be stored in the Muir Log In Refrigerator.

   d. record the transfer in LIMS

8. The following will be given to the clerical staff:

   a. Original request letter with date and initials of the analyst

   b. Documentation of the cost (i.e. Billing Sheet)

   c. A copy of OLA request form

   d. Payment check

END OF DOCUMENT
I. Policy: These guidelines in conjunction with the *Forensic Services Division Safety Manual* will be followed to ensure employee safety within the laboratory (Supplemental 5.3.6).

A. Wear appropriate personal protective equipment when handling chemical and bio-hazardous materials. Consult the *Forensic Services Division Safety Manual* for further information. Safety Data Sheets (SDS), located in the laboratory technical units, should be consulted whenever using an unfamiliar chemical.

B. The following personal protection equipment should be worn at all times when working with or near hazardous substances or activities:

1. Laboratory coat
2. Latex or nitrile gloves
3. Safety glasses when mixing and preparing reagents
4. Safety glasses with side shields that conform to the American National Standards Institute (ANSI) standards (prescription glasses with safety lenses and side shields are allowed).
5. No safety glasses are necessary while working within the fume hoods with the sash closed below the adequate ventilation line.

C. It is the responsibility of the analysts working within the lab to be familiar with the Division's Safety Manual and to comply with all safety requirements.

D. When using "Sharps" or "Sharps Biohazard" bins for disposing of glassware or other "sharps", the bin should not be filled past the "fill line" indicated on the bin.

E. All bins need to be labeled appropriately (regardless of any markings on the bags inside the bins). This includes: "Biohazard", "Chemical Waste" and "Debris Waste".

1. Typically, "chemical waste" consists of large amounts of chemicals like:
   a. corrosive acid inorganic waste or "acid waste"
   b. flammable organic waste or "organic waste"
   c. corrosive basic inorganic waste or "basic waste"
2. Typically, hazardous waste solids or "debris waste" contains items with chemical residue (eg. slides, pipettes, spot plates etc).
3. Biohazard waste consists of biohazard materials (eg. blood soaked gloves).
   a. gloves or "wipes" with small amounts of blood may be placed in the trash cans

F. Any larger container (e.g. 50 gallon drum) used to temporarily hold the bags of waste should also be labeled appropriately. This includes: "Biohazard", "Chemical Waste" and "Debris Waste".

END OF DOCUMENT
I. Policy: The Alcohol Unit has assessed estimated uncertainty for analysis of blood, urine and vitreous samples for ethanol content.

A. Quantitation of ethanol in blood and urine are considered to be a measurement that matters as legal enhancements may be charged if certain concentrations are exceeded.

B. The Alcohol Unit has attempted to identify all components of uncertainty associated with quantification of ethanol in blood, urine and vitreous samples to make a reasonable estimation of uncertainty. The reporting of results will not give the wrong impression of uncertainty.

C. All components of uncertainty for quantification of ethanol in blood, urine and vitreous samples which are of importance have been taken into account. See BA.40 for more information.

1. Results of ethanol quantitation in biological samples will have an associated uncertainty reported when four replicate values are reported within the linear range.

2. The uncertainty will be reported on the average of the four analytical results; the final reported uncertainty will be rounded to no more than two significant figures.

3. The uncertainty for urine and vitreous samples will be reported on the unconverted average of the analytical results.

4. Uncertainty for blood, urine, and vitreous alcohol results will be reported in the report annex. See BA.11 for more information.
   a. Both unconverted and converted replicate values for urine and vitreous samples must fall within the linear range for the uncertainty to be reported.

5. The uncertainty will be reported in the same units as the result.

D. Refer to the BA.40 for specific information including the sources contributing to the uncertainty.

E. Definitions and Terms:

1. **Uncertainty** of a measured value is an interval around that value such that any repetition of the measurement will produce a new result that lies within this interval. This uncertainty interval is assigned by the experimenter following established principles of uncertainty estimation. Both type A and type B uncertainties exist.
1. Type A uncertainty is data from your laboratory (the lab generates based on control charts, etc)

2. Type B uncertainty is based on manufacturer's specifications, data from calibration reports, etc

2. Technical use of the word "uncertainty" indicates a level of confidence in the result or the test being performed or the measurement.

3. The laboratory has attempted to take into account in the uncertainty budget, the extent to which the following factors contribute to the total uncertainty of measurement of ethanol in blood, urine and vitreous samples.

   a. Human Factors
   b. Accommodation and Environmental Conditions
   c. Test and Calibration Methods and Validation
   d. Equipment
   e. Sampling
   f. Handling of Test and Calibration Items

4. **Accuracy** refers to the agreement between a measurement and the true or correct value. The concept 'measurement accuracy' is not a quantity and is not given a numerical quantity value.

5. **Traceability** refers to an unbroken chain of comparisons using acceptable and documented methods to national or international standards (SI) with each comparison having stated uncertainties. The measurement is what is traceable.

6. **Elements of traceability:**

   a. An unbroken chain of comparisons: an unbroken chain of comparisons going back to national (NIST) or international (SI) standards.
   b. Measurement uncertainty: the measurement uncertainty for each step of the traceability chain must be calculated and reported so that an overall uncertainty may be estimated.
   c. Documentation: each step of the chain must be performed according to documented procedures, and the results must be documented.
   d. Competence: laboratory performing steps in the chain must supply evidence of technical competence (eg. ISO 17025 accredited)
   e. Reference to SI units: where possible the chain of comparisons must end at the primary standards for the realization of the SI units (eg. BIPM)
   f. Recalibration at appropriate intervals: calibration must be repeated at appropriate intervals depending on the uncertainty required.
   g. Measurement Assurance: validates and verifies steps above

END OF DOCUMENT
I. Policy: The following is an explanation of the procedure used to estimate the uncertainty of Blood Alcohol analysis.

A. NIST 8-Step to estimating uncertainty

1. Specify the measurement process for the GC-FID

   \[ Y = mx + b \]

   Where:
   \( Y = \) ratio peak area of ethanol to peak area of n-propanol
   \( x = \) concentration of ethanol
   \( m = \) slope of the line
   \( b = \) intercept

2. Identify and characterize the uncertainty sources
   a. The Laboratory used "fishbone diagrams" and used brainstorming techniques to identify possible sources of error.
   b. See "Fishbone Diagram" at the bottom of the document.

3. Quantify uncertainty measurements
   a. The Laboratory uses "% W/V" (weight/volume) or grams per 100 milliliters of liquid.

4. Convert factors to standard uncertainties
   a. The Laboratory converted factors to standard uncertainties, one standard deviation equivalents, based on the distribution (normal or rectangular distribution) and the source of the data.

5. Calculate combined standard uncertainties
   a. The Laboratory uses the "root sum square" equation.

6. Expand the uncertainty by "k"
   a. The coverage factor is the multiplier used to establish the confidence level reported.
   b. The Laboratory uses a coverage factor of \( k=3 \) (approximately 99.73%)
7. **Evaluate the expanded uncertainty**
   a. The Laboratory evaluated the data and used Pareto charts to help visualize the significance of the contributing sources of uncertainty. The Laboratory plans to reevaluate the budget on an annual basis. If there is a change in the measurement process or the measurement instruments, the quarterly measurement assurance will be evaluated to determine if the changes are significant enough to require a full budget reevaluation.

8. **Report the uncertainty**
   a. The Laboratory reports the uncertainty in the same units as the blood alcohol result.
   b. The uncertainty for blood within the linear range of 0.02 - 0.50%: 6.26755536% of the average result.
   c. Blood alcohol results outside of the linear range will not be assigned uncertainty.
   d. The final reported uncertainty will be rounded to no more than two significant figures.
   e. The uncertainty for urine and vitreous will be reported on the unconverted analytical average.
   f. When the uncertainty is evaluated and determined not to be significantly different than a previous assessment, it may be left unchanged in the laboratory reports.
      i. A change that is not significantly different can be a minor incremental change in the uncertainty which is less than 0.2% lower than a previously determined uncertainty.

**B. GC-FID Budget**

1. The method involves the analysis of blood and urine specimens that have been diluted with an internal standard, sampled by an automated headspace sampler, and analyzed by gas chromatography. The quantitation of ethanol is accomplished through calculation of the relative responses (peak areas) of the ethanol and internal standard by the gas chromatographic separation of ethanol from other volatile substances. For the GC-FID budget, the Laboratory includes:
   a. **Matrix QC reproducibility**
   b. **Hamilton Diluter**
   c. **Instrument Readability**
   d. **Uncertainty of the Reference Material**

**C. Matrix QC Reproducibility:** The Matrix samples were prepared from certified reference materials using calibrated pipettes and flasks. The reproducibility of the samples incorporates many aspects of uncertainty including: instrument design, training, technique and environmental conditions.

**Reproducibility:** The Laboratory evaluates the difference of each fortified blood matrix solution from its target value. The Laboratory subtracts the value obtained during analysis from the target value. The differences are converted to a % so that
different matrix solutions can be evaluated. The Laboratory evaluates both instruments and the instrument with the highest standard deviation is included in the budget.

For the GC-FID budget, the uncertainty is expressed as %. The data is derived from the laboratory generated data therefore it is a Type A uncertainty and the Expanded Multiplier = 1, and the distribution is normal (Divisor = 1).

D. **Hamilton Diluter:** The digital diluter is used to dispense the blank, standards, QC's and samples by mixing the solution being dispensed with the internal standard. In the GC/FID budget, the dilutor is included twice as indicated below.

1. **Hamilton Calibration Uncertainty (Sample Syringe):** The Laboratory uses the manufacturer's imprecision (%CV) from the Heusser-Neweigh certificate. The manufacturer's imprecision is used as opposed to the measured imprecision such that the uncertainty would encompass all diluters that could be used to dispense samples. The User's Manual (Microlab 510B/511C, 530B/531C and 540B/541C) states that 30-100% stroke volume uses the same precision across the range (0.2%). The amounts dispensed during analysis are within this range (0.25 ml in 0.25 ml syringe =100% stroke volume).

2. **Hamilton Calibration Uncertainty (Internal Standard Syringe):** The Laboratory uses the manufacturer's imprecision (%CV) from the Heusser-Neweigh certificate. The manufacturer's imprecision is used as opposed to the measured imprecision such that the uncertainty would encompass all diluters that could be used to dispense samples. The User's Manual (Microlab 510B/511C, 530B/531C and 540B/541C) states that 30-100% stroke volume uses the same precision across the range (0.2%). The amounts dispensed during analysis are within this range (1.25 ml in 2.5 ml syringes =50% stroke volume).

   The data is derived from the calibration certificate (and applied to the volumes used during alcohol analysis based on the Manufacturer's specifications) therefore it is a Type B uncertainty and the Expanded Multiplier = 1, and the distribution is rectangular (Divisor = square root of 3).

E. **Instrument Readability for the GC-FID:** The effect of readability of the Perkin-Elmer GC-FID was evaluated by the Laboratory. For inclusion in the GC-FID budget, the maximum effect of readability is included.

1. **Instrument Readability:** The Laboratory includes the instrument readability based on the area under the curve being reported to a 0.01. This area readability comes into the measurement of ethanol as well as the internal standard, n-propanol. The area readability was added and subtracted from the area counts of ethanol and n-propanol from a standard chosen at random. By subtracting the highest combination from the lowest combination, the lab obtains the maximum effect of readability. This is converted to a % by dividing the maximum effect by value of the standard and multiplying by 100.

   The data is derived from a calculation based on laboratory data, therefore it is a Type B uncertainty and the Expanded Multiplier = 1, and the distribution is rectangular (Divisor = square root of 3).
F. **Uncertainty of the Certified Reference Material**: The uncertainty of the certified reference material.

1. **Certified Reference Material**: The uncertainty of the reference material is obtained from the manufacturer’s certificate. The largest uncertainty for all concentrations used was included in the budget.

The uncertainty is expressed as %. The data is derived from a certificate therefore it is a Type B uncertainty. The unexpanded uncertainty is used (as indicated on the certificate) and the distribution is normal (Divisor = 1).

G. **Blood Alcohol-GC-FID Explanation of Fishbone Diagram**

The purpose a fishbone diagram is to attempt to identify and characterize possible sources of uncertainty. The following explanation details where these sources are accounted for in the Laboratory's budget. The Laboratory attempted to account for each source on the fishbone diagram with at least one line item. There is not always a one-to-one relationship between the fishbone diagram and the line items.

1. **Design:**
   a. Instrument design (GC-FID Variability)
      i. Matrix QC Reproducibility
   b. Instrument design (Hamilton Diluter)
      i. Hamilton Diluter
c. Run drift
   i. Matrix QC Reproducibility
   ii. Validation

d. Reproducibility
   i. Matrix QC Reproducibility

2. **Installation:**
   a. Vendor/Internal Validation
      i. evaluated during Validation
   b. Software validation (data transfer/data manipulation)
      i. evaluated during Validation
   c. Location of equipment
      i. evaluated during Validation

3. **Staff: & Procedures**
   a. Experience/Training/Variability with different staff
      i. Matrix QC Reproducibility
      ii. Hamilton Diluter
      iii. procedures in SOP
   b. Technique of aliquoting (air bubbles, blanks, clots)
      i. Matrix QC Reproducibility
      ii. Hamilton Diluter
      iii. procedures in SOP
   c. Duplicate analysis of samples
      i. Title 17 administrative requirement as well as procedures in SOP
   d. Clarity of method/procedure
      i. Title 17 administrative requirement as well as procedures in SOP
   e. Truncation of result
      i. Title 17 administrative requirement as well as procedures in SOP

4. **Standards:**
   a. Standards
      i. Uncertainty of reference material
   b. Internal Standard
      i. not significant because the exact concentration of the internal standard
         n-propanol need not be determined as it is used in the calibration as
well as the calculation and the numerical value cancels out.

c. Reproducibility
   i. Matrix QC Reproducibility

d. Volatile nature of ethanol in standards
   i. addressed in SOP (expiration dates for standards and QCs based on stability studies)

5. **Facility:**

   a. Temperature Stability
      i. Matrix QC Reproducibility
      ii. *The correction factor for the thermometers was not taken into account in the budget as it is not a significant contributor to the overall uncertainty of the gravimetric checks.*

   b. Back-up Power
      i. not addressed in SOP

   c. Humidity
      i. Matrix QC Reproducibility

   d. Gas Supply
      i. Matrix QC Reproducibility

   e. Security
      i. addressed in Division Security policies

6. **Method of Use**

   a. Matrix Effect (blood/urine/vitreous vs. water standards)
      i. Matrix QC Reproducibility

   b. Preservative/Anticoagulant
      i. Matrix QC Reproducibility

   c. Urine/Vitreous-conversion to Blood Alcohol equivalents
      i. Uncertainty will be reported on the analytical results and will not encompass any uncertainty due to conversion.

   d. Scheduled Maintenance
      i. addressed in SOP

   e. Resolution of Instrument
      i. Instrument Readability

   f. Linearity-
      i. evaluated during Validation
END OF DOCUMENT
I. Policy: The following procedure is a guideline for training Criminalists to be authorized by the Laboratory as a Forensic Alcohol Analyst (FAA). An FAA performs analysis of biological samples for the presence/absence of ethanol and testifies to the analytical result in court.

A. Expectations

1. The training protocol for forensic alcohol analysis of biological fluids (blood, urine, vitreous and cavity fluid) will be used to train Criminalists in knowledge, skills, and abilities prior to being authorized to perform casework analysis. The laboratory's Forensic Alcohol Program is regulated by the California Department of Health Services (CDPH) and the "California Code of Regulations Title 17, Public Health Division 1, State Department of Health Services Chapter 2. Laboratories Articles 1-7" (Title 17). This training program is intended to supplement CDPH requirements and the requirements for testing in the ISO/IEC 17025 guidelines as the Laboratory is accredited by ANAB (ANSI-ASQ National Accreditation Board).

2. The training will minimally address the following topics:
   a. Understanding and comprehension of Title 17 and other required readings
   b. Value and purpose of forensic alcohol analysis
   c. Physiological action of alcohol
   d. Laboratory methods of forensic alcohol analysis
   e. Practical laboratory demonstration of the trainee's ability to successfully perform forensic alcohol analysis
   f. Interpretation of results of alcohol analysis
   g. Court testimony
   h. Court decisions regarding chemical tests of alcohol to determine alcohol influence
   i. Ethics in Forensic Science

B. Purpose

1. To understand the requirements in the Administrative Code of Regulations known as Title 17, the regulating agency (the California Department of Public Health) and the Laboratory procedures followed to become authorized as a Forensic Alcohol Analyst who can perform forensic alcohol analysis on biological evidence submitted to the Laboratory.

2. To develop knowledge, skills, and abilities in the area of alcohol analysis culminating in the ability to perform casework independently.

3. To understand and implement the policies and procedures in the Blood Alcohol Technical Unit Manual and Division Manual to perform casework in accordance with ISO/IEC 17025 and ANAB accreditation guidelines.

4. To gain expertise and knowledge on the use of instrumentation culminating in the ability to troubleshoot and perform routine maintenance on instrumentation.

5. To gain expertise in courtroom testimony through training and experience.

C. Education

1. An analyst will also meet any educational requirements set forth by the CDPH and Title 17 for qualification as a Forensic Alcohol Analyst prior to performing casework in the Forensic Alcohol Unit of the Laboratory.

2. An analyst must meet the minimum educational qualifications set forth in the ISO/IEC 17025 and supplemental guidelines from ANAB.

D. Training Records

1. Training Binder: Analysts will maintain a training binder to document progress in the Forensic Alcohol Unit of the Laboratory. At minimum the training binder should include the following:
   a. Authorization Checklist (ALC 36)
   b. Reading List
c. Statement of Qualifications

d. Competency and Proficiency documentation

e. Study Questions/Practical Applications

f. Court Critiques

2. The appropriate training records will be placed in the employee's training binder maintained by the employee and reviewed by the Manager/Supervisor upon completion of training. A summary of the training submitted to the Manager/Supervisor may include:

a. Topic of training

b. Number of practice samples examined and/or analyzed

c. Record of time committed to training

d. Verification that the training and proficiency testing to assess competency were successfully completed

e. Copies of certificates from courses taken

f. Court testimony

g. Mock court, if applicable

E. Effectiveness

1. Successful completion of the study questions, practical exercises, a competency test, and mock court will demonstrate the ability to perform forensic alcohol analysis and testify regarding forensic alcohol analysis and results.

2. The following are actions that may be used to evaluate effectiveness of initial training:

   a. Communication with Supervisor/Technical Lead throughout the training program

   b. Practical and written exercises and assessments as indicated in the documented training program

   c. Competency testing prior to assuming casework responsibilities

   d. Mock court exercises

3. The following are actions that may be used to evaluate the effectiveness of ongoing training:

   a. 100% technical and administrative review of casework

   b. Court critiques

   c. Oral or written feedback provided to Supervisor upon completion of training classes

   d. Yearly performance evaluation that includes setting goals for the analyst, review of SOQ, and training binder. This assessment reviews analyst goals for development and evaluates the effectiveness of training actions and if further training actions are needed.

4. Maintenance of skills and re-training:

   a. Maintenance of skills will be evaluated annually through proficiency training.

   b. Staff will be encouraged to attend on-going training by attending courses, meetings, and workshops.

   c. Presentation of evidence in court (eg. CCI class, courtroom monitoring, etc.).

   d. Training will be provided on any new equipment or methodology.

5. Remedial training:

   a. The need for remedial training may be implemented as a result of proficiency testing, courtroom testimony monitoring, and 100% technical review of casework. The remediation will be documented through a QA Action.

F. Timeline and Progress of Expectations

1. The training program for forensic alcohol analysis should take approximately 4 months culminating with a competency and mock court for alcohol analysis.

2. The progress or duration expectations for each section are as follows:

   a. 2 weeks to 1 month: orientations, job-shadowing, review of safety, unit and FSD policies and procedures

   b. 2-3 months: analysis of case-like samples, solution preparation and recordation, instrument theory and operation. The analyst should be assessed for readiness by the Supervisor prior to being given the competency test.

   c. At approximately 4 months and after the completion of a successful competency test a mock court will be given to assess understanding and courtroom presentation of evidence

G. Authorization for Blood and Urine Alcohol Analysis
1. The use of the authorization checklist (ALC 36) in conjunction with the documented training program is the manner in which management can ensure the competence of all who operate specific equipment, perform tests, evaluate results, and sign reports.

2. The ability to sign reports is the authorization for a Criminalist/Analyst to give their testimony about the analysis performed.

3. Refer to Alcohol Impairment Training (BA.45) for authorization of testimony regarding interpretation of results, the effects of alcohol on the human body, and alcohol impairment.

4. Training must be done in accordance with the documented training program.

5. A checkmark in the "Analyst" column indicates that the analyst has completed training in the area indicated. Initials in the "Trainer" column indicates who provided and supervised the training.

6. Personnel will be qualified on the basis of appropriate education (Supplemental 5.2.6.1.1), training as described in the training manual, and successful completion of competency test that demonstrate skills acquired.

7. The training program on pharmacology and pharmacokinetics of alcohol will be covered comprehensively in Alcohol Impairment Training (BA.45).

8. The trainee must successfully pass a competency before analyzing laboratory casework.

9. Refer to the Division Manual (FSD.21) for further information regarding training.

H. References

1. Trainer will review the references available and their locations with the trainee.

2. The location of the references may be within the Alcohol Unit, the Laboratory library, in PowerDMS, and/or electronically available to each trainee.

3. In addition to the specific references listed in each training Module, the trainee should also understand the following:
   a. Title 17-pertaining to Forensic Alcohol Analysis
   b. Blood Alcohol Technical Unit Manual
   c. Division Manual

II. Module 1: Historical Perspective on Blood Alcohol Analysis (Approximately 1 week)

A. Objectives/Topics of Study

1. Per Se Alcohol levels
   a. Current and historical perspectives of per se levels
   b. Per se level and impairment level

2. Theory
   a. Study of basic principles upon which forensic alcohol analysis is based

3. Single column vs. Dual column analysis

4. GC FID vs. GC/MS

5. California Department of Public Health Requirements

6. Basic physiology of the human body

B. References

2. Medicolegal Aspects of Alcohol Determination in Biological Specimens, James C. Garriott, editor, Lawyers and Judges Publishing Co., Tucson, AZ (2105), pages 259-263. (Garriott or Garriott's)

3. Blood Alcohol Analysis (ALCO.025)

4. Analysis of Samples by DCGC-FID (BA.30)

6. The Top 20 Myths of Breath, Blood, and Urine Tests-Part I

7. Chemical Tests for Intoxication: What Do the Numbers Really Mean? (ALCO.011)

8. Comparison of Ethanol Concentrations in Blood, Serum, and Blood Cells for Forensic Application (ALCO.002)
C. Study Questions/Practical Exercises
   1. What is the Laboratory's current method?
   2. Describe the difference between single column analysis and dual column analysis.
   3. Describe direct injection and headspace analysis.
   4. Define "Forensic Alcohol Analysis".
   5. Define Chromatography.
   6. What are the chemical properties of ethanol that lend itself to headspace chromatography?
   7. Describe the path alcohol takes when alcohol travels into & out of the human body after being ingested?
   8. In a DUl investigation, describe why time is important when obtaining a blood sample, analyzing the blood sample, and re-testing a blood sample?
   9. Why does the concentration of alcohol in a person's body differ in their blood, urine, breath, vitreous...etc.?
  10. Why does a person of 100 lbs and another person of 150 lbs. differ in blood alcohol concentration if they consume the same amount of alcohol?
  11. What are the units of measurement for Blood Alcohol? Breath Alcohol?
  12. Define the term "Proof" as it relates to alcohol content.

D. Assessment
   1. Trainer, or designee, will review and assess the answers provided by the trainee for the study questions and practical exercises. Written feedback will be provided to the trainee.

E. Documentation
   1. Answers to the Study Questions/Practical Exercises must be submitted to the Trainer, or designee, for review. Include this document in the analyst's training binder.
   2. Complete applicable sections of the Authorization Checklist (ALC.36).

III. Module 2: Evidence Handling/Specimen Handling and Safety (Approximately 2 weeks)
A. Objectives/Topics of Study
   1. Biological Evidence collection
      b. Procedure to obtain a proper blood or urine sample done accordance with Title 17.
   2. Proper evidence handling procedures including: opening evidence, selection of items to examine, marking of items, storage of evidence, disposition of evidence
   3. Safe handling of specimens, blood borne pathogens
   4. Proper documentation of specimens
   5. Chain of custody documentation
   6. Verification and marking of evidence
   7. Note taking
   8. Aliquoting requirements (sampling)
   9. Sample storage
   10. Evidence sealing
   11. Sending out OLA/referee samples
   12. Additional safety training classes are coordinated by the Safety Officer

B. References
   1. BA.08 - General Evidence Handling
   2. BA.10 - Technical Records
   3. BA.11 - Reports
   4. CLER.DAT.13 - Distribution of Reports
   5. FSD Safety Manual (SAF.01 - SAF.34)
C. Study Questions/Practical Exercises
   1. The trainee will observe the trainer, or an experienced analyst, performing the tasks identified above.
   2. Describe how the laboratory accepts evidence for alcohol analysis from Contra Costa County agencies.
   3. What happens to the lab report after it is draft completed by the analyst?
   4. How is the lab report distributed after the report has been technically and administratively reviewed?
   5. Describe how the evidence is handled after it has been analyzed and a report has been generated and reviewed.
   6. Describe how to locate the procedure for checking the calibration on the variable pipette.
   7. How is the Chain of Custody established and maintained when the evidence is received by the Laboratory?
   8. What should an analyst do if the information on the blood vials does not match what is written on the evidence envelope?
   9. Where is it documented if the blood evidence is consumed during analysis?

D. Assessment
   1. Trainer, or designee, will observe the trainee handle evidence and provide feedback.
   2. Trainer, or designee, will review and assess the answers provided by the trainee for the study questions and practical exercises. Written feedback will be provided to the trainee.

E. Documentation
   1. Answers to the study questions/practical exercises must be submitted to the Trainer, or designee, for review. Include this document in the analyst's training binder.
   2. Complete applicable sections of the Authorization Checklist (ALC.36).

IV. Module 3: Analysis/Equipment (Approximately 2 weeks)
   A. Objectives/Topics of Study
      1. Nature of Ethanol: Application, properties and important characteristics to consider:
         a. Ethanol, also called alcohol, ethyl alcohol, and drinking alcohol, is a compound and simple alcohol with the chemical formula C2H5OH. Its formula can be written also as CH3−CH2−OH or C2H5−OH (an ethyl group linked to a hydroxyl group), and is often abbreviated as EtOH. Ethanol is a volatile, flammable, colorless liquid with a slight characteristic odor. It is used as a drug and is the principal type of alcohol found in alcoholic drinks. Ethanol is naturally produced by the fermentation of sugars by yeasts or via petrochemical processes, and is most commonly considered as a popular recreational drug. It also has medical applications as an antiseptic and disinfectant. The compound is widely used as a chemical solvent, either for scientific chemical testing or in synthesis of other organic compounds, and is a vital substance utilized across many different kinds of manufacturing industries. Ethanol is also used as a clean energy burning fuel source. (Source-Wikipedia)
      2. When handling any sample containing ethanol to be analyzed consider the following:
         a. Caution taken when dispensing/testing sample to keep in a proper container to minimize exposure to air. The longer the sample is exposed to the air, the more ethanol loss over time.
         b. Flasks or beakers should not be utilized unless the sampling will occur immediately with few replicate analyses. Seal vials/containers with cap/lid when possible between dispensing.
         c. When a sample containing ethanol is to be stored, ensure the sample is kept in a tightly sealed container with minimal headspace to minimize evaporation and/or oxidation.
      3. Solutions
         a. NTRM Standards
         b. Internal standard solution of n-propyl alcohol
         c. Quality control solution
         d. Resolution check solution
         e. Standards and quality control materials prepared and run with each batch
         f. Criteria for reporting
         g. Use of the traceability database
   4. Instrumentation
      a. Learning the use and limitations of instruments
      b. Learning possible sources of error
c. Perkin Elmer Clarus 500 Gas Chromatograph with a flame ionization detector
d. Perkin Elmer Turbo Matrix 110 Headspace Sampler
e. Hamilton digital diluter with hand probe, Model 600, or equivalent
f. Pipettors, Eppendorf or equivalent, adjustable volume
g. Volumetric flasks
h. Thermometer
i. Balance
j. Sample preparation
k. Sample analysis and sampling
l. Checks of GC-FID and Headspace Unit
m. Prepare Blood alcohol kits for Coroner's cases
n. Sodium Fluoride Quality Assurance Check of Blood/Urine kits

B. References
1. Perkin Elmer User's Guide
2. Uncertainty of Measurement (BA.39 & BA.40)
3. Analysis of Samples by DCGC-FID (BA.30)
4. Care and Maintenance of Equipment and Environmental Conditions (BA.21)
5. Sodium Fluoride QA Checks for Kits (BA.35)
6. Uniform Standards for Withdrawal (BA.09)
7. GC-FID Routine Maintenance (BA.24)

C. Study Questions/Practical Exercises
1. Trainee will successfully make quality control standards at selected target concentration.
2. The trainee will analyze case-like materials as practice samples or mock casework. A lab report and notes will be generated to mimic actual casework. The reports will be reviewed by a current proficiency tested analyst to ensure current practices and procedures are being implemented and reviewed properly.
3. General
   a. For the following: NTRM Ethanol Standard, QC Solutions (water and blood), and the Run Calibration Curve, what criteria must be met for each for the results to be reported?
   b. The agreement between the replicate analyses of samples should not exceed what percentage? Why?
   c. What factors are taken into account for the uncertainty calculation? How is it reported?
   d. Why are there the four results given through the analysis of DCGC-FID? How is the uncertainty applied to the reported value?
   e. How is water-ethanol QC established? Why are there requirements?
   f. What volume is sampled for each of the following: Standards, QC's, Unknowns, and Internal Standard?
   g. How long are samples rocked before dispensing? Why?
   h. When choosing a blood vial for alcohol analysis, indicate the order of preference: red top serum separator tube, grey top tube, purple top tube. Why?
   i. What is the powder present in an unused blood vial? An unused urine container? Why is it there?
4. Dual Column GC-FID
   a. What are the gases used for in the blood alcohol DCGC-FID system? Identify the carrier and FID gases. Why are these gases used for analyzing ethanol in blood?
   b. Why is the lab using a dual column GC-FID system as opposed to the single column system?
   c. What are the temperature conditions in the dual column HS-GC? Why are those conditions important?
   d. Why is it important to turn on the FID approximately 30 minutes prior to starting a sequence run?
   e. How is the instrument being calibrated? Why is the lab not preparing the standards being used?
   f. How can an analyst determine if any maintenance is necessary on the instrumentation?
What type of maintenance can be done if the chromatography is not ideal?

Calculations

a. Calculate the alcohol concentration using the following information: Ethanol response: 206725.65, n-propanol response: 24394.81, slope: 59.625874, Y-intercept: -0.092496.

b. Calculate a vitreous alcohol result to be reported as a blood alcohol concentration.

D. Assessment

1. Trainer will observe the analysis of the samples and evaluate the completeness and accuracy of the exercises.
2. Trainer will evaluate the analytical results for accuracy.
3. Trainer, or designee, will review and assess the answers provided by the trainee for the study questions and practical exercises. Written feedback will be provided to the trainee.

E. Documentation

1. Answers to the study questions/practical exercises must be submitted to the Trainer, or designee, for review. Include this documentation in the analyst's training binder.
2. Complete applicable sections of the Authorization Checklist (ALC.36).

V. Module 4: LIMS (Report & Notes)/Computer Systems and Worksheets (Approximately 2 weeks)

A. Objectives/Topics of Study

1. Proper note taking in JusticeTrax LIMS
2. Proper report writing in JusticeTrax LIMS
3. Generating worklists
4. Uncertainty
5. Traceability
6. General laboratory paperwork and organization
7. Preparation of discoveries
8. The trainer will review the available references and procedures with the trainee, including:
   a. How to acquire a list of blood alcohol evidence awaiting analysis
   b. Discovery paperwork
   c. Referee paperwork
   d. Instrument maintenance logs
   e. Forms
   f. Certificates
   g. Alcohol files
   h. Traceability database

B. References

1. Laboratory Information Management System (FSD.10)
2. Using LIMS (BA.31)
3. Uncertainty of Measurement (BA.39 & BA.40)
4. Blood Alcohol Discoveries (BA.36)
5. Referee Analysis (BA.37)
6. GC-FID Routine Maintenance (BA.24)
7. Alcohol Database (BA.44)

C. Study Questions/Practical Exercises

1. The trainee will be instructed on general laboratory work flow and will then have the opportunity to use the Laboratory Information Management System (LIMS).
2. Trainee to perform practice sequence(s) using LIMS and alcohol analysis instrumentation.
3. Trainee will observe the processing of referee samples, discoveries, certificate of analysis review performed by a trainer or designee.

D. Assessment
1. Trainer, or designee, will review and assess the study questions and practical exercises. Feedback will be provided to the trainee.

E. Documentation
1. Trainer, or designee, to review practice sequence analysis packet.
2. Answers to the study questions/practical exercises must be submitted to the Trainer, or designee, for review. Include this document in the analyst's training binder.

VI. Module 5: Urine/Coroners (Concurrent: Approximately 2 weeks)

A. Objectives/Topics of Study
1. Correlation ratios of urine and vitreous to blood
2. 20 minute waiting period between void and urine sample collection
3. Accuracy of results for urine vs blood analysis
4. Peripheral and heart blood coroner samples
5. Postmortem redistribution
6. Potential issues with decomposition coroner's samples
7. Other volatile substances present in coroner's samples

B. References
1. Postmortem Production of Ethanol and Factors That Influence Interpretation: A Critical Review (ALCO.140)
2. Postmortem Redistribution (ALCO.139)
3. The Distribution of Ethanol in Postmortem Blood Specimens (ALCO.138)
4. The Unreliability of Using a Urine Ethanol Concentration to Predict a Blood Ethanol Concentration (ALCO.048)
5. Urine-Blood Alcohol Ratio: A Survey and Some Comments (ALCO.052)

C. Study Questions/Practical Exercises
1. Why is there a 20 minute waiting period when collecting a urine sample for alcohol analysis?
2. When a urine sample leaks and pools into the secondary container (bag), explain whether or not it is acceptable to test the leaked sample for alcohol content.
3. What are the advantages/disadvantages to each sample type for alcohol analysis: peripheral, heart, cavity, vitreous?
4. What special concerns are there when analyzing coroner's case samples?
5. How can an analyst know if the alcohol present in a coroner's sample is due to ante-mortem consumption?
6. What is the correction factor for UAC to BAC? What is the acceptable range from literature?

D. Assessment
1. Trainer, or designee, will review and assess the study questions and practical exercises. Written feedback will be provided to the trainee.

E. Documentation
1. Answers to the study questions/practical exercises will be submitted to the Trainer, or designee, for review. Include this document in the analyst's training binder.
2. Complete applicable sections of the Authorization Checklist (ALC.36).

VII. Module 6: Stability/Fermentation (Concurrent: Approximately 2 weeks)

A. Objectives/Topics of Study
2. Fermentation of alcohol in biological samples.
3. Measures and safeguards taken by the Laboratory to ensure proper collection and storage of biological samples and reference solutions for alcohol analysis.
   a. Preservative and anticoagulant testing for blood kits.
   b. Storage conditions for biological evidence.
   c. Storage conditions for reference solutions.

B. References

1. Garriott's pages 279-286
2. The Accuracy of Blood Alcohol Analysis Using Headspace Gas Chromatography When Performed on Clotted Samples (ALCO.001)
3. Blood Analysis by Headspace Gas Chromatography: Does a Deficient Sample Volume Distort Ethanol Concentration?
4. Efficacy of 1% Sodium Fluoride As a Preservative in Urine Samples Containing Glucose and Candid albicans (ALCO.041)
5. Alcohol Loss Arising from Microbial Contamination of Drivers' Blood Specimens (ALCO.037)
6. The Stability of Ethyl Alcohol in Forensic Blood Specimens (ALCO.034)
7. Methods of Assessing the Effect of Microbes in Blood and Urine on Ethanol Levels (ALCO.042)
8. The Bacterial Production of Ethyl Alcohol (ALCO.036)
10. The Stability of Alcohol in Stored Forensic Blood Samples (ALCO.039)
11. A Study of Blood Alcohol Stability in Forensic Antemortem Blood Samples
12. The Effect of Storage at Various temperatures on Blood Alcohol Concentration (ALCO.154)

C. Study Questions/Practical Exercises

1. What is fermentation? What are the conditions needed that would allow fermentation to occur in a blood sample collected for forensic alcohol analysis?
2. Does fermentation happen in every blood tube over time?
3. Is it possible for the alcohol content in a blood or urine sample to change over time? If so, why? If not, why not?
4. What are the typical changes in blood alcohol concentration over time for grey top tubes?
5. What causes these typical changes in concentration over time?
6. How long is the alcohol concentration stable in a grey top tube when stored at room temperature? Refrigerated? Why?
7. When dealing with a decomposition case, what should be tested? Why?

D. Assessment

1. Trainer, or designee, will review and assess the study questions. Feedback will be provided to the trainee.

E. Documentation

1. Answers to the study questions must be submitted to the Trainer, or designee, for review. Include this documentation in the analyst's training binder.
2. Complete applicable sections of the Authorization Checklist (ALC.36).

VIII. Module 7: Legal/Ethics (Concurrent: Approximately 2 weeks)

A. Objectives/Topics of Study

1. Court proceedings
   a. Preliminary Hearings
      i. Court 115's
   b. 402 hearings
2. Court decisions
   a. Frye vs United States
   b. Melendez-Diaz vs Massachusetts
   c. California vs Trombetta
d. Daubert vs Merrell Dow Pharmaceuticals

e. Birchfield vs North Dakota

f. Brady vs Maryland

3. California Vehicle Code

a. Violations or Public Offenses

i. 23136

ii. 23140

iii. 23152

1. 23152(a) & (b)

2. 23152(d) & (e)

3. 23152(f) & (g)

iv. 23153

4. Communication regarding Laboratory examination results

a. Required Laboratory documentation

b. Helpful information to gather before going to court

c. Limitations of testimony if not qualified in the area of alcohol impairment

5. Courtroom etiquette and protocol

6. ANAB and CAC code of ethics

7. Integrity of sample analysis and reporting true and accurate results

B. References

2. ANAB and CAC code of Ethics (PowerDMS)

3. Laboratory suggested Court topics for Alcohol Analysis provided to attorneys.

4. Garrott's pages 581-587

C. Study Questions/Practical Exercises

1. Observe a 115 with an experienced analyst (FAA).

2. Observe phone conversation with Deputy District Attorneys and experienced analyst (FAA) when a case is going to court.

3. Observe courtroom testimony for alcohol analysis with an experienced analyst (FAA).

4. Write a brief synopsis for each of the court decisions listed above.

5. Define each California Vehicle Code listed above.

6. Review ANAB and CAC Code of Ethics and discuss with trainer or designee

7. How does an analyst ensure that true and accurate results are being reported for a given sequence?

D. Assessment

1. Trainer, or designee, will review and assess the study questions/practical exercises. Written feedback will be provided to the trainee.

E. Documentation

1. Answers to the study questions/practical exercises must be submitted to the Trainer, or designee, for review. Include this document in the analyst's training binder.

2. Complete the applicable sections of the Authorization Checklist (ALC.36).

IX. Module 8: Traceability/UOM (Concurrent: Approximately 2 weeks)

A. Objectives/Topics of Study

1. Measurement Traceability

2. Uncertainty of Measurement

   a. Components of uncertainty associated with the quantification of ethanol in biological samples
b. Reporting of uncertainty associated with quantitative results

3. Measurement Assurance

4. Reference Materials
   a. NIST Traceable Reference Solutions

5. Reference Standards
   a. NIST Traceable Standard Solutions

B. References
   1. BA.39 Uncertainty of Measurement
   2. BA.40 Uncertainty Budget
   3. Measurement Traceability (FSD.28)
   4. Equipment Service and Calibration (FSD.33)
   5. Garriott's pages 531-563
   6. An Uncertainty Budget for the Measurement of Alcohol in Blood by Headspace Gas Chromatography (UM.04)
   7. Uncertainty in Estimating Blood Ethanol concentrations by Analysis of Vitreous Humor

C. Study Questions/Practical Exercises
   1. Define Uncertainty of Measurement.
   2. Observe the preparation when sending equipment being calibrated by an outside calibration vendor.
   3. Review the documentation included when receiving equipment from the outside calibration service.
   4. What is the current uncertainty of measurement associated with blood alcohol analysis in the forensic Alcohol Unit?
   5. What factors are considered in the Blood Alcohol Uncertainty Budget?
   6. Why is it important to use NIST Traceable solutions when performing alcohol analysis?

D. Assessment
   1. Trainer, or designee, will review and assess the answers provided by the trainee for the study questions and practical exercises. Written feedback will be provided to the trainee.

E. Documentation
   1. Answers to the study questions/practical exercises must be submitted to the Trainer, or designee, for review. Include this document in the analyst's training binder.
   2. Complete applicable sections of the Authorization Checklist (ALC.36).

X. Module 9: Testimony (Concurrent with other modules: Approximately 3 weeks)

A. Objectives/Topics of Study
   1. Presentation of evidence in court.
   2. Evidence handling
      a. Process by which evidence is received into the Laboratory
      b. Transfer of evidence in the Lab
      c. Chain of Custody
   3. Analysis of biological samples for the presence/absence of ethanol.
   4. Uncertainty associated with analytical results.
   5. Theory and operation of instrumentation used during analysis.
   6. Title 17 requirements
   7. Safeguards and precautions taken by the Laboratory to ensure evidence integrity and preservation
      a. Blood Alcohol Evidence Kits
      b. Evidence storage conditions
      c. Evidence retention
   8. Court critique
a. Requirement of obtaining an annual court critique
   i. Internal Court Critique Form (FSDF.02)
   ii. External Court Critique Form (FSDF.03)

b. Review of court critique with Supervisor/Manager

B. References
1. Court Testimony and Proficiency Testing (BA.19)
2. Court Testimony Monitoring (FSD.26)
3. Nonverbal Communication in the Courtroom (ALCO.116)
4. The Expert Witness and Communications Competency (ALCO.110)
5. Jury Preconceptions and Their Effect on Expert Scientific Testimony (ALCO.117)
6. Preparing Witnesses for Cross-Examination (ALCO.112)
7. The Technical Presentation (ALCO.113)
8. Garriott's pages 641-654
9. Court topics for blood alcohol analysis provided to the attorneys upon request

C. Study Questions/Practical Exercises
1. Explain the case workflow from the time you receive it until you seal it.
2. Diagram the HS-DGC-FID. Show how the sample moves from the vial through the instrument.
3. Review the Court topics for Blood Alcohol Analysis and discuss with trainer or designee.
4. Review court critique for critical content being reviewed when performing testimony

D. Assessment
1. Trainer, or designee, will review and assess the answers provided by the trainee for the study questions and practical exercises. Written feedback will be provided to the trainee.
2. Review of court critique with Supervisor, as necessary.

E. Documentation
1. Answers to the study questions/practical exercises must be submitted to the Trainer, or designee, for review. Include this document in the analyst's training binder.
2. Complete applicable sections of the Authorization Checklist (ALC.36).
3. Include copy of court critique in analyst's training binder once the mock court is assessed (from module 10).

XI. Module 10: Competency/Mock Court (Concurrent: Approximately 2 weeks)

A. Objectives/Topics of Study
1. The Criminalist may begin performing case work after successful completion of competency and upon authorization from the Manager/Supervisor. The training program may be abbreviated for analysts with previous experience in alcohol analysis.
   a. It is at the discretion of the Manager/Supervisor to abbreviate the training program based on previous experience. If the program is abbreviated, the previous experience will be documented.
2. At minimum, the competency will include:
   a. A Test of Knowledge will be completed encompassing alcohol analysis and Title 17 requirements with the following criteria:
      i. The test will be a closed book test
      ii. The criteria for evaluation will be a percentage of the total number of questions provided (i.e. 10 questions = 10 points per question). Trainee must receive ≥ 80% score on the Test of Knowledge to pass the written exam. Scores between 70-80% can be remediated with follow up clarification. Scores below 70% will be marked unsuccessful and will require documentation through a QA Action as well as further remedial training.
   b. An examination of 25 samples of known alcohol concentration. The results of these samples must not vary more than 5% from the re-analyzed result.
      i. Previously analyzed proficiency/competency samples may be used when any of the following steps are taken:
1. The identifying information of a previously used Proficiency sample will be coded by assigning it a different Agency Case #. For example, a previously used ACN like CTS 12-564 will be assigned an internal coded ACN with the unit and date - DRG-060412, ALC-060512, or TOX-060512 etc.

2. Ensure any identifying information is obscured and re-name the sample or samples may be transferred into new clean containers and labeled.

3. Previously analyzed samples and samples prepared in house (sample set) will be re-analyzed by a laboratory qualified analyst before assigning to trainee for testing. The results will be used for comparison.

4. The competency test will be performed within 10 days of the re-analysis of the sample set.

5. Samples may be prepared in house by a qualified analyst. Results of these samples will be within:
   1. +/- 5% (numerical value) of the expected target value for target concentrations between 0.080% ≤ X ≤ 0.500%.
   2. +/- 0.005 % (concentration) of the expected target value for target concentrations between 0.020% < X < 0.080%.

c. Ability to generate written report to properly convey results. The report should be generated in the same manner in which reports are generated for casework purposes.

d. An oral exam (mock court) to assess the individual's knowledge of the category of testing or task being performed.

B. References

1. Competency, Training, Authorizations & Ethics (FSD.21)
2. Jury Preconceptions and Their Effect on Expert Scientific Testimony (ALCO.117)
3. Training for Blood Alcohol Levels (ALCO.004)
4. Non-Verbal Communication in the Courtroom (ALCO.116)
5. Preparing Witnesses for Cross-Examination (ALCO.112)

C. Study Questions/Practical Exercises

1. Trainee will analyze practice samples of blood and urine prior to completing the Competency.
2. Trainee will produce at least one written report according to laboratory procedures for review by trainer or designee.
3. The trainee will be given an in-house Mock Court regarding analysis of biological samples for ethanol.

D. Assessment

1. An oral exam (mock court) to assess the analyst's knowledge of the category of testing or task being performed to show that the analyst can articulate their understanding in a clear and concise manner.

2. Results of all 25 samples analyzed must fall within allowable tolerance for the competency. If unsuccessful, remedial training will consist of more samples to be analyzed and a review of the trainees analysis procedures/technique.

3. Trainer, or designee, will review and assess the study questions and practical exercises. Written feedback will be provided to the trainee.

E. Documentation

1. Answers to the study questions/practical exercises must be submitted to the Trainer, or designee, for review. Include this document in the analyst's training binder.

2. Oral exam (mock court) written feedback provided to the trainee will be recorded in the analyst's training binder.

END OF DOCUMENT
I. The Alcohol Unit has quality procedures in place to ensure the reliability of test results.

   A. Assuring the Quality of Test Results

      1. The validity and quality of test results are ensured by doing the following:

         a. Regular use of reference materials water-ethanol quality control samples, with defined tolerance limits for quantitative purposes. See BA.13 and BA.15
         b. Periodic use of blood-ethanol quality control samples, with defined tolerance limits. See BA.15
         c. Participation in proficiency testing. See BA.19
         d. Functional check(s) of measuring and testing equipment. See BA.24 and BA.26
         e. Use of check or working standards with control charts. See BA.39
         f. Intermediate checks on measuring equipment. See BA.18 and BA.21
         g. Replicate tests or calibration using the same or different methods. See BA.30
         h. Retesting of retained items. See BA.37
         i. Review of reported results. See FSD.17, BA.10 and BA.18
         j. Intralaboratory comparisons. See BA.19
         k. Technical and administrative review. See BA.10 and BA.18

      2. Procedures and Test Methods

         a. Appropriate methods and procedures for all tests for testing alcohol. See BA.30
         b. Procedures for test data interpretation. See BA.30
         c. All methods, procedures, software or equipment must be validated or performance checked prior to use in casework. See BA.20.
         d. Instructions on the use and operation of equipment (see BA.24 and BA.30) and handling of evidence (see BA.08).
e. Sampling occurs prior to the lab handling the evidence when evidence is obtained from the subject. Procedures for further sampling see BA.08.

f. There is no comparison of unknown to a known as completed in other forensic disciplines. However, there are performance standards that must be met in order for the knowns' and unknowns' data to be considered suitable for the results to be valid and reportable. See BA.30

3. Environmental Conditions
   a. See BA.21 for Accommodations and Environmental Conditions for forensic alcohol analysis.
   b. For access to and use of areas affecting laboratory activities, see FSD.32 and BA.08
   c. Prevention of contamination, interference, or adverse influences on laboratory activities, see BA.08
   d. Effective separation between areas with incompatible laboratory activities are not an issue for alcohol analysis but proper care when cleaning glassware with any solvents is addressed in BA.27.
   e. Incorporating good housekeeping measures within the laboratory see BA.21.

4. Remedial Actions for Unsatisfactory Criteria
   a. If any issues arise from monitoring the quality control procedures listed above, the Supervisor or Manager will make a determination of the extent of the problem and take planned action. The following includes some, but not all, planned actions to correct any significant technical problems:
   b. If reference materials are found to be unacceptable due to deterioration or contamination they will not be used for casework.
   c. If a significant technical issue arises from the results of proficiency testing, the Supervisor or Manager will determine the extent of the issue, and if necessary open a corrective action to ensure incorrect results are not reported in casework.
   d. If a significant technical issue arises from 100% technical review of casework, the Supervisor or Manager will determine the extent of the issue and may open a corrective action that may entail: halting casework, retraining of an analyst, or rewriting of procedures. If the issue is not technically significant, the analyst will be given back the case for correction to ensure the correctness of test results.

5. The use of Quality Controls and Standards are specified in the procedure, and their use is recorded in the case record.
   a. For Quality Controls: See BA.15
   b. For Analysis of Samples: See BA.30
   c. For Technical Records: See BA.10

6. Quality Control samples will be recorded in a manner where trends are detectable and the data will be reviewed statistically. See Measurement Assurance below for the procedures.
B. **Measurement Assurance**

1. **General Information:**
   a. Measurement Assurance should be performed monthly.
   b. The evaluation should include the previous three months of data. If necessary, longer time periods may be evaluated to attempt to identify trends.
   c. Software may be used to perform a statistical evaluation using software, such as Access or Excel.
      i. The instructions included below are for using Excel.
   d. The measurement assurance should be documented and maintained within the unit.
   e. If there is a change in the measurement process or the measurement instruments, the quarterly measurement assurance will be evaluated to determine if the changes are significant enough to require a full budget reevaluation.

2. **Instructions for Using Excel for Measurement Assurance:**
   a. Open the Excel spreadsheet called Alcohol-Dual MA Template.xls, located in: L:\Lab\Muir\AlcDB.
   b. Once the spreadsheet is open, click on File, then Save As to save a copy of the spreadsheet. Save the copy in a location on your PC so that it can be edited without making any changes to the template.
   c. If not opened to the first tab, click on the first tab, named MAIN.
   d. Ensure the historical standard deviation is current.
      i. This can be found in UM.04, listed as the Combined Standard Uncertainty for the GC-FID Budget.
   e. Enter the Start Date for the beginning of the 3 month date range.
   f. Enter the End Date for the end of the 3 month date range.
   g. Click on the Update All button.
   h. Go to the first QC tab, i.e. DCPE1-Water.
   i. Evaluate the data and charts.
      i. See Evaluation and Criteria below.
   j. Adjust the charts so the data is legible.
   k. Once it is ready to print, click on the chart, click on File and then Print.
   l. Save as an electronic PDF copy in the L:\LAB\MUIR\Secure Alcohol\DISCOVERY RECORDS\Measurement Assurance folder.
   m. Repeat steps i. through l. for the second column chart.
   n. Click through the tabs and repeat steps i. through m. for all of the other QCs that have been run during the time period.
o. If a different time period is needed for a QC, the time period can be edited.
  i. Go to the QC tab that needs a different time period.
  ii. Edit the start and end date as needed and click **Import Data**.
  iii. Complete steps i. through m.
  iv. Repeat i. through iii. for any other QCs that need a different time period.

p. Once all of the charts have been electronically printed, they should be concatenated into one file and saved in the L:\LAB\MUIR\Secure Alcohol\DISCOVERY RECORDS\Measurement Assurance folder.
  i. The individual files should then be deleted.

3. **Evaluation:**
   a. Evaluate the percent difference of the results from the target value against the unexpanded uncertainty of the current blood alcohol budget. The limit lines correspond to k=1, k=2, and k=3, which are the standard deviations. The standard deviation can be found in UM.04, as the Combined Standard Uncertainty for the GC-FID Budget. This evaluation should be performed for:
     i. Water-ethanol QCs
     ii. Blood matrix QCs

4. **Criteria:**
   a. It is acceptable, and expected, that most data points will fall within the 1st limit line (k=1).
   b. It is acceptable for points to fall within the 2nd limit line (k=2). However, trends of data points beyond the 1st limit line may need to be explored as this may affect the blood alcohol uncertainty budget.
   c. If points fall beyond the 3rd limit line (k=3), then a written explanation should be included with the measurement assurance documentation. The written explanation should address potential sources of variation or larger percent differences and actions taken, if necessary.
     i. If there are any explanations are necessary, they should be entered in the Notes tab. The Notes tab should then be printed and concatenated with the charts.

C. **QA Action-Correction (QAC)**

1. An action taken to correct non-conforming work that has already occurred. The action taken to correct the nonconformity will be based on the severity of the non-conformance. QAC-3 is the least significant, QAC-2 is somewhat significant, and QAC-1 is the most significant non-conformity. Refer to FSD.15 for explanation of the types of QA Actions.
   a. Non-conformity: any aspect of testing or work product that does not conform to laboratory policies, procedures, or the agreed requirements of the customer.

   2. **QAC-3:** an action taken to correct a non-conformity when the significance of the non-conforming work is minimal and is unlikely to reoccur. The correction is readily
apparent and can be made quickly. The action will be taken immediately, often by the person observing the non-conformity. The non-conformity or action may or may not be documented. Examples may include:

a. A mis-shot on the instrument for case sample.
   i. Correction would be to fix any apparent issue and re-analyze.

b. Typographical error or data entry error that can be fixed before released.

c. Wrong Evidence type in LIMS that changes divisor (e.g. blood versus urine).

3. **QAC-2**: action taken to correct a non-conformity when the non-conforming work is of some significance and the investigation demonstrates that the non-conformity did not affect the validity and accuracy of the test result. QAC-2 corrections are actions made to prevent non-conformity in casework from being reported and will be documented. QAC-2 issues will be documented and maintained (electronically) in the Alcohol Tracking Database. The correction will be made. The documentation will be evaluated by a Supervisor/Manager periodically. The Supervisor will evaluate for issues or patterns of problems that may need to be elevated to a QAC-1. Examples of a QAC-2 may include:

   a. Quality controls not giving expected results (e.g. for the water and blood QC's).

   b. Standards not giving expected results (e.g. the STD's not passing criteria).

   c. Inappropriate storage of reagents or controls (e.g. left unrefrigerated) when it is subsequently demonstrated its use did not affect the validity and accuracy of the test result.

   d. Persistent problems identified during checking of reports (this would be documented by Tech Review).

   e. Unsuccessful runs.

4. **QAC-1**: an action taken to correct a problem or error resulting in erroneous results or conclusions issued for casework, proficiency testing or court testimony, when evidence is compromised or if the problem or error could recur. These issues must be documented immediately by a Supervisor/Manager, who must use the QA Action Procedure. The correction should be made as soon as possible. The action may involve stopping casework, re-training, competency testing, re-writing procedures, etc. Examples of non-conformities that would likely immediately rise to a Quality Action Correction-1:

   a. A technical problem or error results in erroneous results or conclusions being reported in casework.

   b. A technical problem or error results in an unsuccessful proficiency test.

   c. Erroneous court testimony is identified.

   d. Evidence is compromised.

   e. A non-conformity is identified in an audit.

**Contra Costa County**  
**Office of the Sheriff**  
**FORENSIC SERVICES DIVISION**  
**Blood Alcohol Technical Unit**  
**Manual**

**REVISION DATE:** 09/29/2016  
**NUMBER:** BA.43 - Case Record Imaging

**RELATED ORDERS:**

**APPROVED BY:**  
Joaquin Jimenez & Debbie McKillop

**ASCLD-LAB:**

**CHAPTER:**  
General Information  
**SUBJECT:**  
Case Record Imaging
I. The Alcohol Database is an Access database used to prepare logs and reports of supplies, consumables, and equipment that may effect analytical results. This may include NTRM standards, solutions, chemicals, equipment, and services that are critical to the quality of tests.

A. General Information

1. The database is split into a front end and a back end. The back end resides on a network server and contains the data. The front end resides on an individual’s computer and contains forms and reports for use. Multiple interfaces of the front end may exist to meet the needs of the various users.

   a. The front end is provided to users by placing a copy from the network server. **For use of the database, the user should copy the front end to their computer. The user should not use the copy on the server or create a shortcut to the copy on the server.**

   b. Changes can be made to forms or reports in the individual front ends without affecting other users. This allows the user to address issues with printer margins and labels.

2. The forms and reports are designed to provide the information required by the SOP, see BA.11. The appearance and location of forms and reports within the database as well as those produced by the database may change from the description here as long as it supplies the required information.

3. The Access database does not provide electronic audit trails of the information entered, therefore database/log records are printed from the database and maintained in the Alcohol Unit. Changes made after the record is created must be made on the printed copy and should also be updated in the database.

4. The database has been designed to include warnings to the analyst about expired and archived equipment and consumables. However, it is the responsibility of the analyst to ensure the equipment and consumables used are appropriate for analysis, and should not rely solely on the database.

5. For many categories, there is an option to have a reviewing analyst and a verification.

   a. Reviewing Analyst: It is **recommended** that at least one analyst, other than the analyst preparing a solution, initial and date the solution preparation log
and database log to document that the procedures were followed and the paperwork was completed correctly.

b. Verification: Procedures for the specific category should be followed in regards to verification, if one is needed. If a verification is done, it should be noted in the database and the sequence linked to the item. For solutions, this may or may not be the same analyst that made the solution.

B. Main Database

1. The primary consumables must be entered into the database in order to track sequences and preparation of laboratory generated solutions. These include:

   a. Chemicals
   b. Reference materials or ampules
   c. Matrix blanks
   d. Dry gas standards
   e. Solutions
   f. Reagents

2. For the various categories, there is an "Add" and a "View" button.

   a. The "Add" button opens a blank form for data entry.
   b. The "View" button opens a form listing all entries for that category in the database. The form includes some filter fields to narrow down the records. Basic Access filters and sorts can also be used.

3. Adding Consumables to the database

   a. In each of the categories, the lot number is the primary key. This means the database will not allow the user to enter multiple records with the same lot.

      i. If the “duplicate record” error is received, check the existing record to ensure the information previously entered is the same. Make sure the “archive” box is not checked.

   b. Chemicals

      i. Enter the chemical name, manufacturer, manufacturer lot number, and expiration date.
      ii. Many chemicals do not have expiration dates. If no expiration date is listed, leave blank.
      iii. The bottle must be initialed and dated when it is received into the laboratory.
      iv. If a certificate of analysis (COA) or other documentation is available, it can be linked to the record.

   c. Blank Matrix

      i. This includes blood and urine obtained from lab staff or from an outside vendor.
ii. Enter the type of matrix, lot number, source and expiration date, if applicable.
   1. If an outside vendor provides a lot number, that should be used.
   2. Matrix from lab staff can be named based on the date obtained and the initials of the individual providing the sample.
      1. For example, the lot number for a sample collected from John Doe on November 1, 2017 would be: 171101JD.
   3. Matrix from an outside vendor may have an expiration date, matrix from lab staff do not.

iii. Verification or screening for interfering substances may need to be performed.
   1. Matrix from lab staff or certified by vendor does not require verification.
   2. Blood obtained from a blood bank usually requires screening before use.
      1. Once screened, the documentation should be hyperlinked in the database and the lot should be marked as verified.

iv. There is a comment box that can be used to list anything important about the matrix. This may include if any substances were detected during the verification process or if preservative was added.

d. Standards - Ampules or Reference Materials

i. Most of the reference materials used in the Alcohol Unit are NTRM ampules of ethanol in a solvent and are received with a certificate of analysis (COA). Another reference material would be the dry gas canisters used for the breath instruments.

ii. For purchased standards, enter the manufacturer lot number, concentration, manufacturer, matrix, expiration date, number of items received.
   1. When entering the manufacturer lot number, the database will indicate when a duplicate entry is being created. A dialog box will open and clicking yes will delete the duplicate record being created.
   2. The concentration field is for the nominal concentration, located on the COA.
   3. For number of items received, enter the number of items received and be sure the "transaction" is "received." The date field will automatically populate. If the lot number was already entered in the database, add another "received" transaction and enter the number received in the new shipment.

iii. The “COA Link” field allows the user to link this record to a saved copy of the COA. Right click on the field, select the hyperlink menu, and then select “Edit Hyperlink.” A navigation window will open – navigate to the desired file and click OK. The link can also be created
by dragging the icon of the file to be linked from the Explorer window to the hyperlink field. Once saved, clicking on this field will open the file. COAs provided as print copies can be scanned to an electronic format for linking.

1. When hyperlinking, the COA file address should start with \\fs1 (preferred) or G:.

e. Review Ampules by date
   i. Enter the date new ampules were added to the database. A report will be generated showing all ampules added on that date. This can be checked by another analyst to review the entries for completeness.

4. Inventory
   a. Manufacturer Information
      i. In this form, new items can be entered. Enter the manufacturer, catalog number, concentration, and minimum number to have in stock, if needed.
   b. Current Inventory
      i. This prints a report of all ampules that have not been marked as archived and the number of ampules calculated to be present in the lab.
         1. It will list the total number present as well as the number present for each individual lot.
   c. Order Report
      i. This prints a report of ampules, with the catalog numbers, that need to be ordered.
         1. The report lists the number currently in stock based on the entries in the database, the minimum number to have in stock, and how many to order.
         ii. For the ordering report to work, it is important the ampules are tracked accurately. When an ampule is used in the making of standards or for analytical sequences it will be tracked in the database by entering the number of ampules used. Ampules that are not used directly (ie: discarded due to expiration) must be logged in the database. This is done by adding a "used" transaction and the number of ampules "used." It is recommended to do this from the record of the lot number of the ampule.
   d. Detailed Inventory
      i. The Detailed Inventory report tracks the transactions of physical ampules or gas standards. The report shows when an ampule was received and/or used.

5. Equipment
   a. Pipettes, volumetric flasks, diluters, balances, and GC/FID instruments are tracked within the database for calibrations and use in solutions and analytical sequences.
b. Equipment is added to the database using this form.
   i. Click "Add Equipment" and enter the equipment ID, serial number, type, manufacturer, model, and lab ID.
   ii. If a physical log was created, scan the log sheet and hyperlink it to the entry.

c. The Equipment form will display the records for all equipment in the database.
   i. Checks of the equipment are entered for in-house and professional checks.
      1. Click "edit record" and scroll to the empty boxes. Include whether it was an in-house or professional check, the date, the next calibration due date, and analyst. If it was an in-house check, enter the equipment used in the boxes below the check information on the form.
   ii. Supporting documentation should be hyperlinked.
   iii. The "Logs" section, on the right, shows the hyperlinked physical maintenance logs.

d. It is important to add the next calibration date so that it will show up on the "Cal Due" list. This can be accessed from the main menu.

e. DCPE1 and DCPE2 have buttons on the main menu that allow an analyst to view and add a maintenance log entry.
   i. To add a log entry, select the component, the date, analyst initials, the problem, and the action taken.

6. Solutions
   a. Laboratory generated solutions include internal standards, resolution solutions, water/ethanol QCs, and matrix QCs.
   b. Adding a solution
      i. The assigned lot number must be unique, and is typically based on the type of solution, date of preparation, and concentration (if applicable). For example: YYMMDDXXXX, where XXXX is the concentration. The following conventions may be used:
         1. IS: Internal Standard - ISYYMMDD (Refer to BA.16)
         2. RS: Resolution Solution - RSYYMMDD (Refer to BA.17)
         3. QC: Water/Ethanol QC - QCYYMMDD-XXXX (Refer to BA.15)
         4. CCCL: Lab prepared Blood Matrix QC - CCCLYYMMDD-XXX (Refer to BA.15)
         5. For purchased blood matrix QCs, the solution ID is the lot number from the vendor and concentration. For example, a 0.084% blood matrix QC from Utak with a lot number of A5005 would be UTAKA5005-084.
1. For date prepared, enter the date received.

ii. Enter the Solution ID, prep date, analyst, solution type, target value, expiration date, and volume prepared, including units. Include all chemicals, standards, equipment, and matrix, if applicable, used to create solution.

1. If any of these have not been entered in the database, a "null" error will appear. That information will need to be entered before continuing. Close the subform and the record will be deleted. Once the information has been entered, click "Add Solution" and start over.

2. When an ampule is used, it is important the ampules are tracked accurately. Correctly enter how many ampules were used to make the solution. The default number is 1, but if using a previously opened ampule, set the number to 0.

3. If the ampule has been linked to a saved COA, click on the link to view it. Check the COA to ensure the certified concentration is the same as the nominal concentration. If different, use the certified concentration for preparation of solutions.

4. The expiration date should be entered based on procedures or the earliest expiration date of the components. If there is no expiration date, leave blank.

5. The "Print Record" will print the solution log. Print the log and keep on file in the Alcohol Unit. Once the solution has been verified and reviewed, both the physical log and database log need to be updated.

6. The "Print Label" will print a label that can be placed on the bottle. This information must be on the bottle, but it is not necessary to print this label. If desired, print this label and tape it to the bottle.

7. The "Biohazard-med" will print identification labels. Enter the amount of blank spaces/labels to skip, enter the number of copies needed, and then physically print the label(s). The Avery 2/3 x 1-3/4" (Avery 5155) labels are used for this button. This can be used on a small, refillable bottle.

8. The "Biohazard-small" will also print identification labels, but uses the Avery 1/2 x 1-3/4" (Avery 5167) labels. Enter the amount of blank spaces/labels to skip, enter the number of copies needed, and then physically print the label(s). This can be used on a small, refillable bottle.

iii. Once verified, the supporting documentation should be hyperlinked, as well as the verified box checked, the date verified, the sequence ID, if applicable, and the analyst.

iv. When making a Title 17 QC solution, the target value cannot be entered until it has been established. All other information should be entered into the database before preparation to ensure all chemicals, standards, etc., are not expired. The intended target concentration may be entered
until the established concentration can be entered. Once the QC concentration has been established per procedure, it is important that the established value be entered in the database as the "target value."

7. Verify Solutions
   a. Laboratory generated solutions must be verified. This will generate a list of all items entered but not verified.
      i. Most solutions are verified by successful use in a sequence. Independent verification prior to use in casework is not required.
      ii. Verification must be recorded in the database and on the physically printed form.
         1. The purpose of verifying in the database is to keep track of solutions that need to be verified.
         2. If a solution is not successfully verified and will not be used or will be discarded, the verified box should be checked in the database so that it will not appear in forms/reports. A comment can be added in the sequence field that it will not be used. Include the date and your initials.
      iii. Individual solution forms also contain a section to add verification.

8. Archive
   a. Archiving consumables and solutions is important to prevent inadvertent use of old lots and will minimize the size of drop-down lists.
   b. The form contains tabs for each of the different consumables/solutions.
      i. Within each tab is a list of all unarchived consumables/solutions. Find the item to be archived and check the archive check box.
   c. Archiving should be done once a lot has been consumed, discarded, or expired.
   d. If additional supplies of a consumable are received and it has already been marked as archived, the archive box should be unchecked before adding another transaction.

9. Sequence
   a. The traceability form allows data entry of all the lot/serial numbers used in an analytical sequence.
   b. To start a new sequence, click "Add Sequence."
      i. The sequence ID must be unique. It is typically based on the date analysis begins and the instrument. Sequences are designated A, B, C, etc., as needed to ensure each sequence on the same instrument on the same day has a unique identifier. For example, 160701A DCPE1 would be the first sequence run on July 1, 2016 on instrument DCPE1.
      ii. Lot numbers for solutions and standards must already be in the database.
1. Any ampule used in a sequence would be a standard. The "Standard ID" is the lot number assigned by the manufacturer. The correct number of ampules used must be entered. It is **important the ampules are tracked accurately.** The default number is 1, but if using a previously opened ampule, set the number to 0.

   1. If the Title 17 QC was an ampule, it would be put in the standards.

2. The IS, RS, and Matrix QC, if used, would be the solutions used.

   1. If the Title 17 QC used was made in house, it would be put in the solutions.

3. By entering the lot number, all other information should be populated automatically. Barcodes can be scanned where available.

   c. Adding Results

   i. Results are added after the instrument has completed the sequence.

   ii. Results can be entered manually or imported.

      1. To enter manually, click "Add Results" and simply type in the results for each standard and QC.

      2. To import the results, the text file created from running the sample report on the instrument is used.

         1. In the sequence entry, click "Import Std Results," Navigate to an odd numbered case text file (generated when the sample report is run) and select it. Since all odd numbered files have the same formatting and information needed, it does not matter which one is chosen. The results for the standards will be imported automatically, assuming the curve levels are as follows:

            1. Level 1: 0.0200%
            2. Level 2: 0.0500%
            3. Level 3: 0.1500%
            4. Level 4: 0.3000%
            5. Level 5: 0.5000%

         2. A form will then show the QC results. The correct QC lot must be assigned to the correct results. Then click "Update," otherwise the QC results will not be imported.

            1. If the same lot of QC was used more than once in the sequence, only one set of results will import. The rest will need to be put in manually.
3. The "Sequence Traceability Worksheet" will open. Double check that all information has been imported and is correct. If all is correct, digitally print the worksheet by clicking "PDF or XPS." Save the file so that it can be included in the summary run packet.

1. If something failed to import, close the worksheet and go back to "Add Results" and manually enter the data. Then print the "Worksheet w/ Results" and verify all information is now there. If all is correct, digitally print the worksheet to be included in the summary run packet.

iii. Once the sequence packet is completed, it should be hyperlinked to the sequence. The Tech/Admin reviewer can sign the packet and it will stay linked so long as the name of the file and file path does not change.

iv. The comment field may be used as necessary.

   1. **Note:** whatever is written in this field will print on the traceability sheet.

v. The "Sequence Traceability Worksheet" will also need to be added to the case notes.

   1. In order to do this, the LIMS worklist must be imported.

   1. Within the sequence screen, click on "Import Worklist."
   Then navigate to the text file generated by LIMS when sending the worklist to the DCPE instrument.

   2. Once all information on the traceability worksheet is verified, click "LIMS Worksheets." A dialog box will open with a reminder to ensure all other worksheets have been deleted from the C:\Temp folder. If all other worksheets are deleted, click ok. All of the worksheets will automatically print to the C:\Temp folder. Use JusticeTrax Batch Imager to load from a batch file and select "worksheetBatch" in the C:\Temp folder. Uncheck the box "Send BA Val to LIMS", login with your LIMS username and password. Review the Traceability Worksheet to be placed into each lab number request and send to LIMS by clicking "Submit to LIMS."

10. Quality Form

   a. **All failed runs must have a log entry.** An entry related to a sequence should be added by clicking the "Quality Log" button on the sequence form. An entry not related to a sequence can be added through the "Quality Form" button on the main menu. The log can also be reviewed by using the "Quality Form" button.

   i. The log allows for additional information to be added but will not appear on the traceability worksheets. This may include information such as running the sequence on a different instrument or changes in instrument parameters. If the run was completely unrecoverable, check the “Failed” box. This may be used to track any other “non-
conformities." See BA.42 – Test Quality and Corrections for the types of issues that require a log entry.

11. Backup
   a. The front and back end of the database should be backed up periodically. It is recommended to be backed up weekly to an external hard drive. The external hard drive should be checked at least quarterly to ensure the backup files are stored properly.

END OF DOCUMENT
I. Policy: The training protocol for the Forensic Alcohol Unit will be used to train Criminalists in knowledge, skills, and abilities prior to being authorized to testify regarding the effects of alcohol on the human body and alcohol impairment. The Laboratory's Forensic Alcohol Program is regulated by the California Department of Public Health Services (CDPH) and the "California Code of Regulations Title 17. Public Health Division 1. State Department of Health Services Chapter 2. Laboratories Articles 1-7" (Title 17). This training program is intended to supplement the requirements of CDPH and Title 17. This training is also part of the authorization by the laboratory to be a Forensic Alcohol Analyst (FAA).

A. Expectations

1. Understanding and comprehension of Title 17 and the Laboratory's Forensic Alcohol Program.

2. Interpretation of results of alcohol analysis, including correlation of alcohol analysis with subjective observations of the demeanor and behavior of persons who have ingested known amounts of alcohol.

3. The trainee will coordinate and conduct an alcohol impairment study to observe the effects of alcohol and alcohol impairment in a controlled environment.

4. The trainee will participate in Ride-Alongs to observe driving patterns, objective signs and symptoms, and field sobriety testing of subjects suspected of driving under the influence of alcohol in the field.

5. To gain expertise in courtroom testimony and alcohol impairment through training and experience.

6. The training will minimally address the following:
   a. Value and purpose of forensic alcohol analysis.
   b. Physiological action of alcohol.
   c. Pharmacology and toxicology of alcohol.
   d. Laboratory methods of forensic alcohol analysis.
   e. Instruments and procedures for breath alcohol testing.
   f. Interpretation of results of alcohol analysis, including correlation of alcohol analyses with subjective observations of the demeanor and behavior of
persons who have ingested known amounts of alcohol.

g. Field Sobriety Testing.
h. Drink Calculations.
i. Retrograde extrapolation.
j. Court testimony.
k. Requirements of Title 17.
l. General Forensics
   a. Analysts should develop a general knowledge of other forensic disciplines that may often be related to evidence processing such as:
      i. Latent prints
      ii. Biology/DNA
      iii. Toxicology
         1. Toxicology involves drugs, uses similar instrumentation and is often related to drug cases. Analyst should have an understanding of the differences in analysis, how instruments are used and reporting of results for toxicology evidence compared to drug evidence.
      iv. Firearms
   b. This knowledge may be obtained from a variety of sources
      i. Formal education in Criminalistics or Forensic Science
      ii. Supplemental reading of general forensic texts
      iii. Observation of analysts in other disciplines at the laboratory
      iv. Certification that has a general knowledge requirement

B. Purpose

1. To meet the requirements of the CDPH and Title 17 to be qualified as a Forensic Alcohol Analyst who can provide expert witness testimony regarding all aspects of the Laboratory's Forensic Alcohol Program, the effects of alcohol on the human body, and alcohol impairment.

2. To understand and implement the policies and procedures in the Forensic Alcohol Unit for the analysis of biological samples for ethanol, the interpretation of the results, the effects of alcohol on the human body, and alcohol impairment.

C. Education

1. Analysts working in the Forensic Alcohol Unit shall possess a baccalaureate or an advanced degree in a natural science, criminalistics, or a closely related field (Supplemental 5.2.6.1.2). Analysts will additionally meet any educational requirements set forth by the CDPH and Title 17 for qualifications as a Forensic Alcohol Analyst (FAA).
1. The appropriate training records will be placed in the analyst's training binder. The training binder will be maintained by the analyst and reviewed by the Manager/Supervisor. Minimally the training binder will include the following:
   a. Authorization Checklist (ALC.35 and ALC.36)
   b. Reading list
   c. Study questions/practical exercises
   d. Summary of Ride-Alongs
   e. Competency and proficiency records
   f. Updated analyst Statement of Qualifications (SOQ) after attendance at any workshop, technical meeting, or training class
   g. Court critiques

2. Report summary of Alcohol Impairment Study
   i. Calculations done for drinking subjects
   ii. Results from breath, blood, and urine analysis
   iii. Subject performance on divided attention tasks and sFST's
   iv. Conclusions reached based on findings of in-house impairment study

3. Effectiveness
   1. The following are training actions and can be used to evaluate the effectiveness of initial training:
      a. Communication with trainer and/or Supervisor throughout the training program.
      b. Practical and written exercises as indicated in the documented training program.
      c. Impairment Study summary report.
      d. Mock court exercises.
   2. A Forensic Alcohol Analyst will demonstrate the ability to provide expert witness testimony regarding the effects of alcohol on the human body and alcohol impairment upon successful completion of the following:
      a. Study questions
      b. Alcohol impairment study
      c. Mock court for alcohol impairment
      d. Written forensic alcohol analyst questions
   3. The following are training actions and can be used to evaluate the effectiveness of on-going training:
      a. Oral or written feedback provided to trainer upon completion of training classes.
b. Court critiques
   i. Internal Court Critique (FSDF.02)
      1. To be completed by experienced Laboratory personnel
   ii. External Court Critique (FSDF.03)
      1. To be completed by the Prosecution, Defense Counsel, or presiding Judge

4. Remedial Training
   a. Remedial training may be implemented as a result of:
      i. Proficiency testing
      ii. Courtroom testimony monitoring
      iii. 100% of technical review of casework
   b. The remediation will be documented through a QA Action.

5. Duration of Training:
   a. In general, the trainee is expected to complete the Alcohol Impairment Training within approximately one year after entering the alcohol unit.
   b. The training duration can be altered depending upon the trainees prior knowledge, experience, and initiative to complete the modules.
      i. If training is adjusted, written documentation (email, letter, or memo) will be provided by the Supervisor or Manager.
   c. The Alcohol Impairment Training is intended to happen concurrently with blood alcohol and breath alcohol analysis training.

6. A yearly performance evaluation will be an assessment to review an analyst's development and evaluate the effectiveness of training actions. The yearly review includes:
   a. Setting goals for the analyst
   b. Review of SOQ
   c. Review of training binder

F. References
   1. Trainer will review the references available and their locations with the trainee.
   2. The journal articles referenced are mandatory readings.
   3. The textbook references are mandatory so far as the sections of the book that are pertinent to the topic of study within each module where they are referenced.
   4. In addition to the specific references listed in each training Module, the trainee should also understand the following:
      a. Title 17 - Forensic Alcohol
      b. Blood Alcohol Technical Unit Manual
c. Breath Alcohol Technical Unit Manual

d. Division Manual

e. Alcohol Literature Binder Index (ALCO.211)

i. Articles and references are available on PowerDMS and the Laboratory shared drive.

II. Module 1: Pharmacology and Physiology of Alcohol - (Duration ~2 months)

A. Objectives/Topics of Study

1. Chemistry and Biochemistry of Alcohol
2. Pharmacokinetics of Ethanol
3. Pharmacodynamics of Ethanol
4. CNS Depressants
5. Absorption, Distribution, Elimination
6. Arterial/Venous Differences
7. Coroner's samples

B. References

1. Absorption, Distribution and Elimination of Alcohol: Highway Safety Aspects (ALCO.021)
2. Widmark's Hypothesis; ABC of Widmark's Beta and Rho (ALCO.031)
3. Variation in Blood Alcohol concentration Following the Last Drink (ALCO.008)
4. Blood Alcohol: The Concentration-Time Curve and Retrospective Estimation of Level (ALCO.027)
6. Elimination of Ethanol in Humans (ALCO.009)
7. Garriott Chapter 2 (3.5), (3.6), (3.7) (4.3), (4.4) Variation in Blood Alcohol Concentration Following the Last Drink
8. Evaluation of Blood-Ethanol Profiles After Consumption of Alcohol Together with a Large Meal
9. Influence of Age, Gender, and Blood-Alcohol Concentration on the Disappearance Rate of Alcohol from Blood in Drinking Drivers (ALCO.014)
10. The Calculation of Blood Ethanol Concentrations in Males and Females (ALCO.015)
11. Peak Blood-Ethanol Concentration and the Time of Its Occurrence After Rapid Drinking on An Empty Stomach
12. The Metabolism and Pharmacokinetics of Alcohol in Man (ALCO.006)
13. Blood Alcohol Concentration Determined from Urine Samples as a Practical Equivalent or Alternative to Blood and Breath Alcohol Tests (ALCO.049)
C. Study Questions/Practical Exercises

1. Draw a blood alcohol curve.
2. What is the acceptable range for elimination rates? What are some of the factors that may affect the elimination rate?
3. What is the acceptable range for absorption rate? What are some of the factors that may affect absorption?
4. What role does the gender or weight of an individual play in absorption, if any?
5. Explain how alcohol is distributed throughout the body after it is ingested by the mouth.
6. How do A/V alcohol concentrations change over the course of the breath curve?
7. What is the scientific basis for correlation ratios?
8. How does the correlation ratio change as the alcohol curve changes?

D. Assessment

1. Trainer, or designee, will review and assess the answers provided by the trainee for the study questions and practical exercises. Written feedback will be provided to the trainee.

E. Documentation

1. Answers to the study questions/practical exercises must be submitted to the trainer, or designee.
2. The trainer or designee will review and provide written feedback (signed and dated) and the trainee will include this documentation in their training binder.

III. Module 2: Impairment/Impairment Study - (Duration ~2 months)

A. Objectives/Topics of Study

1. Behavioral and Performance Effects of Alcohol on Driving
2. The Role of BAC and Complexity of Driving Task Impairment
3. Tolerance

B. References
1. NHTSA website: [https://www.nhtsa.gov/risky-driving/drunk-driving](https://www.nhtsa.gov/risky-driving/drunk-driving) (many resources within NHTSA website)

2. Alcohol Tolerance and Its Significance in Driving (ALCO.102)

3. Tolerance at High Blood Alcohol Concentrations: A Study of 110 Cases and Review of the Literature (ALCO.103)

4. Acute Intoxication and Tolerance Pharmacology of Alcohol (ALCO.020)

5. Laboratory Studies of the Effects of Alcohol on Some Variables Related to Driving (ALCO.059)

6. Alcohol Effects on Driver Performance Under Conditions of Divided Attention (ALCO.062)

7. The Role of Drinking Drivers in Traffic Accidents (ALCO.068)

8. The Influence of Alcohol on Automobile Driving Ability (ALCO.070)

9. Skill Performance at Low Blood Alcohol Levels (ALCO.072)

10. Alcohol and the Driver Council on Scientific Affairs (ALCO.074)

11. The Effect of Alcohol on Human information Processing Rate (ACLO.075)

C. Study Questions/Practical Exercises

1. Practical Exercise: Coordinate and conduct an alcohol impairment study.
   a. Participant coordination:
      i. Locate male and female volunteer drinking subjects
      ii. Officers to administer sFST's
      iii. Blood technician
      iv. Laboratory Staff for their assistance
   b. Calculate amount of alcohol needed for the drinking subject to reach a blood alcohol level of 0.08% - 0.10%.
   c. Design tasks/tests that require divided attention and associated clues to assess the performance on the divided attention tasks.
   d. Calculate elimination rate for the drinking subjects.
   e. Correlate subjects' blood alcohol level and impairment.
   f. Correlate subjects' blood, breath, and urine results.

2. What is tolerance as it relates to alcohol? Despite a person's tolerance, is there a level at which all people are significantly impaired for the purpose of safely operating a motor vehicle?

3. Defend your opinion about impairment with literature sources and articulate why you believe individuals are impaired for the purpose of driving at the level chosen in 2.

4. What is the difference between fine motor skills and gross motor skills? Which are affected first by alcohol?
5. Can a person be impaired at 0.05% BAC? Why? What signs, symptoms or clues of impairment would you expect to observe at low BAC levels?

D. Assessment

1. Trainer, or designee, will review and assess the answers provided by the trainee for the study questions and practical exercises. Written feedback will be provided to the trainee.

E. Documentation

1. Answers to the study questions/practical exercises must be submitted to the trainer, or designee, for review.

2. The trainer or designee will review and provide written feedback (signed and dated) and the trainee will include this documentation in their training binder.

3. Alcohol impairment study summary report: Compile results from psychomotor tests and chemical tests. Include a summary of results, interpretations, and conclusions made during the study. Submit summary report to the trainer for review. Trainer will review, sign and date, and provide written feedback.

IV. Module 3: Calculations/Statistics/Uncertainty - (Duration ~1 month)

A. Objectives/Topics of Study

1. Consideration of assumptions to be made when asked to do a retrograde extrapolation

2. Approaches to Widmark Calculations

3. Practice and pitfalls of Retrograde Extrapolation

4. Drink Calculations

5. Blood correlation calculations
   a. Blood to breath alcohol concentrations
   b. Blood to urine alcohol concentrations

6. Basic principles of Mathematics and Statistics in Alcohol Toxicology

B. References

1. Uncertainty of Measurement (BA.39)

2. Uncertainty Budget for Blood Alcohol (BA.40)

3. Dealing With Uncertainty in Chemical Measurements - March 2003 (ALCO.207)

4. Alcohol Content of Beer and Malt Beverages: Forensic Considerations (ALCO.125)

5. Widmark's Hypothesis; ABC of Widmark's Beta and Rho (ALCO.031)

7. The Calculation of Blood Ethanol Concentrations in Males and Females (ALCO.015)

8. Widmark's Equation (ALCO.030)

9. Pharmacology and Toxicology of Ethyl Alcohol (ALCO.029)

C. Study Questions/Practical Exercises

1. What assumptions should be made when considering a back calculation?

2. Is there an error rate associated with the calculation of the number of drinks in a person's system? Explain.

3. If the test subject's correlation factor is 1600, with a breath alcohol result of 0.07%, calculate what this person's breath result would be. What is the scientifically accepted blood:breath correlation?

4. Given: 150 lb. male who consumes (5) glasses of wine from 6pm - 9pm. What is his BAC at 11 pm?

5. Given: 150 lb. male with a PAS result of 0.10% BrAC at 11pm. Same person had their blood drawn at 1:30 am and the blood result was 0.09%. Can you back extrapolate to 11 pm with the given blood result? How and why? Explain the discrepancy between the PAS and back-extrapolated result.

6. Given: 150lb male with a BAC of 0.09% from a blood draw at 1:00 am. Can you back extrapolate to 11 pm with the given blood result?

7. Can you back extrapolate to 11 pm with the given blood result if the individual says that their last drink was consumed at 10:55 pm?

8. Given: 170 lb. female who consumes (4) 40 oz. beers from 6pm-9pm. What is her BAC at 11 pm?

9. Given: 170 lb. female who consumes (4) 8% beers from 6pm-9pm. What is her BAC at 11 pm?

10. Given: Breath alcohol results: IR 0.09%, FC 0.10%, IR 0.09%, FC 0.11%, how many drinks were in this 135 lb female subject at the time of the test?

11. If it was determined that ten 12 oz. beers (4% ethanol) were consumed for an individual to be at 0.20%, how many drinks would have been consumed if the beers were 8% microbrew? How many drinks would be consumed if it was a 15% malt beverage? How many drinks if it were a Long Island Iced Tea?

12. Given: 240 lb male with blood alcohol results of 0.25%. How many drinks are in his system at time of blood draw? How many 40 oz. malt liquor (8.2%) drinks are in his system? How many 1 oz. shots of Tequila?

13. Given 220 lb female at 0.19%; how many beers did she have in her system? How many 22 oz. microbrew beer (9%) drinks did she have?

14. Given 95 lb female at 0.21%; how many ounces of NyQuil (10%) did she have? Tequila shots? Sam Adams Utopias (28%)?

15. If a 200 lb male crashed car into a light pole across the street from home and drank after driving, how many drinks would he have had to consume after driving to be
0.15% one and a half hours after driving, if he was less than 0.08% (and no longer absorbing) when he crashed?

16. If a subject’s BrAC is 0.12%, what would their BrAC be if their correlation ratio was 2400:1? 2000:1? 1000:1? Are these reasonable values to perform the calculation?

17. What would the level of a subject be if they had a correlation ratio of 1500:1 when they blew into the breath instrument and it read 0.11%?

18. If a subject’s BrAC is 0.093%, would they still be above 0.08% if the defense contends that the subject had a correlation ratio of 1800:1 at the time of the breath test?

19. If a subject had a blood alcohol level of 0.08%, what would their breath alcohol level be if their correlation ratio at that time was 1600:1?

20. If a person has blood and breath taken at the same time (BAC = 0.14% and a BrAC = 0.11%), what would their correlation ratio be?

D. Assessment

1. Trainer, or designee, will review and assess the answers provided by the trainee for the study questions and practical exercises. Written feedback will be provided to the trainee.

E. Documentation

1. Answers to the study questions/practical exercises must be submitted to the trainer, or designee, for review.

2. The trainer or designee will review and provide written feedback (signed and dated) and the trainee will include this documentation in their training binder.

V. Module 4: Field Sobriety Tests and Evaluation - (Duration ~1 month)

A. Objectives/Topics of Study

1. Validations

2. Principles, Application, and Evaluation

3. Standardized FST's vs. FST's

4. Law enforcement Ride-Alongs/DUI Checkpoints

B. References

1. 1997, Florida Field Validation Study

2. 1998, California Field Validation Study

3. Field Sobriety Test Are They Designed for Failure? (ALCO.082)

4. NHTSA and FSTS True Lies and False Advertising (ALCO.83)

5. Development and Field Test of Psychophysical Tests for DWI Arrest (ALCO.081)
6. Colorado Validation Study of the Standardized Field Sobriety Test (SFST) Battery (ALCO.084)

7. An Overview of Field Sobriety Test Research (ALCO.085)

8. Gaze Nystagmus As a Roadside Sobriety Test (ALCO.100)

9. Use of Horizontal Gaze Nystagmus as a Part of Roadside Sobriety Testing (ALCO.089)

10. Is the Driver Drunk? Oculomotor Sobriety Testing (ALCO.090)

11. Horizontal Gaze Nystagmus The Controversy and the Issues (ALCO.093)

12. Gaze Nystagmus and Blood Alcohol (ALCO.088)

13. The Horizontal Gaze Nystagmus Test Fraudulent Science in the American Courts (ALCO.096)

15. DRE Handbook

C. Study Questions/Practical Exercises

1. Define FST's.

2. What does standardized mean?

3. Which FST's are the Standardized FST's?

4. What are the validated clues for each of the Standardized FST's?

5. Are the clues/evaluation for SFST's objective or subjective? Explain.

6. Describe the training that you've received for SFST's clues and administering SFST's.

7. Does a person pass or fail FST's? How are FST's evaluated?

8. During the WAT validation study, how many clues were deemed necessary to determine that the individual was over 0.10%?

9. During the OLS validation study, how many clues were deemed necessary to determine that the individual was over 0.10%?

10. During the HGN validation study, how many clues were deemed necessary to determine that the individual was over 0.10%?

11. Would you draw a conclusion about impairment from one FST without a chemical test?

12. Would you draw a conclusion about impairment from all three SFST's without a chemical test?

13. Are non-SFST's a useful tool for an officer when deciding whether or not a subject is too impaired to drive? Why?

14. Practical Exercise: Participate in at least two Ride-Alongs with law enforcement. Ride-Alongs with law enforcement allow the analyst to observe driving patterns,
objective signs and symptoms, and field sobriety testing of subjects suspected of driving under the influence of alcohol and/or drugs in the field. It is recommended to request a Ride-Along with a DUI Enforcement officer. Prepare a summary of observations.

15. Practical Exercise: Attend DUI Checkpoint with a trainer, or designee, to observe the process of breath instrument installation and removal. DUI Checkpoints are also an opportunity for an analyst to observe officers using FST's to evaluate drivers suspected of being under the influence of alcohol and/or drugs. Prepare a summary of observations.

D. Assessment

1. Trainer, or designee, will review and assess the answers provided by the trainee for the study questions and practical exercises. Written feedback will be provided to the trainee.

E. Documentation

1. Answers to the study questions/practical exercises must be submitted to the trainer, or designee, for review.

2. The trainer or designee will review and provide written feedback (signed and dated) and the trainee will include this documentation in their training binder.

VI. Module 5: Non-Driving Issues - (Duration ~1 month)

A. Objectives/Topics of Study

1. Black-outs

2. Gastroesophageal Reflux Disease (GERD)

3. Diabetes

4. Gastric Bypass

5. Chronic Obstructive Pulmonary Disease (COPD)

6. Asthma

7. Body/Breath Temperature

8. Lung Volume/Body Size

B. References

1. Alcoholic Ketoacidosis (ALCO.026)

2. APRI - Alcohol Toxicology for Prosecutors

4. Effect of Low Doses of Alcohol on Driving-Related Skills. (ALCO.066)

5. Faster Absorption of Ethanol and Higher Peak Concentration in Women After Gastric Bypass Surgery, H. Klockoff, I Naslund, & A.W. Jones
6. Does Gastric Bypass Alter Alcohol Metabolism? Surgery for Obesity and Related Diseases; 2007, Sep-Oct; Vol 3 (Issue 5)

7. Perspective: Alcohol and the Gastric Bypass Patient; Cynthia K Buffington, PhD, Bariatric TimesVolume 3, Issue 8, Oct 2006

9. Breath Alcohol Analysis in One Subject with Gastroesophageal Reflux Disease; Gullberg, RG, Journal of Forensic Science, 2001, 46(6)

11. Are Women at Greater Risk? An Examination of Alcohol-Related Consequences and Gender; Dawn E Sugearman, Kelly S. DeMartini, Kate B. Carey, Am J Addict, 2009; 18(3)

C. Study Questions/Practical Exercises

1. Does alcohol affect short-term or long term memory?

2. What is a Black-out?

3. What conditions are more likely to cause a Black-out?

4. What is GERD?

5. Is GERD a viable defense for a blood alcohol case? For breath alcohol case? Why?

6. What are the signs and symptoms of a person that is experiencing a diabetic episode? How does that relate to impairment?

7. What blood alcohol results would you expect to see for a person's whose defense is a diabetic episode?

8. How is the breath alcohol concentration affected when someone has an elevated body temperature?

D. Assessment
1. Trainer, or designee, will review and assess the answers provided by the trainee for the study questions and practical exercises. Written feedback will be provided to the trainee.

E. Documentation

1. Answers to the study questions/practical exercises must be submitted to the trainer, or designee, for review.

2. The trainer or designee will review and provide written feedback (signed and dated) and the trainee will include this documentation in their training binder.

VII. Module 4: Legal/Ethics - (Duration ~1 month)

A. Objectives/Topics of Study

1. The Legal Framework for DUI - Constitutional Issues and Case Law

2. General Forensics -
   a. Review of laboratory procedures
   b. Review of general forensic textbooks

3. Analyst role as custodian of records
   a. Providing testimony for another analyst
   b. Laboratory records

4. Response to Defense Challenges in Forensic Alcohol Testing

5. Expert Testimony: Basic Principles
   a. Scope of Expertise
   b. Testify to facts presented in court
   c. Presentation of evidence
      i. Biological sample/evidence envelope
      ii. Analytical results
         1. Fluid analysis
         2. Breath analysis

B. References

1. Competency, Training, Authorizations & Ethics (FSD.21)

2. QA and Ethics Training (Powerpoint in PowerDMS)

C. Study Questions/Practical Exercises

1. What is a 115?

2. What is a business record?
3. What is a prelim?
4. What is a 402 hearing?
5. Does the Laboratory only analyze cases in anticipation of court? Why?
6. What is the purpose of your courtroom testimony?
7. What should you do if you realize you made an error in your testimony?
8. What does it mean to be a custodian of records for this Laboratory?
9. In general, how is evidence processed in other disciplines: DNA, Latent prints, Firearms, Seized Drugs?
10. Discuss the role of the following in a trial: Expert witness, judge, prosecution, defense counsel, defendant, bailiff, & jury.
11. Define the following: voir dire, direct examination, cross examination, redirect, rebuttal witness, discovery, subpoena, SDT, deposition, and chain of custody.

D. Assessment
   1. Trainer, or designee, will review and assess the answers provided by the trainee for the study questions and practical exercises. Written feedback will be provided to the trainee.

E. Documentation
   1. Answers to the study questions/practical exercises must be submitted to the trainer, or designee, for review.
   2. The trainer or designee will review and provide written feedback (signed and dated) and the trainee will include this documentation in their training binder.

VIII. Module 7: Mock Court - (Duration ~1 month)

A. Objectives/Topics of Study
   1. The trainee will be familiar with the line of questioning from the prosecution and the defense.
   2. The trainee will be familiar with proper etiquette while in the courtroom.
   3. The trainee will perform a practical exercise for courtroom testimony that will test the analyst's knowledge, skills, and abilities in being able to be a present evidence in a courtroom setting and provide their expert opinion.
   4. The trainee will be able to articulate the knowledge in this Alcohol Impairment Training procedure.
   5. Interpretation of results of alcohol analysis, including correlation of alcohol analyses with subjective observations of the demeanor and behavior of persons who have ingested known amounts of alcohol.

B. References
   1. Title 17
2. APRI - Alcohol Toxicology For Prosecutors
3. Expert Witness and Communications Competency (ALCO.110)
4. Preparing Witnesses for cross-Examination (ALCO.112)
5. The Technical Presentation (ALCO.113)
6. Tips for Technical Talks (ALCO.114)
7. Nonverbal Communication in the Courtroom (ALCO.116)

C. Study Questions/Practical Exercises

1. Become familiar with the common questions asked for alcohol impairment cases. Write your own answers to these common questions asked of an expert witness.

2. Become familiar with the common defense tactics that are encountered on blood alcohol and breath alcohol cases such as: fermentation, hemolysis, contamination, alcoholic swab to clean arm, salting out, GERD, mouth alcohol, elevated breath alcohol with fever, breath instrument not calibrated properly, etc.

D. Assessment

1. Trainer, or designee, will review and assess the answers provided by the trainee for the study questions and practical exercises. Written feedback will be provided to the trainee.

2. The final assessment of the trainee will be determined by the successful completion of a written test and a mock court.

3. Upon successful completion of BRA.17, BA.41, and both the written test and the mock court, the trainee will be authorized as an FAA by the laboratory and deemed capable of testifying in court on alcohol impairment cases.

   a. Title 17 Written Test:

      i. A written test will be completed by the trainee to assess the knowledge, skills, and abilities acquired by the trainee after completing all modules within the Alcohol Impairment Training procedures.

      ii. The trainee must pass the test with a minimum of 80 out of 100%.

      iii. If the trainee completes the written test satisfactorily, they will progress to the mock court assessment.

      iv. If the trainee completes the written test unsatisfactorily, remedial training will occur at the discretion of the Supervisor/Manager. Remedial training will be documented with a QA Action.

   b. Mock Court:

      i. A practical exercise for courtroom testimony will be completed by the trainee such as a mock court.

      ii. The prosecution and defense counsel will be two experienced analysts qualified as FAA's by the laboratory.
iii. The two analysts assigned as the prosecution and the defense counsel will also act as the assessors determining the satisfactory or unsatisfactory completion of the mock court.

iv. Oral feedback will be provided to the trainee at the end of the mock court.

v. The Supervisor/Manager will be notified of the satisfactory or unsatisfactory completion of the trainee's mock court.

vi. Written feedback will be provided to the trainee after the completion of the mock court.

vii. If satisfactory completion of the mock court was determined by the mock court assessors the trainee will be authorized as an FAA by the laboratory, providing the Title 17 requirements have been met.

viii. If the performance of the trainee's mock court was unsatisfactory, remedial training will occur at the discretion of the Supervisor/Manager. Remedial training will be documented with a QA Action.

E. Documentation

1. Answers to the study questions/practical exercises must be submitted to the trainer, or designee, for review.

2. The trainer or designee will review and provide written feedback (signed and dated) and the trainee will include this documentation in their training binder.

3. Assessors written feedback of the trainee's written test, mock court performance, and any remedial training will be kept in the analyst's training binder.

END OF DOCUMENT
I. Policy: The administration of breath tests to determine breath alcohol levels is performed by trained operators of the various client agencies having jurisdiction within Contra Costa County. The Forensic Services Division oversees the breath-testing program and provides training to the client personnel.

A. The breath alcohol instruments in Contra Costa County analyze breath samples by infrared spectroscopy and electrochemical fuel cell technologies.

B. The California State Department of Public Health (CDPH) regulates forensic blood alcohol analysis and forensic breath alcohol analysis according to the pertinent Code of Regulations listed below:

1. Title 17. Forensic Alcohol Analysis
   a. Group 8. Forensic Alcohol Analysis and Breath Alcohol Analysis
   b. Articles 1-8

2. The Laboratory must adhere to Title 17. Some of the requirements the laboratory must meet include:
   a. qualifications of the analysts
   b. quality control program
   c. proficiency testing
   d. collection and handling of samples
   e. standards of performance
   f. standards of procedure

3. A copy of Title 17 is located on PowerDMS.

4. The Breath Alcohol Technical Unit Manual is designed to supplement the Title 17 requirements.

5. Prior to April 1, 2017, the California State Department of Public Health (Title 17) qualified analysts working in a Forensic Alcohol Laboratory as one of the following: a Forensic Alcohol Supervisor (FAS), a Forensic Alcohol Analyst (FAA), or a Forensic Alcohol Analyst Trainee (FAAT). As of April 1, 2017, it is the responsibility of each Forensic Alcohol Laboratory to authorize their personnel to perform duties in accordance with qualifications outlined in Title 17.
C. Terminology

1. The verbs "shall", "must", and "will" indicate mandatory requirements, while "should" is used to denote compelling or recommended practices and "may" is used in the permissive sense.

D. Methods

1. All instructions, standards, manuals, and reference data relevant to the work of the Forensic Alcohol Unit shall be kept up to date and made readily available to personnel through the use of this Technical Unit Manual.

2. All methods shall be documented and the documents readily available for review by laboratory personnel through PowerDMS (see the Division Manual for more information).

END OF DOCUMENT
I. Policy: The following are general breath test requirements.

A. Breath tests on subjects are performed on the Intoximeters, Inc., Intox-DMT Dual Sensor as described under Breath Test Operator Training-General and Operator Training Course Outline documents.

B. Only personnel trained and certified by the Laboratory are authorized to administer a subject breath test.

C. Operators shall adhere to the precautionary checklist for the instrument operated.

D. A breath sample is collected only after the subject has been under continuous observation for at least 15 minutes prior to collection of the breath sample, during which time the subject must not have ingested alcoholic beverages or other fluids, regurgitated, vomited, eaten, or smoked.

E. Breath is expired into the instrument until a sample of essentially alveolar air has been collected.

F. For each person tested, breath alcohol analysis shall include the analysis of at least two separate breath samples which result in determination of breath alcohol concentrations which do not differ by more than 0.020 g/210L.

G. For each person tested, a valid subject breath test shall include duplicate analysis of an external standard.

1. The purpose of the external standard check is to ensure accurate and reliable results at the time of the subject breath test.
   a. The external standard check must be within +/- 0.010 g/210L of the nominal value.
   b. The Intox-DMT will remove itself from service if the external standard check is unacceptable. The instrument will not be able to be used until it has been evaluated by Lab staff.

2. The external standard analysis during a subject breath test does not replace a Periodic Determination of Accuracy, a Tank Change, or an Accuracy Check.

H. The units of breath alcohol concentration in these procedures are grams of alcohol per 210 L of breath (W/V).
1. When using the Intox-DMT, the reported analytical breath alcohol results are averaged and truncated to the third decimal place.

2. Breath alcohol concentrations less than 0.01 g/210L from test subjects will be reported as negative.

3. The Intoximeters, Inc., Intox-DMT Dual Sensor instrument measures the breath alcohol concentration of a subject, reporting the results in grams of alcohol per 210 L of breath. Per the California Vehicle Code, Section 23152(b), "percent, by weight, of alcohol in a person's blood is based upon grams of alcohol per 100 ml of blood or grams of alcohol per 210 L of breath."

I. Infrared and fuel cell results will be flagged as IR-FC Disagreement (Intox-DMT) if the following criteria are not met:

1. For results below 0.08 g/210L, there must be an agreement between the infrared and fuel cell results of +/- 0.008.

2. For results above 0.08 g/210L, there must be an agreement between the infrared and fuel cell results of 10%.

J. The following criteria for the Intox-DMT Dual Sensor must be met to have a valid result:

1. Interference will be triggered by a disagreement between filters 1 and 2, or filters 1 and 3, for a sample. The filter agreement threshold will be a percentage of the sample concentration measured at filter 1 down to a minimum value of 0.005 g/210L. For wet bath solutions and breath samples the agreement percentage is 4%. For dry gas standards the agreement is 5%. This means that during an adjustment, when a known ethanol concentration is introduced, the instrument records how it is perceived at all three filters. If a breath sample is measured as a 0.193 at filter 1, the instrument compares the reading to the values at filters 2 and 3. If the values are comparable at all three filters based on the last calibration, the measurement is valid. If either of the values (difference at filter 2 or difference at filter 3, as seen in parenthesis on the "View Test Details" report) are more than 4% of the 0.193, it will be flagged as interference. Similarly, if a dry gas is read as an 0.099, and the difference at filter 2 or filter 3 is more than 5% of an 0.099, it will be flagged as an interference.

2. Additionally, there is a combinational check, where the sum of the differences at filter 2 and filter 3 is 7/5 of the filter agreement threshold. If a breath sample is measured as an 0.193 at filter 1, the instrument will compare the value to filters 2 and 3 (as described above). It could be that neither of the readings are outside of the 4%. If the difference at filter 2 is 0.006 and the difference at filter 3 is 0.005, then together they are 0.011. 7/5 * 5% of 0.193 is 0.0135. This situation will not flag interference.

3. A calculation is done by the instrument's software to offset how a dry gas is perceived at filter 3, based on the initial adjustment having been done using a wet bath solution. This compensation for the dry gas value means the instrument is less likely to erroneously flag interference from the difference at filter 3.

K. Each of the following minimum criteria must be met for a valid breath sample on each instrument:

1. Intox-DMT Dual Sensor breath instrument:
   a. Minimum Flow Rate: 3.0 L/min.
b. Minimum Breath Volume: 1.5 L.

c. The slope of the alcohol concentration curve must meet the following criteria at the point when the flow rate drops back below 3 L/min. after having met the 1.5 L total volume requirement:

   i. The increase from the second to last 2 point average to the last (at the time the flow rate drops below 3 L/min.) must be less than or equal to 0.001 g/210 L and not a negative slope. In order to be considered a negative slope, the change in consecutively compared averages must be greater than 0.001 in the negative direction.

   ii. Therefore, in order to be a slope that will allow a sample to be accepted, the absolute value of the change between the final two 2 point averages must be 0.001 g/210 L or less.

END OF DOCUMENT
I. Policy: The following is general information for breath alcohol analysis records.

A. The Laboratory shall maintain Breath Alcohol Analysis records for at least five years over an accreditation cycle. The records will be arranged as prescribed below. All official Breath Analysis records shall be maintained and located in such a manner that they will be immediately available (upon request) for inspection by representatives of the California Department of Public Health.

B. All information that is generated by entry into the Intox-DMT Dual Sensor breath alcohol instrument will be uploaded to a Secure File Transfer Protocol site (SFTP) and transferred to the DMHost database. The data is uploaded to the Laboratory's database from DMHost. Periodic Determinations of Accuracy, Subject Test Logs, and Maintenance Logs will be generated as needed from the Laboratory's database. The database will be backed up periodically by Technical Services.

C. Breath alcohol analysis records, or copies thereof, shall not be released to any unauthorized agency or person without a properly executed court order, authorization of the prosecuting attorney, or specific authorization from the Chief or Forensic Manager of the Laboratory. Refer to BRA.15 Breath Alcohol Discoveries for procedures for generating discovery documents.

D. Certified Laboratory Personnel

1. The Laboratory will maintain a record of qualified Forensic Alcohol Analysts as required in Title 17, Section 1222.1.

E. Instrument Records, Subject Related Records, and Operator Training Records

1. Instrument File:
   a. The Laboratory shall maintain an instrument file for each breath alcohol instrument.
   b. The instrument file contains records such as packing slips, calibration certificates, and letter correspondence. The records may be imaged and stored electronically in the alcohol unit.
   c. Any information in the instrument file should be referenced in the maintenance log.

2. Maintenance Log:
   a. The Laboratory shall maintain a maintenance log for each breath alcohol instrument.
   b. For each instrument the following will be recorded electronically in the maintenance log of the Database:
      i. description of activity
      ii. date and time
      iii. location
      iv. analyst performing the maintenance
   c. Transactions entered include, but are not limited to:
      i. installation and removal at field sites
      ii. instrument calibration
      iii. linearity checks
      iv. instrument repair/maintenance
4. **Determination of Accuracy Records:**

   a. The Laboratory shall maintain a record for each determination of accuracy performed (PDOA) on an instrument that is installed at a field location. The data is stored in the memory of the instrument until it is uploaded to the Laboratory database. The data will include:

   i. Instrument Serial Number
   ii. Test Type
   iii. Test Date and Time
   iv. Type of reference used (Dry Gas or Simulator Solution)
   v. Concentration of reference solution
   vi. Name of person performing/reviewing the test
   vii. Duplicate test results for the Infrared and Electrochemical Fuel Cell analysis
   viii. Tech Notes - Notes that are added to the database.
5. **Breath Test Operator Records:**
   
a. The Laboratory shall maintain a database of persons trained and certified as breath test operators. This database will contain a minimum of:
   
i. Operators name
   
ii. Agency
   
iii. Date of the training course
   
iv. Name of the instructor.
F. Records kept at all Field Locations
   1. Precautionary Checklist
2. The Laboratory shall supply each instrument location with copies of the Precautionary Checklist. The Precautionary Checklist contains the testing procedure to be used by the operator.

3. The record of all analyses performed, results, and identities of the persons performing the analyses are stored in the memory of the instrument. This information is periodically retrieved with data transfer via modem or network upload to the Laboratory database.

END OF DOCUMENT
I. Policy: The location of breath testing sites is based, in part, on geographical distribution and, in part, on frequency of tests. The Chief of the Forensic Services Division may, with the approval of the Sheriff, discontinue services to a breath testing location if the number of tests performed at that location fails to justify the continued expenditure of Forensic Services Division staff time to service the instrument.

A. Breath Testing Sites

1. Agency Locations with an Intox-DMT Dual Sensor:
   a. Antioch PD
   b. Brentwood PD
   c. CHP-Martinez
   d. Concord PD
   e. Danville PD
   f. El Cerrito PD
   g. Lafayette PD
   h. Martinez DF
   i. Moraga PD
   j. Oakley PD
   k. Orinda PD
   l. Pinole PD
   m. Pittsburg PD
   n. Pleasant Hill PD
   o. Richmond PD
   p. San Pablo PD
   q. San Ramon PD
   r. Walnut Creek PD
s. CCC S/O-Discovery Bay (typically summer season)

2. FOR DUI CHECK POINTS:
   a. DUI CK PT-Agency in charge
      i. Example: DUI CK PT-Antioch PD

3. FOR FOB TRAINING:
   a. Example: Train-FOB Training Room

4. FOR CCC S/O ACADEMY TRAINING:
   a. Example: Train-CCCSO LETC

END OF DOCUMENT
I. Policy: The following are forms used in Forensic Alcohol Analysis. Forms may be controlled (required for use) or non-controlled (suggested for use but not required).

A. Controlled forms are located on PowerDMS and must be used.
   1. Calibration Check Variable Pipette (controlled) ALC.17
   2. Solution Monthly Check Log (controlled) ALC.14

B. Non-controlled forms are located on PowerDMS. The minimum information that must appear on the form is listed below.
   1. Calibration Check Bench Notes ALC.11
      a. Date
      b. Analyst
      c. Equipment Identification
      d. Thermometer serial # and reading
      e. Weights of water
   2. Balance Maintenance Log ALC.05
      a. Date
      b. Problem or symptom
      c. Action taken
      d. Analyst
   3. Balance Calibration Check Log ALC.06
      a. Date
      b. Analyst
      c. Results of check
   4. Pipette Maintenance Log ALC.24
      a. Date
b. Problem or symptom
c. Action taken
d. Analyst

5. Thermometer Maintenance Log ALC.28
   a. Date
   b. Problem or symptom
c. Action taken
d. Analyst

6. Barometer Maintenance Log ALC.20
   a. Date
   b. Problem or symptom
c. Action taken
d. Analyst

7. Alcohol Discovery/OLA Billing Sheet ALC.38
   a. Charge and type of discovery
   b. Charge for evidence transfer (OLA)
c. Subject's name
d. Lab # (if applicable)
e. Analyst
f. Date

8. Intox-DMT Dual Sensor Installation Checklist ALC.40
   a. Documentation of the steps taken to correctly install an instrument

9. Intox-DMT Dual Sensor Removal Checklist ALC.41
   a. Documentation of the steps taken to correctly remove an instrument from service

10. Intox-DMT Service Checklist ALC.42
    a. Documentation of the steps taken to verify the instrument adequately meets the Lab's criteria before an instrument may be installed into service.

11. Intox-DMT Dual Sensor Adjustment Worksheet ALC.43
    a. Documentation of the steps done to make an adjustment on the Intox-DMT.

END OF DOCUMENT
I. Policy: The following are the general requirements for periodic determinations of accuracy (PDOA) on the breath instrument.

A. Breath alcohol instruments listed in the Laboratory procedure are maintained by Qualified Laboratory Personnel.
   1. The PDOA checks are performed at least every 10 days or following the testing of 150 subjects, whichever comes sooner.
   2. Each instrument is programmed to disable after 150 subject tests if a PDOA check is not performed.
   3. PDOA's shall be conducted in duplicate using reference samples of known alcohol concentration, these samples are provided by a wet-bath simulator or a NIST traceable dry gas cylinder.
   4. The concentration of the reference solutions for PDOA's will be from 0.080 g/210 L to 0.300 g/210 L BrAE.

B. The PDOA's are performed automatically and the results are reviewed by a Laboratory authorized analyst.
   1. Each instrument installed for use at an agency is programmed to perform the PDOA weekly (example: every Tuesday morning at 6:00 am).

C. The results for each PDOA are recorded to four decimal places and must be within +0.010 g/210 L of the known value of the reference concentration.
   1. If any of the four results (duplicate IR and FC) is not within ±0.010 g/210 L of the known value, the instrument will disable itself. The instrument will not function until it is serviced by a qualified laboratory member and passes a PDOA check.

D. The results of the PDOA are stored in the memory of the instrument until they are uploaded to the laboratory computer.
   1. The results are evaluated by a Laboratory authorized analyst after the data retrieval.
   2. The data from each test done will be downloaded to the Laboratory's SFTP server.
   3. The results of the PDOA will be reviewed the same day, or near the time of the test, by qualified laboratory personnel.
4. The results of these tests will be stored in the computer database in the Accuracy Check Log.

E. The dry gas cylinders and reference solutions of known alcohol concentration will be transported to the instrument sites and installed by qualified laboratory personnel.

1. The dry gas cylinders will be replaced prior to the expiration date marked on the cylinder or when it is empty, whichever comes first.

2. The wet bath reference solutions will be replaced after 5 weeks or after 15 duplicate tests, whichever comes first.

3. Each time a reference solution or a dry-gas cylinder is replaced it is noted in the Accuracy Check Log as a Tank Change.

4. Each time a new dry-gas cylinder or reference solution is installed the known BrAE value is programmed into the instrument.

II. Policy: The following are the procedures for periodic determinations of accuracy on the breath instrument. The following procedure is performed by qualified personnel.

A. DISTRIBUTION OF SOLUTIONS:

1. If a wet bath reference solution is used, it is brought to the location on the first full week of the month. If a dry gas reference solution is used, it will be replaced when empty or by expiration date, whichever occurs first.

2. The analyst will perform a Tank Change. The Tank Change function will save the lot number, expiration date, simulator serial number (if applicable), and concentration of the reference standard installed in the instrument.

B. FUNCTION SETTINGS when using the Intox-DMT -Dual Sensor:

1. The PDOA is automatically performed by the instrument. The instrument function settings for the accuracy configuration and the automatic accuracy checks are described in Function Settings and is repeated below:

   a. Tap the main menu on the home screen of the Intox-DMT

      i. choose Set Up

      ii. choose PDOA Test

         1. Test Day of Week: Tuesday

         2. Test Hour: 6

         3. Number of Weeks Valid: 1

         4. Number of Tests Valid: 150

      iii. click Save and Exit from the set up menu

      iv. The instrument uses the information stored for the dry gas standard or wet bath reference solution from the most recent Tank Change.

C. DATA RETRIEVAL:

1. The Intox DMT will send results to the SFTP server immediately after any test. All tests will be uploaded from the SFTP server when DMHost software is opened.
D. REVIEW OF RESULTS OF THE WEEKLY PERIODIC DETERMINATION OF ACCURACY

1. The PDOA will be performed by the instrument according to the PDOA settings in the Main Menu.

2. The Intox DMT will perform the PDOA and store the information in the memory of the instrument. If the PDOA does not pass, the instrument is programmed to immediately disable itself. The Intox-DMT will send the data via network transfer to the SFTP server to be viewed by an analyst in the DMHost software.

3. The laboratory computer will be on 24 hours a day to receive messages from the instruments in the field. The Laboratory authorized analyst shall check the computer screen at least weekly to ensure a timely response to any instrument problems. Operators are instructed to use another agency's breath instrument or the obtain urine or blood for alcohol testing, when any agency instrument is disabled.

4. A qualified analyst of the laboratory will check the PDOA results for any disabled instruments that are displayed and respond accordingly.

5. A qualified analyst will check the results of the PDOA by entering their name in the table listing the results of the automatic PDOA in the following procedure:
   a. Intox-DMT:
      i. Click on the DMHost.exe Icon on the desktop
      ii. Answer question: Do you want to transfer tests from SFTP? Click YES and wait for upload of data
      iii. Click on the listed item titled RECORDS to expand the list
      iv. Double-click on the PDOA item in the list under RECORDS
      v. When the PDOA window opens, check the setting APPROVAL NEEDED box
      vi. Click on the APPLY FILTERS icon
      vii. Double-click on the record row to be reviewed
      viii. When the details window opens, review the following:
          1. Test date, Location, Nominal & Target (concentrations), Expiration date. (look for discrepancies)
          2. In the Test Results inner window, check to determine if the Alcohol IR and FC results are within 0.010%
          3. Click on whether results are APPROVED or NOT APPROVED
          4. Enter the initial of the analyst's First Name
          5. Enter the analyst's Last Name
          6. Click icon to CONFIRM
          7. Click [X] to exit the record
          8. Click on the next record row of PDOA data to be reviewed and complete steps When all PDOA's have been reviewed, click on
the disk icon (Save button).

9. Click [X] on the inner window to exit the PDOA records window.

END OF DOCUMENT
I. Policy: Reference Solutions are aqueous solutions of known alcohol concentration. The reference solutions are used to check the accuracy of breath testing instruments.

A. Chemicals used for Reference Solution Preparation
   1. Refer to the Blood Alcohol Technical Unit Manual (BA.03)
   2. An entry is made in the Alcohol Tracking Database for each new solution prepared. Refer to BA.44.

B. Equipment Required for Reference Solution Preparation and Analysis
   1. Refer to the Blood Alcohol Technical Unit Manual
   2. Variable pipette
   3. Graduated cylinder
   4. Volumetric flask
   5. Nalgene carboy
   6. Dual column gas chromatograph-flame ionization detector (DCGC-FID)
   7. Breath testing instrument
   8. Simulator(s)
      a. For example: Guth Models 34C and 2100 Simulators
   9. Ethanol dry gas canisters
   10. Dry gas regulators

C. Care and Maintenance of Equipment
   1. Refer to the Blood Alcohol Technical Unit Manual (BA.21)

D. Verification of Purity of U.S.P. Absolute Ethanol
   1. Refer to the Blood Alcohol Technical Unit Manual

E. Preparation of Reference Solutions of Known Alcohol Concentration
   1. DILUTION TABLE

</tbody>
</table>

Example: To prepare 6 gallons of a 0.1579% BrAE reference solution: Following the above dilution table, partially fill a large plastic carboy (*Nalgene*) container marked at a volume of 6 gallons with distilled or de-ionized water. Using a graduated cylinder deliver 55 ml of purity checked or NIST traceable absolute ethanol. Bring to volume with distilled or de-ionized water and mix well. The solution should be allowed time to equilibrate before establishing the concentration.

2. A Reference Solution can be made quantitatively if a calibrated flask, calibrated pipette, and an NTRM ethanol is used. The above Dilution Table may still be utilized.

3. Enter the solution preparation in the Alcohol Tracking Database. See [BA.44](#).

4. Label the bottle with the Solution ID, Breath Alcohol Equivalent (BrAE) at 34.0°C, date prepared, initials of analyst, and date to be discarded. The reference solution ID will start with R, and is followed by the date prepared (YYMMDD) and the four digit value reflecting the BrAE of the reference solution. Example: The solution ID for a reference solution prepared on October 25, 2016 with a BrAE of 0.1246% would be R1610251246.

5. The shelf life of reference solutions is two years and it will be stored at room temperature.

F. Establishment and Analysis of Ethanol Reference Solutions

1. The concentration of Reference Solutions that are not made quantitatively are established by analysis using DCGC-FID.
   a. Analyze the Reference Solution six times (in duplicate) such that there will be twelve replicate sample (aliquots) results. Three times (six replicates) on each DCGC-FID instrument available, if possible. Refer to [BA.30](#) for analysis using the DCGC-FID.
   b. Enter the DCGC values in the Reference Solution Establishment Form ([ALC.31](#)). The completed Reference Solution Establishment Form should be maintained in the Alcohol Unit and linked to the solution in the Alcohol Tracking Database ([BA.44](#)).
   c. Monthly checks will be performed by Heated Headspace Dual Column Gas Chromatography (done in duplicate). Use [ALC.14](#) to record the monthly...
check. The completed form is maintained in the Alcohol Unit. The results will not differ by more than 5% of the of the known concentration. If the results are outside 5%, the solution will be discarded.

2. The concentration of the Reference Solution is converted to a Breath Alcohol Equivalent (BrAE) by adjusting for the conversion factor as found in references provided by experimental data in work originally done by Harger, Raney, Brindwell, and Kitchell, _The Partition Ratio of Alcohol Between Air and Water, Urine and Blood; Estimation and Identification of Alcohol in these Liquids from Analysis of Air Equilibrated With Them_, J. Biol. Chem., 183, 1950; 197-213.

   a. The breath alcohol equivalent (BrAE) is the value obtained when air equilibrated with the reference solution in a simulator is analyzed with a properly calibrated breath alcohol analysis instrument.

   b. The calculations in Harger's original work were not specific to breath alcohol and therefore did not have a specified conversion value at 34 degrees Celsius which is crucial for breath alcohol analysis.

3. Subsequent work done by R. G. Gullberg addresses the need for a better approximation of the conversion factor at 34.0°C. The laboratory uses the conversion factor of 0.827, which is derived from the dimensionless value recommended by Gullberg (1.21 at 34.0°C), being the best value for forensic purposes (lowest calibration when used for adjustments).

4. The BrAE is calculated by multiplying the conversion factor of 0.827 by the ethanol concentration of the reference solution obtained by GC/FID.

   a. Example 1: For a reference solution of 0.200% and a temperature of 34.0°C:

      i. Conversion factor is 0.827
      ii. BrAE = 0.827 x 0.2000% = 0.1654% at 34.0°C

   b. Example 2: A reference solution of 0.1500% would give the expected instrument reading:

      i. Simulator Temp 34.0°C: Conversion Factor = 0.827
      ii. (0.827) X (0.1500%) = 0.1240 g/210L (BrAE)

G. Usage

1. The reference solutions having a value between 0.10% and 0.20% ethanol may be used for a maximum number of 15 duplicate accuracy checks.

2. The solutions having values at or above 0.200% ethanol may be used for a maximum of six duplicate accuracy checks.

3. Monthly checks will be performed on Reference Solutions by Heated Headspace Dual Column Gas Chromatography (HHDCGC) done in duplicate. A monthly check will be performed on reference solutions. If the results differ by more than 5% from
the known concentration the solution will be discarded. Use ALC.14 to record the monthly check. The completed form, ALC.14, is maintained in the Alcohol Unit.

4. When ready to use, the reference solutions will be dispensed into 500 ml bottles and properly labeled for transport to the instrument sites by qualified laboratory personnel. Each bottle will be labeled with the lot number, date prepared, date of expiration, and initials of analyst.

H. Preparation of Out of Measuring Range Solution

1. This solution is used during breath alcohol instrument maintenance.

2. Prepare an ethanol-water solution at a concentration slightly above the linear range. The ethanol concentration should not be high enough that the analytical system is overwhelmed.

   a. This solution may be prepared by adding 8 mL of ethanol to 1 L of water in 1 L flask (for a ~0.509% BrAE). Solution may be adjusted drop-wise with ethanol as needed.

3. The solutions may be transferred to labeled 500 ml bottles for storage and transport; or placed into labeled simulators for use during breath alcohol maintenance.

4. Each bottle will be labeled with Out of Measuring Range Solution and an expiration date no more than two years from the date of preparation.

I. Preparation of Interference Solutions

1. Interference Solutions are used during breath alcohol instrument maintenance.

2. Prepare the Interference Solutions as follows:

   a. **Interference Table**

<table>
<thead>
<tr>
<th>Interferent</th>
<th>Solution Volumes</th>
</tr>
</thead>
<tbody>
<tr>
<td>Methanol Solution</td>
<td>0.6 ml Methanol</td>
</tr>
<tr>
<td></td>
<td>2 L dH2O</td>
</tr>
<tr>
<td>Acetone Solution</td>
<td>0.6 ml Acetone</td>
</tr>
<tr>
<td></td>
<td>2L dH2O</td>
</tr>
<tr>
<td>Isopropanol Solution</td>
<td>0.6 ml IPA</td>
</tr>
<tr>
<td></td>
<td>2L dH2O</td>
</tr>
</tbody>
</table>

   b. This solution should be made using the volumes in the table above. Solutions may be adjusted drop-wise using the appropriate volatile compound as needed.

3. The solutions may be transferred to labeled 500 ml bottles for storage and transport; or placed into labeled simulators for use during breath alcohol maintenance.

4. Each bottle will be labeled with the interfering substance and an expiration date no more than two years from the date of preparation.

J. Usage

1. Out of Measuring Range and Interference Solutions are not reference solutions and therefore will not be checked monthly. These solutions are not considered quantity critical solutions. Checking these solutions will be at the discretion of the analyst using the solutions as needed.
2. When ready to use, the Out of Measuring Range and Interference solutions will be dispensed into 500 ml bottles and properly labeled for transport to the instrument sites by qualified laboratory personnel.

3. Each bottle will be labeled with the lot number, date prepared, date of expiration, and initials of analyst.

END OF DOCUMENT
I. Policy: Gaseous Ethanol Breath Standards (EBS) are a reference material consisting of a dry mixture of nitrogen gas and ethanol vapor used to deliver a known ethanol concentration to a breath instrument during an accuracy check.

A. Traceability

1. A solution traceable to a National Metrology Institute (NMI), and on the NHTSA Conforming Products List published in the Federal Register, will be used to check the accuracy of evidential breath instruments maintained by the Crime Lab. See FSD.33 for more information about traceability.
   
a. NIST is an example of a NMI.

b. Dry Gas Standard (Ethanol, Balance Nitrogen) manufactured by Mid-America Airgas for Intoximeters, Inc. is an example of a reference solution approved for use with the Intox-DMT Dual Sensor.

2. The laboratory will maintain Certificate of Analysis (COA) traceability records for each lot of dry gas reference material.

B. General Information and Use

1. Intoximeters, Inc. programs the Intox-DMT to use a 4.5% wet/dry offset, therefore, only Uncorrected dry gas standards are to be used.

2. The Intox-DMT is configured with an integrated dry gas compartment that houses a 108 liter dry gas cylinder.

3. The reference material is delivered from an EBS cylinder through a gas flow regulator that provides a flow of 3 liters per minute.

4. The alcohol concentration provided by each EBS cylinder will be between 0.080 to 0.300 grams/210 L at Standard Pressure for the Periodic Determination of Accuracy (PDOA) check.
   
a. Additional accuracy checks may be performed at higher or lower concentrations.

5. Each lot of EBS cylinders is filled with reference material from the same larger container. The cylinders within a lot contain aliquots of a homogeneous nature.

6. EBS cylinders have a shelf life if stored under ambient conditions. The manufacturer marks an expiration date on each EBS cylinder. The EBS cylinders will not be used
past the manufacturer's expiration date.

7. Upon receipt, each EBS cylinder, within a lot, will be identified by the manufacturer's lot number and tank number as identified on the dry gas cylinder.
   
a. For example, if the lot number is AG907710 and the Tank number is 009, it will be identified as AG907710009.

8. Several hundred samples may be obtained from each EBS cylinder. The cylinders will be replaced as needed, this will be prior to the expiration date indicated on the cylinder. Each time an EBS cylinder is changed it will be indicated in the Accuracy Check Log by performing a Tank Change.

9. Each new lot of dry gas standards received into the laboratory should be entered into the alcohol unit tracking database.
   
a. For dry gas standards received from Intoximeters, Inc., a COA is obtained by going to the Intoximeters, Inc. website.
   
i. Click on the Customer Service Tab
   
   1. Click on True-Trace Certificate of Analysis
   
   1. Enter the Lot number, Tank number, DEV Code, then click on Trace My Tank
   
   1. Print the COA to PDF and save in the secure alcohol folder

b. Refer to BA.44 for procedures for linking the COA.

C. Storage

1. Upon receipt, EBS cylinders shall sit overnight in the laboratory to allow each EBS to reach room temperature. Bringing the cylinders to room temperature overnight allows the ethanol and nitrogen to become homogenous within the cylinder.

D. Atmospheric Pressure Compensation

1. Barometric pressure has an effect on the ethanol concentration target values analyzed by the Intox-DMT Dual Sensor when delivered from a compressed gas cylinder. Therefore, a check and adjustment (if necessary) of the instrument's internal barometer are done during regular maintenance.

END OF DOCUMENT
I. Policy: Breath alcohol testing shall be performed with instruments, accessories, calibrating units and devices which meet the requirements specified in Health and Safety Code section 100701. State regulations require that the accuracy and maintenance of breath instruments be checked on a regular basis. Routine accuracy checks and maintenance at the various instrument sites must be performed by the Forensic Services Division per the procedures in accordance with Title 17.

A. For the Intoximeters Inc., Intox-DMT Dual Sensor the routine accuracy and maintenance testing consists of the following:
   1. Instrument Verification and routine service
   2. An Instrument Service Checklist form ALC.42 will be used to document each of the following:
      a. When first received into the Laboratory, any Intox-DMT will have an Instrument Verification to ensure the instrument is functioning properly.
      b. When an instrument returns from service at Intoximeters, Inc.
      c. Every year as a part of a routine annual maintenance check.
      d. When a significant change to the DMT software criteria involved in the analysis of results of subject breath tests, PDOA's, accuracy checks, linearity checks, tank changes, maintenance checks and other software driven instrument checks are done by Intoximeters, Inc.
   3. A forensic alcohol analyst or Laboratory qualified analyst may perform maintenance on the instrument if necessary to satisfy the verification process.
   4. If a Laboratory analyst is not able to correct an issue with an instrument, the instrument may be returned to the manufacturer for necessary maintenance.

B. Refer to the Intoximeters, Inc., Intox-DMT Dual Sensor Contra Costa County Technical Training Workbook for specific instrument parameters and additional information.
   1. The Intox DMT Dual Sensor Technical Training Workbook is provided in the Intox DMT Technical Training Course provided by Intoximeters, Inc. It is provided as a hardcopy binder to students who complete the training course. A copy of the most current workbook will be kept in the Alcohol Unit as a lab reference resource. When any significant changes occur in the breath instrument's hardware/software, Intoximeters, Inc. will be providing a more current workbook documenting those
changes for our lab to keep as a reference. Contact the alcohol unit supervisor if the lab copy is not found within the unit's work area.

2. Intoximeters, Inc. document statement, "Information in this document is subject to change without notice and is intended for use in conjunction with a training lecture by an authorized Factory representative. No part of this document may be reproduced or transmitted in any form or by any means, electronic or mechanical, for any purpose, without the written permission of Intoximeters, Inc. This information is confidential and proprietary."

3. The Laboratory will not copy or distribute Intoximeters, Inc. documentation for any discovery purposes. Any discovery request for this documentation will be rejected and the requestor will be informed of the lab's policy regarding copyrighted materials.

C. Intox-DMT Dual Sensor Instrument Verification process:

1. Unpackage and set-up instrument
   a. Connect all peripheral accessories, including a printer
   b. Turn the instrument on
      i. The instrument is required to warm-up for 2 hours prior to conducting verification tests
      ii. To access the main menu, tap the Intox-DMT button located on the top left corner of the home screen
   c. Install a dry gas canister
   d. Fill a wet bath simulator(s) with reference solution(s) for verification. Turn on and allow for equilibration (approximately 30 minutes).

2. Record the pressure of the dry gas canister on the verification form
   a. The tank pressure is displayed on the bottom right corner of the home screen
   b. A rapid drop in dry gas pressure may indicate a leak in the system

3. Verify the instrument's serial number
   a. Check the electronic serial number on the home screen with the external label on the back of the instrument

4. Verify the the software version loaded on instrument
   a. From the main menu, choose Help, About
      i. Record the software version on the verification form

5. Instrument Function and Parameter setup
   a. Tap on the Intox-DMT menu button located on the top left corner of the home screen. Some functions require a technician password.
      i. Choose Setup (F3)
         1. Update Title to Intox-DMT
2. Update location to CCCSO Lab

2. Choose Units
   1. Set Alcohol to g/210L (grams of ethanol/210 L of breath)
   2. Pressure should be set to mmHg by the factory

3. Choose Simulator
   1. Set Tolerance Check to yes
   2. Set Standard Type to dry
   3. Set Nominal to 0.1000
   4. Set Digital Simulator to None

4. Choose Subject
   1. Set Ask Questions to yes
   2. Set Number of Tests to 2
   3. Set Alcohol Display to no
   4. Set Volume Display to yes
   5. Set Graph Display to no
   6. Set Graph Alcohol to no
   7. Set Graph Flow to no
   8. Set Query Refusal to yes
   9. Set Wait Between Tests to 120
   10. Set Signature On to no
   11. Set Copies to 1
   12. Set Save PDF to yes
   13. Set Simulator Before to no
   14. Set Simulator Between to yes
   15. Set Simulator After to yes
   16. Set Observation Time to 0

5. Choose Accuracy Check
   1. Set Ask Questions to yes
   2. Set Number of Tests to 2
   3. Set Signature On to no
   4. Set Copies to 1
   5. Set Save PDF to yes
6. Choose Tank Change
   1. Set Enable to yes
   2. Set Number of Days Valid to 0
   3. Set Print Graphs to yes
   4. Set Number of Tests Valid to 0
   5. Set Print Graphs to yes
   6. Set Number of Tests to 2
   7. Set Signautre On to no
   8. Set copies to 1
   9. Set Save PDF to yes

7. Choose PDOA Test
   1. Set Test Day of Week to Tuesday
   2. Set Test Hour to 6
   3. Set Number of Weeks Valid to 1
   4. Set Number of Tests Valid to 150

8. Choose Linearity
   1. Set Ask Questions to yes
   2. Set Number of Tests to 3
   3. Set Print each Control Test to no
   4. Set Signature On to no
   5. Set Copies to 1
   6. Set Save PDF to yes

9. Choose Adjustment
   1. Set Ask Questions to yes
   2. Set Standard Type to wet
   3. Set Nominal(Wet Bath) to 0.1000
   4. Set Nominal(Dry Gas) to 0.1000
   5. Set Number of Tests to 3
   6. Set Adj Thru Sim Tube to no
   7. Set Signature On to no
   8. Set Save PDF to yes

10. Choose Diagnostic
1. Set Save PDF to yes

11. Choose Printer
   1. Set Printer On to yes
   2. Set Print in Color to no
   3. Set Printer name to HP PCL5

12. Choose Internet
   1. Set Hour to Connect to 1
   2. Set SFTP Enabled to yes
   3. Set SFTP Address
      1. When in the Lab: 10.212.248.18
      2. When installed at an Agency: 63.192.159.75
   4. Set SFTP Port to 22
   5. Set SFTP User Name to sftp_dmt (case sensitive)
   6. Set SFTP Password
   7. Set Time Server to time.nist.gov

13. Choose Hardware
   1. Set Dry Gas Enabled to yes
   2. Set Tank Pressure Enabled to yes
   3. Set Gas Valve 2 Enabled to no
   4. Set Modem Enabled to yes
   5. Set Heated Sim Hose to yes

14. Choose Software Configuration
   1. Set Use altitude to yes
   2. Set Operator Card Reader Enabled to yes

15. Choose Control Panel
   1. Double click Stylus to recalibrate the touch screen if necessary
   2. Double click Time Zone to verify the date and time and time zone
      1. Time Zone: Pacific Time
      2. Select the box to Automatically adjust clock for daylight saving
      3. Apply before exiting screen
1. If any changes/updates are made, the instrument will need to be restarted to take effect

6. From the main menu, choose Technician Mode (F7)
   1. Set the Radio Frequency Sensitivity
      1. Locate the RF Sensitivity at the top left portion of the screen
      2. Open the graph of the IR Plot by clicking on the "PLOT" tab
         1. Using a hand held radio attempt to trigger RFI by depressing the button to communicate on the radio
            1. Watch for fluctuations on the IR plot on the graph
            2. Watch for fluctuations of the Flow and Detector Voltages
         2. Adjust the sensitivity if there are fluctuations to the IR plot or the voltages are affected
            1. Tap the Set button
               1. Adjust with the + or - button
                  1. (-) Will make the instrument less sensitive
                  2. (+) Will make the instrument more sensitive
      2. Verify the Barometer reading
         1. Check the instrument's Barometer reading in mmHG against the NIST Barometer, adjust if necessary
         2. Record the instrument's barometer reading on the verification form
   3. Verify that the suction switches between the breath tube and the sim tubes
      1. Turn on the Pump
         1. Cycle the Sim Valve open and closed at least 5 times
         2. Check the suction of the tubes by placing your hand over the tube opening
   4. Refer to the Intoximeters, Inc., Intox-DMT Dual Sensor Contra Costa County Technical Training Workbook for specific instrument parameters and settings

7. Perform a Filter Test
   1. From the main menu, choose Functions, Filter Test
      1. Run at least 15 cycles
      2. Record the number of cycles and errors

8. Perform a Diagnostic Test (F4)
   a. When the Diagnostic Test is selected, the instrument will automatically begin a series of self tests.
i. Refer to the Intox-DMT Technical Workbook for acceptable parameter settings.

b. The Diagnostic Test is a check of the following instrument parameters:
   i. Software/firmware/programming versions
   ii. Temperature for sample chamber and breath hose
   iii. Settings for:
       1. Lamp voltage
       2. Cooler voltage
       3. Bias voltage
       4. Chopper frequency
       5. Barometer
   iv. Flow rate of the pump
   v. Detector information
   vi. Filter readings
   vii. Internal standard check
   viii. A copy of the record will print when it is complete
        1. keep a copy with the verification form

c. If any of the self tests result in a "Fail," refer to the Intox-DMT Technical Workbook for troubleshooting.

9. External Standard/Accuracy Checks
   
a. Wet Bath
   i. Perform an Accuracy Check
      1. Use an ethanol/water simulator solution in a value between 0.200-0.300 g/210L
      2. If using a digital simulator, update the Simulator setting in the Main Menu to "Guth."
         1. Connect the digital simulator to the Intox-DMT using the RS232 cable.
         2. Keep a copy of the Accuracy Check printout with the verification form

b. Dry Gas
   i. Perform a series of Accuracy Checks
      1. Check the accuracy of the instrument over a linear range
      2. Keep a copy of the Accuracy Check printout with the verification form
c. If the results of the Accuracy Checks are outside of the acceptable limits, perform an Adjustment
   a. See below for Adjustment Procedures

10. Maintenance Test
   1. The purpose of the Maintenance Test is to trigger errors on the instrument to ensure the safeguards put in place for a proper breath test are functioning properly.
      1. From the main menu choose Maintenance Test
         1. Purge Error: cover the breath hose to stop the flow of air into the instrument during the purge cycle
         2. Incomplete Sample: when prompted, do not provide a breath sample into the instrument
         3. Ambient Fail: introduce ethanol tainted air into the breath tube during the purge cycle
         4. Interference: connect a water bath simulator with a methanol/water solution to the breath hose
         5. Invalid Sample: provide a breath sample with mouth alcohol
         6. Standard Out of Range: connect an external standard that is a different concentration than what the instrument is set to

11. Perform a Tank Change (F8)
   1. Install a dry gas standard
   2. When performing a Tank Change, the instrument will automatically do an Accuracy Check

12. Subject Breath Test
   1. Initiate a subject breath test (F1)
      1. Introduce a breath sample before the instrument displays "Please Blow"
         1. Record whether or not the test was stopped on the verification form
         2. Inhale during the breath test instead of exhale
         1. Record the resulting error, if any, on the verification form
         3. Provide a breath result above 0.45 g/210L
            1. Using a wet bath simulator containing an ethanol/water solution above a 0.45 g/210L, provide a breath sample through the simulator
            2. Attach printout to verification form
         4. Provide a blank breath sample
            1. Attach printout to verification form
D. Accuracy Checks

1. The accuracy of the Intox-DMT will be checked for a period of time not exceeding 10 days or following the testing of 150 subjects, whichever comes sooner.

2. The instrument shall be checked for accuracy with reference samples which are known as water solutions (wet bath) or dry-gasses of alcohol (ethanol breath standards-EBS).

3. Determination of accuracy shall consist, at minimum, of periodic analysis of a reference sample of known alcohol concentration within accuracy and precision limits of +/- 0.010 g/210L of the true value.

4. Known ethanol/water solutions and/or dry gas reference samples of alcohol may range in concentration from 0.08 to 0.30 g/210L.

5. The results of the determinations of accuracy will be reviewed by a forensic alcohol analyst to determine if the instrument continues to meet the accuracy set forth by Title 17.

6. Accuracy checks are performed on the Intox-DMT in the following ways:

   a. Periodic Determination of Accuracy (PDOA)

      i. A PDOA is an automatic accuracy check done once a week.

         1. PDOA results are downloaded to DMHost and reviewed for accuracy by a forensic alcohol analyst. Refer to BRA.13 for Database Procedures.

      ii. The schedule for PDOA's is set up when the instrument is installed into service in the field.

   b. Accuracy Check

      i. Performed by a forensic alcohol analyst, or qualified Laboratory staff.

         1. From the main menu, choose Accuracy Check (F5)

         2. Scan technician card or complete the required fields:

            1. Technician Information:

               1. Technician name: First initial of first name, full last name

               2. Badge number: employee number

               3. Agency: CCCSO Lab

            2. Control Information

               1. Sim. type: choose dry gas or wet bath

                  1. If using a digital simulator, update the Simulator setting in the Main Menu.

                  2. Connect the digital simulator to the Intox-DMT using the RS232 cable.

               2. Nominal: enter the nominal value of the solution
3. Lot #: lot number and tank number if dry gas or lot number of simulator solution

4. Expiration date: enter expiration date of solution

3. After the required fields are completed, the instrument will begin an accuracy check.

4. At the completion of the accuracy test, enter technician notes. Refer to BRA.16 for common technician notes.

c. Tank Change

i. Performed by a forensic alcohol analyst, or qualified Laboratory staff.

ii. A Tank Change is necessary to ensure the information regarding the external standard is correct for PDOAs and Subject Breath Tests.

iii. From the main menu, choose Tank Change (F8)

iv. Scan technician card or complete the required fields:

1. Technician Information:
   1. Technician name: First initial of first name, full last name
   2. Badge number: employee number
   3. Agency: CCCSO Lab

2. Control Information
   1. Sim. type: choose dry gas or wet bath
   2. Nominal: enter the nominal value of the solution
   3. Lot #: lot number and tank number if dry gas or lot number of simulator solution
   4. Expiration date: enter expiration date of solution

3. After the required fields are completed, the instrument will begin an accuracy check.

4. At the completion of the accuracy check for a Tank Change, technician notes are not required. The forensic alcohol analyst should enter technician notes in the Maintenance Log in the database.

E. Periodic routine maintenance

1. Every 3 months the Intox-DMT should be checked over a linear range. Refer to BRA.10 for directions for the Multi-Level Check.

2. The Intox-DMT will be checked on an annual basis using the Instrument Service Checklist ALC.42.

F. Adjustments

1. The Adjustment sequence of the Intox-DMT establishes a reference in the software that all external tests are measured against.
a. Water and known ethanol solutions are analyzed at three filters
b. Analyzed values are checked against acceptable tolerances for the set levels and stored in the software.
c. Calibration factors are created and applied to each external test.
d. Refer to the Intox-DMT Technician Workbook for Calibration/Adjustment Factors.

2. An Adjustment may need to be performed on the Intox-DMT if:
   a. There is an IR/FC Disagreement
      i. No 0.020 agreement between an IR/FC result.
   b. The results of an accuracy check are outside of the allowable limits
      i. Refer to the Instrument Verification form for specific criteria. ALC.42

3. Performing an Adjustment on the Intox-DMT
   1. Refer to the Intox-DMT Technical Workbook for additional explanation and instruction.
   2. Document the adjustment on an Adjustment Worksheet ALC.43
   3. Supplies needed:
      1. Wet bath simulator containing a traceable 0.100 g/210L ethanol/water solution
         1. After filled with solution, turn the wet bath simulator on and allow to warm up for at least 30 minutes prior to use.
      2. Wet bath simulator containing blank dH2O
         1. After filled with water, turn the wet bath simulator on and allow to warm up for at least 30 minutes prior to use.
      3. Traceable dry gas standard in a concentration of 0.100 g/210L ethanol, uncorrected
         1. Do not use a 0.100% dry gas lot number installed for weekly PDOA's or subject test accuracy tests.
      4. A 12" length of tubing, 1/4" ID, 3/8" OD, 1/16" wall
   4. Print a copy of the last adjustment factors saved in the DMT
      1. From the main menu, choose Reports, then Adj. Factors
   5. From the main menu, choose Setup, then choose Adjustment
      1. Set the Number of Tests to 3
   6. If a digital simulator is being used, update the Simulator
      1. From the Main menu, choose Simulator, then Digital Simulator, choose Guth
   7. From the main menu, choose Adjustment
1. Scan Technician card or complete required fields
2. Follow instrument prompts
   1. When prompted, hook up the water or ethanol simulator, then press "OK"
      1. Pressing "OK" is confirmation to the instrument that the action has been taken and the instrument may proceed with the next step of the process.
   2. When prompted, connect the dry gas tank, press "OK"
      1. Do not disconnect the tank as instructed by the instrument.
3. Once the process is complete, the Intox-DMT will produce a set of Adjustment Factors (Adj Factors)
   1. The Adj Factors will be stored in the software as the reference for all subsequent tests
   2. The Intox-DMT will ignore any incomplete adjustments. Only completed adjustments are stored in the instrument's memory.
8. Verify the Adjustment by analyzing wet bath and dry gas standards
   1. Refer to the Adjustment Worksheet for specific accuracy check instructions. ALC.43
9. Status Messages for the Intox-DMT Dual Sensor
   a. A list of common Status Messages can be found in the Intox-DMT Technical Training Workbook.

END OF DOCUMENT
I. Policy: A multi-level check consists of analyzing two or more reference solutions of known alcohol concentration. This is done using the Accuracy check function and performing a duplicate test at each level.

A. A multi-level check will be performed on each instrument at the following times:
   1. Upon original receipt
   2. Every 3-months
   3. After any service or repair is performed which could potentially affect the calibration

B. Refer to BRA.09 for accuracy test procedures.

C. Levels should be inclusive of the instrument's analytical range.
   1. For example the following levels of dry gas or wet bath solutions can be used:
      a. 0.040% - range of 0.020% - 0.080%
      b. 0.200% - range of 0.150% - 0.250%
      c. 0.300% - range of 0.300% - 0.400%
   2. The same level or lot number of the dry gas standard installed for PDOAs and breath tests should not be used for the multi-level checks.

D. The results for each test shall not differ by more than $\pm 0.010\%$ from the target concentration for reference solutions from 0.080\% to 0.300\%. For reference solutions between 0.020\% to values below 0.08\% the results must be within $\pm 0.005\%$ from the target concentration. For reference solutions greater than 0.300\% the results must be within $\pm 5\%$ from the target concentration. If the instrument does not pass the multi-level check it will not be used for breath testing until the problem is corrected by a qualified laboratory member or repair technician.

E. The results are downloaded to the laboratory computer.

END OF DOCUMENT
I. Policy: Technical procedures to be performed by a forensic alcohol analyst for the installation or removal of an evidentiary breath alcohol instrument. These procedures are to be followed when installing an instrument into service or removing an instrument from service at law enforcement agencies in Contra Costa County. All procedures will be done in accordance to the California Code of Regulations for forensic alcohol testing, as outlined in Title 17.

A. Installation of the Intox-DMT Dual Sensor
   1. Items required for installation:
      a. Intox-DMT Dual Sensor breath alcohol instrument, including power supply adapter
      b. Breath hose
      c. Keyboard
      d. Traceable dry gas standard
         i. Acceptable range of ethanol concentrations: 0.080-0.300 grams/210 L
      e. 6-outlet power strip with surge protection
      f. Mouthpieces
      g. USB ethernet adapter
         i. Example: TRENDnet model TU2-ET100, USB to 10/100 Mbps adapter or equivalent
      h. Ethernet and modem cables
      i. External desktop printer compatible with the instrument's operating system
   2. Optional equipment
      a. 2-D barcode scanner with ethernet cable and power cord
         i. Example: E-SEEK Model 260 or equivalent
      b. Wet bath simulator
         i. Example: Guth 34C, 2100, or 12V500
ii. Traceable simulator solution
iii. serial data cable for simulator temperature sensor

3. Install instrument at police agency, making sure the following are properly connected:
   a. Power cord from Intox-DMT to power strip
   b. Breath hose into port and electrical into appropriate receptacle
      i. The breath hose must be connected to warm up to temperature
   c. Keyboard to the Intox-DMT
   d. Card reader to the Intox-DMT and power strip
   e. Printer to Intox-DMT and power strip
   f. Dry gas canister to regulator
   g. USB ethernet adapter
   h. Ethernet and modem cables from Intox-DMT to connection port(s)

4. Turn on instrument and allow to warm up.
   a. The Intox-DMT may need to acclimate to the room conditions.

5. While the instrument warms up, check the settings in the following sections of the Setup Menu (see ALC.40 or BRA.09):
   a. DMT
   b. Units
   c. Simulator
   d. Subject
   e. Accuracy Check
   f. Tank Change
   g. PDOA
      i. Set the PDOA at the end of the instrument installation. If required, the instrument will automatically perform a PDOA.
   h. Diagnostic
      i. Printer
      j. Internet
         i. The instrument needs to be turned off and on to reset the Internet connections.
   k. Hardware
   l. Software
   m. Control Panel
6. After the settings have been checked and the instrument has finished its warm up, perform a filter test.
   a. Allow the instrument to perform at least 15 cycles.
   b. Record the number of cycles and number of errors on ALC.40.
      i. Remedial action may be need to be taken if there are any errors during the Filter Test.

7. Perform a diagnostic test and retain the printout with ALC.40.

8. Perform a Tank Change.
   a. Record the target concentration on ALC.40 and retain the results printout with the form.

9. Check the modem and ethernet connections.
   a. The lab's host computer will need to call the instrument to check the modem is set up.
   b. While at the instrument, check to see if the internet connection icon is present at the bottom right of the screen, and if the blue arrow appeared to indicate communication with the SFTP server.
   c. Upon returning to the lab, ensure the data downloaded from the instrument.

10. Enter service notes in the instrument maintenance log.

B. Removal of the Intox-DMT Dual Sensor from service at an agency, see ALC.41.

   1. Perform an accuracy check, if possible.
      a. Retain printout with ALC.41

   2. Change the location of the instrument (in the Setup Menu) to CCCSO Lab.

   3. Change the PDOAs to every 52 weeks.

   4. Turn off the instrument, unplug from outlet, and return instrument to the lab.

   5. Enter service notes in the instrument maintenance log.

END OF DOCUMENT
I. Policy: Breath testing instruments used at DUI Checkpoints must be installed, checked for accuracy, and removed by Laboratory qualified personnel. The procedures for instrument installation and removal for a DUI Checkpoint must be done in accordance to Title 17.

A. Intox-DMT Dual Sensor Equipment/Materials
   1. Intox-DMT Dual Sensor breath alcohol instrument, including power supply adapter
   2. Breath hose
   3. Keyboard
   4. Traceable dry gas standard
      a. Acceptable range of ethanol concentrations: 0.080-0.300 grams/210 L
   5. 6-outlet power strip
   6. Mouthpieces
   7. Printer
      a. Power supply cord
      b. cable to connect to Intox-DMT
      c. paper
   8. Precautionary checklist
   9. Optional equipment
      a. 2-D barcode scanner with ethernet cable and power cord
         i. example: E-SEEK Model 260 or equivalent
      b. Wet bath simulator
         i. example: Guth 34C or 2100
         ii. Traceable simulator solution

B. Starting DUI Checkpoint (Set-up Procedure)
   1. Install instrument, connecting all external components, and allow instrument to warm up.
2. While the instrument is warming up, update the instrument:

3. Change location
   a. Go to the main menu, choose Setup (F3)
      i. Choose DMT
      ii. Choose Location and update to DUI CK PT-Host Agency
         1. example: DUI CK PT-Concord PD
   b. Choose Accuracy Check
      i. set Number of Tests to 2
   c. Choose Tank Change
      i. set Number of Tests to 2

4. After the instrument has warmed-up and is ready for testing perform a Tank Change
   a. Go to the main menu and choose Tank Change (F8)
      i. When performing a tank change, the instrument will save the information for the dry gas standard that will be used for any breath test administered during the DUI Checkpoint.
   b. Enter the required information in the requested fields.
   c. The Lot number entered for the dry gas standard is the lot number and tank number of the tank being used.
      i. For example: Lot # AG707401, tank #021 is entered as AG707401021
   d. The Tank Change will serve as the installation accuracy test.
   e. After the successful completion of the Tank Change the instrument is ready for use.

C. Ending DUI Checkpoint (Break-down Procedure)
   1. Perform an Accuracy Check (F5)
      a. Go to the main menu, choose Accuracy Check
         i. Enter the required information in the requested fields.
         ii. Enter the dry gas tank lot number as above.
      b. Upon successful completion of the Accuracy Check, enter technician notes as:
         i. Pass-removing instrument from DUI Checkpoint

2. Change Location back to CCCSO LAB
3. Disconnect external components and carefully pack instrument in carrying case.
4. At earliest convenience, retrieve the data to the Crime Lab breath alcohol database.
   1. Add a note in the Maintenance Log for the instrument used for the DUI Checkpoint
1. Entry for the installation
   1. example: Instrument 500510 installed at DUI Checkpoint per procedures. Instrument functioning properly.

2. Entry for the removal
   1. example: Instrument 500510 removed from service at DUI Checkpoint per procedures. Instrument functioning properly.

END OF DOCUMENT
I. Policy: The following is general information about Breath Test Operator Training. Only qualified Operators shall perform breath tests on subjects. Such qualified Operators are Forensic Alcohol Analysts (FAA) or persons who have received and passed the Breath Test Operators Training course as described below. Breath test operator training applies to the Intoximeters, Inc. Intox DMT Dual Sensor breath alcohol testing device.

A. General Information

1. All breath test operators, that are not FAA shall have successfully completed the approved training course designed for the instrument model used. The course will consist of at least 4 hours of classroom lecture and practical experience operating the breath testing instrument.

2. The Operator Training Course shall be under the direct supervision and instruction from a Forensic Alcohol Analyst. A Forensic Alcohol Analyst is a Laboratory staff member who meets the qualifications of Title 17 and has successfully completed the breath instrument training and have at least 6 months of practical experience with the instrument. Assistance in training may be rendered to the instructor by a currently qualified operator of the instrument model used.

3. A person who successfully completes the Operator Training Course shall be issued an Operator Card, which serves as a training certificate. The operator card is labeled with the instrument which the operator is certified to use, operator's name, ID/badge number, agency, and the instructor's name. The Operator Cards also contain a bar code that can be used with the card reader installed with the instrument. Such certification shall be valid indefinitely for that model of breath instrument or until the operator demonstrates to the laboratory an inability or refusal to follow proper breath test procedures. Under such conditions, certification shall be revoked and the Operator and the Operator's agency shall be notified.

4. Operator training records shall be maintained by the Laboratory for at least three years.
   a. See the CLER.DAT.11 for instructions on using creating Operator cards using the Operator Database. Operator cards will serve as a certificate of operator class completion.

B. Training: The instructor shall cover the following outline in the procedures for breath alcohol analysis. The instructor will cover, at minimum, theory of operation, detailed procedure of operation, practical experience, Precautionary Checklist, and a written examination. All students will receive a copy of the Operator Course Handout (see below).

1. Introduction
   a. Explain nature of course.
   b. Explain Title 17 and its requirements as they apply to breath testing and breath test operators.

2. Alcohol as a chemical
3. Alcohol and the Human Body
   a. Explain the absorption, elimination, and physiological effects of alcohol.
   b. Emphasize route of elimination, particularly physiology of breath elimination.

4. Chemical tests for alcohol
   a. Discuss Title 17 and its requirements for blood and urine as samples for alcohol analysis.
   b. Discuss blood, breath, and urine as samples, point out attributes of each.
   c. Discuss which samples are best for various types of drug detection.
   d. Discuss Trombetta sample.

5. Breath test devices
   a. Briefly describe the Federal Department of Transportation approval process for breath test instruments.
   b. Discuss the common elements of all breath test instruments such as one specific function, alveolar breath, California Department of Public Health approval, and use by qualified operators with an approved Precautionary Checklist.

6. Role of the operator
   a. Administer breath tests.
   b. Follow instrument procedures, as instructed by the laboratory including the Precautionary Checklist.
   c. Adhere to Title 17 requirements.
   d. Operators who are not Forensic Alcohol Analysts, as deemed by the Title 17 and the Laboratory, are not responsible for maintenance, periodic determination of accuracy, or any ancillary activities for the Intox DMT Dual Sensor breath testing instrument.
   e. It is the responsibility of the agency to monitor and replace the paper and ink cartridge in the external printer installed with the Intox-DMT Dual Sensor. Replacing printer paper and ink cartridges is not considered a Laboratory maintenance function.
   f. Notify the Laboratory if there are any issues with the instrument.
      i. Notify supervisor to contact the Crime Lab during regular business hours.
      ii. Call the Forensic Alcohol Unit, leave a message if necessary.
      iii. Use a breath instrument at a different agency or at the Martinez Detention Facility
      iv. Draw blood instead of administering a breath test.

7. Role of the laboratory
   a. Train operators.
   b. Maintain breath test instruments.
      i. Perform or check periodic determination of accuracy on the breath test instruments.
         1. Accuracy checks are done by an FAA using a dry gas standard or a wet bath simulator solution.
      ii. Perform maintenance tests.
      iii. Perform tank changes.
      iv. Troubleshoot instrument issues installed for service at each agency.
c. Maintain forensic alcohol records. The following records are downloaded to a host computer in the Crime Laboratory:
   i. Accuracy check
   ii. Tank change
   iii. Periodic Determination of Accuracy (PDOA)
   iv. Maintenance tests
   v. All breath records
d. Supply expert testimony in court regarding theory and operation of instrument.
e. Interpret alcohol levels and provide opinion regarding impairment.
f. Adhere to Title 17 requirements.

8. Theory of operation
   a. Explain the value and purpose of forensic alcohol testing.
   b. Explain the theory of breath alcohol analysis.
   c. Discussion of the required 15 minute wait period.
   d. Explain the methods of breath alcohol testing.

9. Instrument Description
   a. Use an instrument, its accessories and visual aids to point out and discuss the components.
   b. Describe function and use of the digital display, tubes, buttons, keyboard, magnetic strip reader, etc.

10. Detailed procedure of operation and precautionary check list
   a. Read and explain the precautionary check list to the students. This checklist will be maintained at each instrument site.
   b. Give a detailed description of each step of the test.
   c. Explain the effects of mouth alcohol on a breath test and why the 15 minute observation time is necessary. Emphasize that another 15 minute observation time must be performed if mouth alcohol is detected.
   d. Re-emphasize the need and procedure for obtaining alveolar (deep lung) breath.
   e. Discuss the Advisory Concerning Sanitary Practices During Administration of Breath Alcohol Tests.
   f. Discuss the expression of analytical results.
   g. Emphasize the necessity to obtain two separate breath samples which result in determinations of breath alcohol concentrations which do not differ from each other by more than 0.02 grams per 210 liters. Explain steps to be taken if a third breath sample is needed to obtain 0.02 agreement.
   h. Explain the test card and the precautionary checklist and emphasize that it is to be retained in the officers' case file.

11. Written exam
   a. The individual must pass with a score of 80% correct answers.
   b. Allow the students 25 minutes to complete the exam.
   c. See written exam below.

12. Practical experience and examination
   a. Each instrument screen prompt shall be discussed and reviewed the instructor.
   b. The operation of the breath instrument shall be demonstrated by the instructor.
c. The instructor shall observe the trainee(s) perform a successful test on the instrument.
d. The practical examination is successfully complete when the student demonstrates to the instructor
correct hands-on operation of the Alcotest 7110 MK III C or the Intox-DMT
e. Dual Sensor using the precautionary check list.
f. The instrument test record and the precautionary check list will be submitted by each student and
retained in the laboratory records.

II. INTOXIMETERS – INTOX-DMT DUAL SENSOR OPERATOR TRAINING COURSE HANDOUT

A. Introduction

1. Nature of Course: The purpose of this course is to train operators on how to properly conduct a breath test
on the Intoximeters, Inc. Intox DMT Dual Sensor breath alcohol instrument. The content of this course
will include theory of operation, detailed procedure of operation, and practical experience on the
instrument. The course will also cover the physical properties of alcohol and its physiological effects on
the body. This course handout is to be used in conjunction with the Operator Training course instructed
by a qualified Forensic Alcohol Analyst employed by the Contra Costa County Criminalistics Laboratory.

2. Regulatory Aspects of Forensic Alcohol Analysis

a. In California, the agency authorized by law to regulate forensic alcohol testing programs is the
California State Department of Public Health. This department has set forth its requirements in
Title 17 of the California Code of Regulations.
b. Forensic alcohol analysis means the use of specialized equipment, instruments, and methods to
measure the concentration of alcohol in samples of blood, urine, or tissue of persons involved in
traffic accidents or traffic violations.
c. Forensic alcohol analysis shall be performed by a laboratory that meets the requirements of Title 17
set by the California Department of Public Health as a Forensic Alcohol Laboratory.
d. All aspects of forensic alcohol analysis, including the content of this class and handout, are subject
to review by the California Department of Public Health.

B. Alcohol as a Chemical

1. “Alcohol”, as written in Title 17 and this laboratory's methods, refers specifically to ethyl alcohol
(ethanol). Ethanol is the alcohol found in alcoholic beverages such as beer, wine, vodka, and rum.
Alcoholic beverages also contain chemicals known as congeners which give the beverage its flavor, color,
and odor. The odor detected, in a drink or on the subject's breath, is usually due to the congeners not the
ethanol. A few types of alcohol or similar compounds are:

a. Ethyl Alcohol: Grain alcohol. Ethanol is completely soluble in water. Alcoholic beverages will
often list the alcohol concentration as Proof. The proof is two times the percentage of alcohol by
volume. A bottle of vodka labeled “100 proof” will be 50% alcohol by volume.
   i. TOXICITY: 13 to 16 oz.
b. Methyl Alcohol: Wood alcohol. Methanol is used as a solvent or fuel and very small amounts may
be found in wines and liquor. Methanol metabolizes (is broken down in the body) into formic acid,
which damages the optic nerve. Consumption may lead to blindness.
   i. TOXICITY: 1 to 3 oz. (five times as toxic as ethanol).
c. Isopropyl Alcohol: Rubbing alcohol. Isopropanol is used as a solvent, fuel, antiseptic, antifreeze,
and is also found in colognes. Isopropanol metabolizes to acetone.
   i. TOXICITY: 8 oz. (twice as toxic as ethanol).
d. Acetone: Acetone is found in fingernail polish remover and may be present in a person's system if
they are diabetic, on a fasting diet, or had consumed Isopropyl alcohol. It is produced naturally in
the body, at very low levels, from the metabolism of fats.

C. Alcohol and The Human Body

1. Absorption
a. When ethyl alcohol is ingested, (when a person drinks an alcoholic beverage), it will travel first to the stomach where approximately 20-25% is absorbed into the blood stream. The remaining alcohol will then be emptied into the small intestine where it will be absorbed into the blood stream. The absorption of alcohol into the blood stream is by diffusion across the walls of the stomach and small intestine. There are many factors that can affect the rate of absorption including the type of drink consumed, the concentration of alcohol in the drink, how fast it is consumed, and the contents of the stomach while drinking (empty or full).

2. Distribution
a. The alcohol, after it has been absorbed into the blood stream, will be distributed throughout the body via the blood supply. The distribution of the alcohol is based on the water content of the body tissues; those with a high water content such as brain and muscle tissue will receive more alcohol than the bone or fatty tissue, which have a very low water content.

3. Elimination
a. Approximately 90% of the alcohol consumed is eliminated from the body by oxidative metabolism occurring largely in the liver. The remaining alcohol is excreted through the breath, urine, and skin by perspiration. The passive, predictable elimination of small amounts of alcohol through the breath and urine makes it possible to use urine or breath samples in determining the blood alcohol concentration.

b. Urine is produced as water and metabolic wastes are removed from the blood in the kidneys. The small amount of water removed will carry with it the same concentration of alcohol as the water in blood. This is because alcohol and water are infinitely soluble. It has been well established that the concentration of alcohol found in the urine will be higher than the concentration of alcohol in the blood by a ratio that has been determined to be 1.3 to 1.

c. Because urine is constantly being produced by the kidneys, it is necessary to have a subject void his or her bladder before giving a urine sample for analysis. The void eliminates urine that would reflect the average blood alcohol level for the time interval since the previous urination (which could have been several hours prior). The sample collected at least 20 minutes after the void reflects the blood alcohol over those 20 minutes.

d. As blood circulates through the lung tissue an exchange of gases occurs. Carbon dioxide is exchanged for oxygen. At body temperature (37°C) a small amount of alcohol will become a gas. This amount has been determined to be one part of alcohol as gas for every 2100 parts of alcohol that stays in the blood as a liquid. This equilibrium between blood and breath is established almost instantly in millions of tiny “pockets” in the lung called alveoli (deep lung tissue). The breath in the channels leading to the alveoli (throat, trachea, bronchial tubes, etc.) contains various mixtures of room air and deeper lung air. Consequently, this “top lung” air does not reflect the true blood-breath equilibrium. It is a varying amount less in alcohol concentration than in the deep lung air. For this reason the first part of an exhalation has the lowest concentration of alcohol in the breath. The highest concentration is reached from the last part of exhalation and contains the breath that reflects the true blood alcohol concentration.

e. The total rate of elimination of alcohol (metabolism, breath, excretion) varies slightly from person to person. The average rate is about 0.02% of blood alcohol concentration per hour, or about 1 oz. of 100 Proof alcohol for a 180 lb. man.

4. Physiological Effects
a. Alcohol is a drug that depresses the central nervous system. It first affects inhibition and judgment and then impairs motor performance of all kinds, including vision, hearing, and muscular coordination. Pharmacologists agree that the effects of alcohol on the brain are always a deterioration of function and never an improvement.

b. The following information is from a Council Report by the Council on Scientific Affairs (JAMA 1986;255:522-527). "There is scientific consensus that alcohol causes deterioration of driving skills beginning at 0.05% BAC or even lower, and progressively serious impairment at higher BACs." There is accumulating evidence that demonstrates a direct relationship between BAC in drivers and the risk of a motor vehicle crash. Alcohol impairs driving skills by its depressant effect on the central nervous system. Alcohol slows and decreases the efficiency of both information acquisition and information processing, making divided attention tasks such as steering and braking more difficult to perform without error.
c. The American Medical Association supports a policy recommending:
    i. Public education urging drivers not to drink
    ii. Adoption by all states of a 0.04% BAC as per se illegal for driving (per policy H-30.986, modified in 1997)
    iii. 21 years as the legal drinking age in all states
    iv. adoption by all states of administrative driver's license suspension in DUI cases

5. Perspective
   a. At this point it is important to emphasize that a chemical test for intoxication can substantiate the arresting officer's observations as to the individual's impairment. However, it should not be considered the only available criterion as to whether or not a person is under the influence. The totality of a well documented investigation, a properly administered breath test along with field sobriety tests and observations are extremely valuable in determining an individual's degree of alcohol impairment.

D. Chemical Tests for Alcohol
   1. There are three types of samples, blood, breath, and urine, which may be used for alcohol analysis. The standards for withdrawal, testing, and preservation are established by Title 17.
   2. Blood
      a. Blood samples are collected by venipuncture only by persons authorized by Section 23158 of the California Vehicle Code (i.e., only licensed physician and surgeon, registered nurse, licensed vocational nurse, duly licensed clinical laboratory scientist or clinical laboratory bioanalyst, a person who has been issued a “certified phlebotomy technician” certificate pursuant to Section 1246 of the Business and Professions Code, unlicensed laboratory personnel regulated pursuant to Sections 1242, 1242.5, and 1246 of the Business and Professions Code or certified paramedic acting at the request of a peace officer may withdraw blood for the purpose of determining the alcohol content therein.
      b. The vials used to collect the blood sample must contain a preservative and anticoagulant.
      c. The officer must witness the blood withdrawal, initial the blood labels, and sign the chain of custody on the envelope. This is done to establish the chain of custody.
      d. The advantages of taking a blood sample include:
         i. Sample available for reanalysis
         ii. Sample may be tested for other drugs
      e. The disadvantages are:
         i. Requires a trained third party
         ii. Invasive
         iii. Test results are not immediately available
   3. Breath
      a. Only persons who have passed the Operator Training Course may conduct a breath test on a subject.
      b. The subject must be observed continuously for at least 15 minutes prior to the breath test.
      c. The breath test is conducted by following the Precautionary Checklist.
      d. An acceptable test must have 0.02 agreement between two duplicate breath samples.
      e. The advantages of taking a breath sample include:
         i. Test results are immediate
         ii. Non-invasive
      f. The disadvantages are:
i. Tests only for alcohol
ii. Sample is not retained for reanalysis

4. Urine
   a. The sample bottles must contain a preservative.
   b. The urine sample for alcohol analysis must be taken at least 20 minutes after the subject voids their bladder.
   c. The advantages of taking a urine sample include:
      i. Sample available for reanalysis
      ii. Sample may be tested for other drugs
      iii. Non-invasive
   d. The disadvantages are:
      i. Test results are not immediate
      ii. Waiting period between void and sample
      iii. Officer must witness the sampling

E. Breath Test Devices
   1. All breath testing instruments used must be on the Federal Department of Transportation's list of approved instruments. The following are elements common to all breath testing instruments used in California:
      a. One specific function - to measure the amount of alcohol present in a subject's breath sample
      b. Designed to measure the alveolar (deep lung) breath
      c. Approved by the California Department of Public Health
      d. Used by qualified operators using an approved Precautionary Checklist

F. Role of the Operator
   1. The operator is required to do the following:
      a. Administer the breath test
      b. Follow the Precautionary Checklist
      c. Follow instrument procedures as instructed by the laboratory
      d. Adhere to Title 17
      e. Provide testimony as to how the breath test was administered
      f. Follow the "California Department of Public Health" Advisory Concerning Sanitary Practices During Administration of Breath Alcohol Tests"

G. Role of the Laboratory
   1. The laboratory is required to do the following:
      a. Train operators
      b. Maintain the breath test instruments
      c. Perform or check periodic determinations of accuracy on the breath test instruments
      d. Maintain forensic alcohol records
      e. Supply expert testimony in court regarding the theory and operation of the instrument
      f. Interpret alcohol levels
      g. Adhere to Title 17 requirements.
H. Theory of Operation

1. The Intoximeters, Inc. Intox-DMT Dual Sensor contains two independent measuring systems, infrared absorption (IR) and an electrochemical fuel cell sensor (FC), to determine the amount of alcohol present in a subject's breath sample. By combining two distinct analytical systems to analyze a subject's breath sample, the Intox-DMT Dual Sensor is able to provide two precise, accurate, and independent test results. The raw results are expressed to the third decimal place and the reported result is averaged and truncated to the second decimal place. The reported result is expressed as g/210L of breath alcohol. Due to the fact that these systems are based on different technologies, it is therefore not unusual to observe slightly different results.

2. Infrared Absorption
   a. General:
      i. INFRARED ABSORPTION is a property of all organic molecules. This property obeys the well-known Lambert-Beer Law of Absorption where:
         
         \[ I = I_0 e^{-abc} \]
         
         i is the energy emerging from the gas absorption cell
         ii. I0 is the incident energy entering the gas absorption cell
         iii. e is the natural logarithm base
         iv. a is the absorption coefficient for ethyl alcohol at the wavelength in question
         v. b is the light path length in the gas absorption cell
         vi. c is the concentration of alcohol in the breath
         ix. The concentration of alcohol, c, is readily determinable since a and b are constants and I/I0 is measured by the instrument.
   b. Specific to the Intoximeters, Inc. Intox-DMT Dual Sensor:
      i. The Intox-DMT Dual Sensor detects alcohol at 3.44 µm in the IR spectrum.
      ii. The infrared absorption sample chamber, where the breath sample is analyzed, is the central part of the measuring system. The breath sample is transferred into the system via the breath hose. The sample chamber is heated to 46-50° C to avoid condensation and to guarantee defined conditions for the analysis. The sample chamber is a multi-reflection cell which provides a long absorption path for high precision. The sample chamber also has a small volume, which makes it possible to trace the concentration-time profile very carefully because fast changes are noticed.
      iii. The Intoximeters Intox-DMT has a kanthal infrared source lamp at one end of the sample chamber. At the other end of the sample chamber is a thermo-electrically cooled lead selenide detector. The detector is cooled to improve the signal sensitivity and precision.

3. Electrochemical Fuel Cell Sensor
   a. General:
      i. The ELECTROCHEMICAL FUEL CELL SENSOR (FUEL CELL) measures the current between a working and reference electrode with contact leads that are separated by a porous membrane filled with an electrolyte. Ethanol trapped on the working electrode is converted according to:
         
         \[ \text{Working electrode: } C_2H_5OH + 3H_2O \rightarrow 2CO_2 + 12H^+ + 12e^- \]
         
         iii. Reference electrode: \( 3O_2 + 12H^+ + 12e^- \rightarrow 6H_2O \)
      iv. The change in the electronic configuration causes a current between the electrodes.
   b. Specific to the Intoximeters Intox-DMT:
      i. When the FC detector is ready to analyze a sample, it opens to allow a fixed amount of the sample from the IR cuvette to enter the FC sensor. In its simplest form, the fuel cell consists of a porous acidic membrane (electrolyte) which is laminated by two platinum black plates.
This assembly is packed into a sealed case which has one small hole (sample inlet) leading to the sample chamber.

ii. Only one platinum plate will be exposed to the breath sample. A chemical reaction is triggered. The chemical reaction produces an electrical current between the two platinum plates, the voltage of which is measured. This becomes the usable indicator of the amount of alcohol consumed by the fuel cell, and is directly proportional to the amount of alcohol in the breath sample.

4. Detection of Interfering Substances
   a. The Intox – DMT fuel cell is designed for specificity to alcohol. The main response of the fuel cell is to ethanol. However, there is some mild sensitivity to other low molecular weight alcohols, such as isopropyl alcohol and methanol. There is virtually no sensitivity to butanol, which has 4 carbons.
   b. The fuel cell has no reaction at all to acetone, and only a very mild reaction with acetaldehyde. The fuel cell memorizes the response to ethanol in the form of a curvature analysis profile. The presence of another substance can be detected by comparing the time constant of the curve to the saved ethanol curve. If the subject’s breath sample reveals different curvature characteristics, the message INTERFERENCE will be generated. The test will be invalidated.
   c. The Intox – DMT infrared absorbance is measured at 3.445 µm (filter 1), at 3.373 µm (filter 2), and at 3.501 µm (filter 3). Although multiple substances also have absorption at 3.445 µm, the signal ratio between the three filters is unique to ethanol. If a signal is detected, but the expected ratio between the filters is exceeded, the instrument will display and print out INTERFERENCE.
   d. For example, the absorbance profile in red is ethanol. The filter with the highest absorbance is filter 2, the second highest absorbance is filter 1, and the least absorbance is filter 3. The absorbance profile in green is an interfering substance. The filter with the greatest absorbance is filter 1, followed by filter 2, and finally by filter 3. The ratios between the filters are exceeded, and the instrument will display and print out INTERFERENCE.

5. Radio Interference (RFI)
   a. There is a radio frequency detection antenna on the breath hose of the Intox - DMT that looks for possible interfering radio frequencies. If this circuit was activated, RFI DETECTED will be printed on the subject test print-out. The RF circuit is not designed to detect all RF signals that may be generated, but only those that are of sufficient strength.

6. Flow Sensor
   a. There is a flow sensor that measures the breath flow (how hard the subject is blowing into the instrument) during a subject's test. This detector reacts quickly and interruptions in the flow of the breath sample can be easily detected.

7. Breath Hose
   a. The breath sample is transferred through a breath hose into the cuvette. The flexible breath hose is heated to 48 degrees C (+2 degrees C or -8 degrees C) to avoid condensation of the breath sample.

8. Mouth Alcohol Detection
a. Mouth alcohol is characterized by a sharp increase of alcohol concentration in the beginning of the subject's breath sample followed by a decrease of alcohol concentration until the end of the sample. A negative slope is detected if the change in consecutively compared averages are greater than 0.001 in the negative direction.

9. Profile Analysis

a. Various criteria must be met in order for the instrument to accept a breath sample and to ensure that the breath sample analyzed represents an alveolar (deep lung) air sample. The following conditions must be satisfied before the profile analysis is activated:

i. MINIMUM FLOW RATE: 3.0 L/min.

ii. MINIMUM BREATH VOLUME (at minimum flow rate): 1.5 L

iii. PLATEAU OF BREATH CURVE: The increase from the second to last 2 point average to the last (at the time the flow rate drops below 3.0 L/min) must be less than or equal to 0.001 grams / 210 liters and not a negative slope.

iv. A negative slope is detected if the change in consecutively compared averages are greater than 0.001 in the negative direction.

I. Detailed procedure for operation for the Intox-DMT Dual Sensor

1. To perform a proper breath test on the Intoximeters Intox-DMT, an operator must:

a. FOLLOW THE PRECAUTIONARY CHECKLIST (See copy of the Precautionary Checklist)

2. Preparing for Breath Test

a. Subject: The subject must be under continuous observation for a minimum of 15 minutes prior to performing a breath test. Per Title 17, during this period the subject must not have ingested alcoholic beverages or other fluids, regurgitated, vomited, eaten, or smoked. The subject should also not use a mouth spray, mouth drops, place anything in their mouth, or belch.

i. The purpose of the waiting period is to prevent mouth alcohol, which is any residual alcohol remaining in the mouth due to drinking an alcoholic beverage, vomiting, or regurgitating, from interfering with the test. It is NOT recommended that this observation be performed in the patrol car. The observation should be performed while in the same room as the subject to ensure that the subject has not ingested alcoholic beverages or other fluids, regurgitated, vomited, eaten, or smoked.

b. Intoximeters, Inc. Intox-DMT Dual Sensor: The Intox-DMT is equipped with a touch screen. A dedicated stylus should only be used and located near the instrument. If the screen on the Intox-DMT is blank or the screen saver is on, tap the screen. The home screen will appear. If the date and time are not correct on the instrument, make a note of it in your report and notify the Crime Lab.

3. Performing a Breath Test

a. To start the test, tap the green START TEST circle on the home screen.

b. The instrument will display: Has the 15-minute observation period been completed? Tap the Yes or No button on the screen.

c. The instrument will display: Scan Driver’s License? Tap the Yes or No button on the screen.

d. The instrument will now display the Test Information screen. Information is entered into each box/field using the keyboard. Switch between boxes/fields either by tapping on the one you want or by using the Tab button on the keyboard to navigate through each of the boxes/fields.

e. Under Observation Information, enter the observation start time and end time in the format HH:MM.

f. Under Subject Information, enter the subject’s name (first, middle initial, last), the subject’s license, and choose the gender from the pull-down menu. Enter the date of birth in the format MM/DD/YYYY. The age of the subject will auto-populate.

g. Under Operator Information, enter the operator’s name (first, middle initial, last), badge number, and agency. The operator will be alerted if “enter” is hit prior to entering the required information.
Tap on the empty field and enter the required information. Alternatively, press Tab to navigate through the fields. To continue, press the NEXT button.

h. The instrument will now display the Arrest Information screen. Enter the arrest city and choose whether this location is a City (C) or an Unincorporated (U) location via the pull-down menu. Enter the street address, the nearest cross-street, and the case or citation number. Entering remarks is an optional field.

i. When completed, tap one of the following options:
   i. Previous – To return to the previous screen
   ii. Cancel – To stop the test
   iii. OK – To start the subject breath test

1. If the OK button was tapped, the instrument will display the test screen. A series of self-tests are automatically performed by the instrument. This includes a purge, ambient zeroing, diagnostic check, and blank test.

j. The instrument will display: Did the subject refuse? Tap the Yes or No button on the screen. Yes will end the test. No will continue the breath test.

k. Insert a new mouthpiece into the breath hose. Follow the Advisory Concerning Sanitary Practice During Administration of Breath Alcohol Tests section.

l. The instrument will display “Please Blow” and will give a series of beeps when the subject is to deliver the breath sample. The Operator may hold the breath hose or allow the subject to hold the breath hose while the breath sample is being given. Instruct the subject to inhale calmly and to blow continuously and evenly into the mouthpiece until they are out of breath. The beeps will change to a solid tone when the breath sample is being delivered. A green bar on the bottom right of the screen elongates as the breath sample is being delivered. The green bar should reach at least the halfway mark during the breath test. Remove the mouthpiece at the completion of the breath sample.

m. During the 2 minute waiting period between subject breath test, the instrument will perform the following: purge, ambient zeroing, blank, external standard, purge, ambient zeroing, and a blank.

n. The instrument will again display: Did the subject refuse? Tap the Yes or No button on the screen.
   i. Yes will end the test.
   ii. No will continue the breath test.

o. Insert the mouthpiece into the breath hose. Follow the Advisory Concerning Sanitary Practice During Administration of Breath Alcohol Tests section.

p. The instrument will again display “Please Blow” and will give a series of beeps when the subject is to deliver the breath sample. The Operator may hold the breath hose or allow the subject to hold the breath hose while the breath sample is being given. Instruct the subject to inhale calmly then blow continuously and evenly into the mouthpiece until they are out of breath. The beeps will change to a solid tone when the breath sample is being delivered. A green bar on the bottom right of the screen elongates as the breath sample is being delivered. The green bar should reach at least the halfway mark during the breath test. Remove the mouthpiece at the completion of the breath sample.

q. The instrument will automatically perform more self-tests: a purge, ambient zeroing, blank, external standard, purge, ambient zeroing, and a blank.

4. This is the end of the subject breath test. A report will be generated.

a. Sign the bottom of the report. Retain the signed Breath Alcohol Analysis Report with the officer’s case file. If during the breath test the subject refused, or the test was stopped due to a status code, the printout(which includes the precautionary checklist)should be included with the officer's case file.

b. If an additional copy of the breath alcohol analysis report is desired, tap the COPY button on the home screen. Tap LAST TICKET and then tap PRINT.

5. Printout of Final Result – Breath Alcohol Analysis Report (see below).
If a printing problem occurs, tap the COPY button on the home screen. Tap LAST TICKET and then tap PRINT.

J. Status Messages - Causes and Remedies

1. The following are some of the common status messages which may occur during a breath test. The status message will be shown on the instrument’s digital display.

   a. PUMP ERROR – The message “PUMP ERROR” will be generated if at any time during the purge cycle the flow rate drops below 3 liters per minute. Repeat breath test. If the error persists, contact the Crime Laboratory.

   b. FILTER (1, 2, or 3) WON’T ZERO – The message “FILTER (1, 2, or 3) WON’T ZERO” will be generated identifying which filter (3.44µm, 3.37µm, or 3.50µm) won’t zero. If encountered, contact the Crime Laboratory.
c. **AMBIENT FAIL** – The INTOX-DMT checks for changes in alcohol concentration in the ambient air. The detector quantifies any signal produced both at the beginning and at the end of the purge cycle. If the difference between these two readings is ≥ 0.12 Vdc, the message “AMBIENT FAIL” will be generated. A possible cause of an ambient fail is the presence of a subject with a strong odor of alcohol or perfume in proximity to the instrument.

d. **BLANK ERROR** – The INTOX-DMT checks for baseline levels of alcohol concentration in the ambient air. Blank tests are performed before and after each breath sample when the 3.44µm filter is in the optical path. If a value ≥ 0.004g / 210L is measured, the message “BLANK ERROR” will be generated. A possible cause of a blank error fail is a baseline level of alcohol in the air caused by hand-sanitizers, Lysol, air fresheners, etc. in proximity to the instrument. Remove any of these items from the breath testing room and retry the test.

e. **STANDARD OUT OF RANGE** – The external standard measurement must fall within the specified range of the target value. If the measurement falls outside of this range, the message “STANDARD OUT OF RANGE” will be generated. The instrument will disable itself. If encountered, contact the Crime Laboratory.

f. **INTERNAL STANDARD ERROR** – During the PDOA and the Diagnostic Tests, the internal quartz standard is measured. This internal standard measurement must fall within ± 4% of the stored Xq value established when the instrument was calibrated. If it falls outside of this range, the message “INTERNAL STANDARD ERROR” will be generated. If encountered, contact the Crime Laboratory.

g. **INVALID SAMPLE** – While a breath sample is being delivered, the instrument is continually measuring the concentration of alcohol. A decrease in the concentration of alcohol over time would result in a negative slope in the breath alcohol curve. If specific negative slope criteria are met, the message “INVALID SAMPLE” is generated. The current subject breath test will end, a print-out will be generated with the message “INVALID SAMPLE” and the instrument will return to the home screen. The most likely reason the “INVALID SAMPLE” message was triggered was because of mouth alcohol in the subject’s breath. Re-start the 15 minute observation period, then retry the test.

h. **DETECTOR OVERFLOW** – When the detector voltage exceeds the maximum measurement of ± 2 Vdc, the message “DETECTOR OVERFLOW” will be generated. This corresponds to approximately a 0.83% BrAC. A possible cause of this is excessive mouth alcohol. Re-start the 15 minute observation period, and retry the test.

i. **SAMPLE CHAMBER TEMPERATURE CHECK** – The Intox – DMT will only operate if the sample chamber is in the range of 46°C to 50°C. Anything outside of this range will trigger the message “SAMPLE CHAMBER TEMPERATURE CHECK” to be generated. Typically, it takes 20 minutes from the time that the instrument is first powered on for the sample chamber to reach 46°C. Allow sufficient time for the instrument to warm up. If the correct temperature still is not reached, contact the Crime Laboratory.

j. **BREATH TUBE TEMPERATURE CHECK** – The Intox – DMT will only allow a breath sample to be administered if the breath hose is heated to 48.1°C (+2°C or -8°C.) If the breath hose temperature is outside of this range, the message “BREATH TUBE TEMPERATURE CHECK” is generated when a test is attempted. Wait for the instrument to ready itself. If it does not reach a ready state, contact the Crime Laboratory.

k. **RFI DETECTED** – An antenna wire in the breath hose monitors the environment around the DMT for elevated levels of radio frequency. If the radio frequency level exceeds the RFI limit, the message “RFI DETECTED” will be generated. Remove cell phones, hand held radio, any blue tooth connected device from the immediate testing area. Repeat the breath test. If the error persists, contact the Crime Laboratory.

l. **INCOMPLETE SAMPLE** – If the required breath sample parameters are not met during the 2 minute breath sample window, the message “INCOMPLETE SAMPLE” will be generated. This message is not generated if it is determined to be a refusal. Repeat the breath test or draw blood.

m. **FILTER WHEEL ERROR** – Two optical sensors are used to validate proper positioning of the filters and quartz standard in the optical path. The software monitors the movement of these wheels and if there is misalignment during any of the movement sequences, the message “FILTER WHEEL ERROR” is generated. If encountered, contact the Crime Laboratory.
n. INHALATION DETECTED – The instrument has a mass airflow sensor, which can determine the direction of airflow. If it detects an airflow in the reverse direction (e.g. the subject is inhaling back the breath sample recently provided), the message “INHALATION DETECTED” will be generated. The breath test will be aborted and the Breath Alcohol Analysis Report will be printed with the status message “INHALATION DETECTED.” Repeat the breath test and instruct the subject to blow inhale calmly and continuously blow until out of breath.

o. INTERFERENCE DETECTED – Each sample measured by the Intox – DMT is done so to determine the ethanol concentration. In addition, by measuring the sample at 3 wavelengths, we determine whether or not the sample is specific to ethanol. If a discrepancy is found compared to what is expected at the three separate filters, the sample is said to be non-specific to ethanol and the message “INTERFERENCE DETECTED” is generated. The Intox – DMT will terminate this test and a Breath Alcohol Analysis Report is printed with the “INTERFERENCE DETECTED” message. A possible cause of this message is the presence of another volatile substance, such as methanol or isopropanol, in the breath. Collect a blood sample in lieu of a breath sample.

p. STATIC ANALYSIS ERROR – When the sample has been accepted and is being analyzed, it is in the static state, and a valve closes off the breath tube from the sample chamber. In the event that the perceived alcohol value changes from the beginning of measuring the static sample to the end, it is suspected there might be a leak or another undesired reason for this, and the message “STATIC ANALYSIS ERROR” is generated. If encountered, contact the Crime Laboratory.

q. SAMPLE AGREEMENT ERROR - There must be an agreement of 0.02 between any two subject breath results. If the results do not meet the 0.02 agreement, the instrument will require a third subject breath sample. If there is an 0.02 agreement between any of the three tests, it is a valid breath test. If there is no 0.02 agreement between any of the three subject breath results, the instrument will print a test card that indicates "Sample Agreement Error." Repeat the subject breath test after a 15 minute waiting period or draw blood.

r. TANK PRESSURE TOO LOW - The Intox-DMT will only allow a breath test to be administered if there is adequate PSI for the external dry gas standard. If the PSI is too low to complete a breath test, the message "Tank Pressure Too Low" will appear on the screen when an Operator initiates a breath test. If this occurs, a new dry gas standard needs to be installed by the Crime Laboratory. If encountered, contact the Crime Laboratory.

K. Precautionary Checklist
L. Advisory Concerning Sanitary Practice During Administration of Breath Alcohol Tests

1. The following is taken from an advisory released by THE FOOD AND DRUG LABORATORY BRANCH of the CALIFORNIA DEPARTMENT OF PUBLIC HEALTH.

   a. Persons administering breath alcohol tests should recognize the possibility of acquiring or transmitting infectious diseases as a result of handling mouthpieces. The procedures employed to eliminate this possibility include:

      i. The operator must use a new mouthpiece for each breath test. The plastic bag enclosing the mouthpiece is opened at one end. The distal end of the mouthpiece exposed from the plastic is then inserted into the breath tube of the instrument.

      ii. The breath tube, with the mouthpiece attached, is handed to the subject by the operator. The remaining plastic is removed and the subject is requested to blow into the instrument.
iii. At the completion of the breath test the mouthpiece is removed and discarded by the operator. This is done using the plastic bag that originally contained the mouthpiece to avoid handling the mouthpiece directly.

M. Uniform Standard for Withdrawal, Handling and Preservation of Blood Samples for Forensic Alcohol Analysis

1. In accordance with Vehicle Code Section 23158(j), the Department of California Highway Patrol, in cooperation with the California Department of Public Health and the Department of Justice, has adopted uniform standards for the withdrawal, handling and preservation of blood samples prior to analysis. The standards are outlined below. The text has been modified for use in Contra Costa County.

2. Blood samples collected from persons involved in traffic accidents or traffic violations shall be collected, handled and preserved as required by Sections 1219 and 1219.1 of Title 17 of the California Code of Regulations.

3. Blood samples are collected by venipuncture from living individuals as soon as feasible after the alleged offense, and only by persons authorized by Section 23158 of the California Vehicle Code (i.e., only licensed physician and surgeon, registered nurse, licensed vocational nurse, duly licensed clinical laboratory scientist or clinical laboratory bioanalyst, a person who has been issued a “certified phlebotomy technician” certificate pursuant to Section 1246 of the Business and Professions Code, unlicensed laboratory personnel regulated pursuant to Sections 1242, 1242.5, and 1246 of the Business and Professions Code or certified paramedic acting at the request of a peace officer may withdraw blood for the purpose of determining the alcohol content therein. Alcohol or other volatile organic disinfectants are not used to clean the skin where a specimen is collected. Aqueous benzalkonium chloride (Zephiran), or Povidine-Iodine (Betadine) disinfectants are suitable to disinfect the skin before venipuncture.

4. Sterile, dry hypodermic needles and syringes or clean, dry vacuum type containers with sterile needles are used. No reusable equipment is used. The blood sample is deposited into a clean, dry container (such as VACUTAINER or VENOJECT) which is closed with an inert stopper. Sample containers are not reused. Tubes for collecting blood contain an anticoagulant (potassium oxalate) and a preservative (sodium fluoride). The minimum quantity of blood required to perform duplicate determinations by the laboratory and still provide sufficient quantity for referee analysis by the defendant is 3.0 ml.

5. Maintenance of identity and integrity of the sample, required by Section 1219 of Title 17 of the California Code of Regulations, shall include the following procedures:
   a. Label for Tube or Vial. The label of the blood vial or tube shall contain at least the following information:
      i. Full name of subject
      ii. Date blood drawn
      iii. Initials of person drawing blood
      iv. Initials of witnessing officer
   b. Envelope or Other Container Used for Enclosing and Identifying Blood Sample Tube or Vial from living individuals.
      i. The blood sample envelope or other container label shall include at least the following information:
         ii. Full name of subject
         iii. Submitting agency
         iv. Geographical location where blood sample was drawn, i.e., name and/or address of hospital, jail or other facility
         v. Name of person drawing blood sample
         vi. Date blood sample drawn
         vii. Time blood sample drawn
         viii. Signature of witnessing officer
ix. A form for establishing the chain of possession to be filled in by each person having possession of sample that includes "Received From" and "Received By" accompanied by a date.

x. Other information such as agency or laboratory number, offense charged, anatomical location from which blood sample was drawn, or any special instructions may be added.

6. Procedures for Obtaining Blood Samples from living individuals

a. The requesting officer must witness the withdrawal of the sample. When the officer witnesses the actual withdrawal of the blood, it may be unnecessary for the person drawing the blood to appear as a witness at the time of the trial.

b. The person drawing the blood shall fill out and initial the label and affix it firmly to the tube or vial. The sample shall then be given to the officer, who, in turn, shall initial the label and place the sample in the prescribed envelope or other container. The officer shall immediately complete the required information on the envelope or other container label and seal container securely.

c. A "Declaration" form is to be completed by the person collecting the blood sample. It will be distributed as follows:

i. White copy to the District Attorney's office

ii. Yellow copy retained in officer's report

iii. Pink copy to the person making the blood withdrawal

d. Appropriate steps to insure integrity of sample shall be taken.

i. Once the envelope or other container is sealed, it must not be opened except for analysis in the laboratory.

ii. Each person having possession of the sealed sample shall sign his/her name in the space provided for recording the "chain of possession."

N. INTOX-DMT Dual Sensor Operator Training Written Test (Time 25 minutes)

1. How long do state regulations (Title 17) require that the subject be under continuous observation before a breath sample is taken, during which time he hasn't ingested alcoholic beverages or other fluids, regurgitated, vomited, smoked or eaten?

a. 15 minutes

b. 20 minutes

c. 25 minutes

2. The INTOX-DMT uses which of the following methods for measuring alcohol concentration in the breath an

a. Infrared (IR) absorption method

b. an ultra-violet (UV) absorption method

c. an electrochemical fuel cell (FC) method

d. both (a) and (c)

3. If a problem occurs with the instrument during the evening hours, the trained operator can________________.

a. notify their superior to contact the Crime Lab during regular office hours

b. call the Crime Lab’s Alcohol Section phone number and leave a message

c. use a different agency’s/detention facility’s breath instrument or draw blood from the subject

d. all of the above

4. Which of the following is NOT an advantage for using blood to test for impairment?

a. blood can be reanalyzed at a later time
b. blood can be used to test for drugs, in addition to alcohol

c. blood requires a trained physician, nurse, or technologist to perform the withdrawal

d. blood alcohol is directly related to impairment

5. Which agency controls the regulations governing alcohol analysis, as found in the California Code of Regulations, Title 17?

   a. California Highway Patrol
   b. California Department of Public Health
   c. Department of Motor Vehicles

6. A valid breath test has a maximum allowable deviation of _________ between two breath samples taken from an individual suspected of driving under the influence of alcohol.

   a. 0.02 g/210L
   b. 0.03 g/210L
   c. 0.01 g/210L

7. The INTOX-DMT should always be left on?

   a. True
   b. False

8. What should an Operator do if the instrument displays “INVALID SAMPLE” during a breath test?

   a. Immediately start a new breath test
   b. Observe subject for another 15 minutes and then start a new breath test
   c. Nothing, it happens and doesn’t mean anything is wrong
   d. none of the above

9. The purpose/value of conducting an evidentiary breath test is to:

   a. Obtain a breath alcohol level
   b. Obtain a blood alcohol level
   c. Measure impairment
   d. Measure THC content

10. If the subject has alcohol in their mouth while giving a breath sample, the INTOX-DMT will display and printout a Breath Alcohol Analysis Report that indicates _________________.

    a. "BLOWING NOT ALLOWED"
    b. "AMBIENT FAILURE"
    c. “INVALID SAMPLE”
    d. "PURGE ERROR"

11. The officer is responsible for providing court testimony regarding _________________.

    a. the internal operation of the INTOX-DMT
    b. the regulations covered in the Title 17 Code of Regulations
    c. the operations involved in conducting the breath test

12. What should an Operator do if the instrument displays “STANDARD OUT OF RANGE” during a breath test?

    a. Try a breath test on a different agency’s INTOX-DMT or request a blood draw
    b. Contact your agency’s IT department
c. Nothing, even smart instruments can have gas problems
d. None of the above

13. The INTOX-DMT is designed to determine the alcohol level present in the ____________.
   a. mouth
   b. blood stream
   c. deep lung air

14. Persons authorized to supervise this course are ________________.
   a. Forensic Chemists
   b. Forensic Alcohol Analysts
   c. Forensic Pathologists

15. The green bar appearing at the bottom right corner of the visual display during a breath test indicates that ________________.
   a. the breath sample does not meet the minimum requirements
   b. the subject should stop blowing immediately
   c. an adequate breath sample is being delivered

16. After a breath test is completed, what is the proper procedure for the Operator to follow regarding the original Breath Alcohol Analysis Report?
   a. Sign and keep a copy for your records
   b. Forward the printout to DOPH
   c. Forward the printout to the Criminalistics Laboratory
   d. Give the print out to the subject

17. If three breath sample results are obtained and the values are:
   IR-0.15 g/210L     IR-0.18 g/210L     IR-0.16 g/210L
   FC-0.15 g/210L     FC-0.18 g/210L     FC-0.16 g/210L
   the INTOX-DMT will ________________.
   a. print out a valid test result
   b. require a fourth breath sample
   c. signal the operator to begin the test sequence again

18. The alveolar breath, which contains the __________ concentration of alcohol in the breath, will reflect __________ blood alcohol level of a subject.
   a. lowest, the true
   b. highest, a false
   c. highest, the true
   d. lowest, a false

19. An INCOMPLETE SAMPLE occurs when the subject:
   a. does not provide a sample within 2 minutes
   b. does not meet the minimum breath sample criteria
   c. inhales when asked to provide a breath sample
   d. both (a) & (b)

20. The correct manner for conducting a test on the INTOX-DMT is to ________________.
   a. practice running the instrument before testing
b. follow the Precautionary Check-list  
c. ask for assistance from other qualified operators  

21. During the 15 minute observation period, the subject is observed placing something into his mouth, the appropriate step is __________________________.
   a. to wait 5 minutes and then start the breath test  
b. request that a blood or urine sample be taken  
c. clear the mouth and wait an additional 15 minutes  

22. After the person withdrawing a blood sample fills out the DECLARATION, the signed copies are to be __________________________.
   a. released to the officer to keep in the report  
b. forwarded to the District Attorney for filing  
c. released to the person performing the blood withdrawal  
d. all of the above  

23. The INTOX-DMT is periodically checked for accuracy by __________________________.
   a. having alcohol-free subjects blow into the instrument  
b. using a device known as a Breath Simulator or dry gas unit containing a known alcohol concentration  
c. a California Department of Public Health technician  

24. It is the responsibility of the officer to witness the blood withdrawal in order to__________________.
   a. establish and maintain the chain of custody for the blood sample  
b. comply with the California Department of Public Health requirements  
c. release hospitals of any civil liabilities  

25. If the subject's breath contains acetone, the INTOX-DMT will __________________________.
   a. display "INTERFERENCE DETECTED" on the visual display, abort the test, and print a Breath Alcohol Analysis Report  
b. subtract the acetone level from the alcohol level  
c. display the "OUT OF MEASURING RANGE" on the visual display  
d. Not detect the acetone  

26. Where can a trained Operator obtain instructions for completing a proper breath test?
   a. Title 17  
b. The Precautionary Checklist  
c. Vehicle Code Book  
d. Google  

27. The INTOX-DMT uses which of the following criteria to determine deep lung air:
   a. flow rate.  
b. breath curve plateau.  
c. breath volume.  
d. all of the above.  

28. When the INTOX-DMT detects the presence of an interfering substance in the breath __________________________.

a. the instrument will display "INTERFERENCE DETECTED"
b. the test will be aborted
c. the instrument will display "INVALID SAMPLE"
d. both (a) and (b)

29. When blowing into the breath hose the subject should be told to ______________.
   a. blow as hard as one can
   b. blow into the hose for 10 seconds
   c. blow continuously until out of breath

30. What are the most important elements that should be included in a complete DUI investigation that a Criminalist could use to offer an informed opinion about impaired driving:
   a. The color of hair and eyes of the subject.
b. The drinking history (time of drinking) and the driving pattern.
c. The subject’s shoe size.
d. The performance on Standardized Field Sobriety Tests, the objective signs and symptoms, and chemical test results.
e. Both (b) and (d).

END OF DOCUMENT
I. Policy: The Alcohol Unit staff shall comply with all reasonable and legitimate Discovery Requests. (FSD.45).

A. Types of Discoveries:

1. The Alcohol unit provides "basic discoveries" or "extensive discovery" records related to subject breath tests.
   a. A "basic breath discovery" is a pre-set package that typically consists of:
      i. Instrument Maintenance Log (6-12 months before and after the incident date)
      ii. Accuracy Check Log (3 months before and after the incident date)
      iii. Subject Breath Test Log (1 month before and after the incident date)
      iv. Operator's Certification
   b. An "extensive discovery" is a request for more information than is included in the pre-set package of the "basic discovery". It may be a request for more detailed documentation to include but not limited to more extensive Instrument Records, Standard Operating Procedures, Proficiency Test Records etc. Once all required paperwork is received, the discovery request can be fulfilled.

B. Searching for the correct subject breath test information:

1. Finding the correct subject breath test information is dependent upon when the breath test occurred and which instrument the breath test was conducted on.
   a. If the subject breath test was conducted prior to January 1, 2009, the breath test information will be in the Drager Access Database (see Alcohol Unit Intoximeters DMT computer).
   b. If the subject breath test was conducted between January 1, 2009 and February 2018, search records in the Online Drager Database to generate records related to the Drager Alcotest MKIIIC (See online Intox DMT Database).
   c. If the subject breath test was conducted between November 2017 to the present, search records in the Online Intoximeters Database to generate
records related to the Intox-DMT Dual Sensor (See online Intox DMT Database).

C. Discovery Procedures:

1. The Clerical staff will create a discovery request in LIMS and image the request paperwork and deliver the requisite paperwork to the Alcohol Unit as described in CLER.DAT.12.

2. The analyst within the unit will review the discovery request and determine if further information is needed.

3. The discovery requests may be completed electronically and posted via ARIES.
   a. If the analyst is compiling the records on the Intox DMT Database Computer, see instructions for printing out discovery records from the Draeger Database Computer.
   b. If the analyst is compiling the records on a computer with a COPY of the Draeger Database, see instructions for printing out discovery records from a computer with a COPY of the Draeger Database Computer.
   c. The electronic files of the records requested will be gathered, concatenated and uploaded into LIMS. For detailed procedure on how to concatenate .pdf documents see "Electronic Batch Documents" under Tox.10.
   d. In the LIMS imaging module, right-click each image to be released as part of the discovery, and select "Send To iResults". A check mark will appear next to the "Send to iResults" menu.
   e. The discovery request will be marked as Draft Complete by the analyst compiling the discovery.
   f. The completed discovery will be checked and marked as Admin Reviewed by another analyst or by a Supervisor.
   g. The electronic discovery records will be accessible via ARIES for the District Attorney's office to retrieve. There is a 24 hour lag from the time the Case has been Admin Reviewed before the records will be accessible to the DA's office.

4. Any records not amenable to be uploaded into LIMS will be provided outside of ARIES.

5. Any "Rush" discoveries request may need to be provided as paper or faxed copy. The Rush discoveries need to be approved by the Supervisor to assess the exigency of the circumstances FSD.45

D. Instructions for printing out discovery records from the online Intox DMT Database.

1. Ensure the most recent downloaded information has been uploaded in the Intox DMT Database.

2. To obtain a “Basic” Breath Alcohol Discovery Packet or a Laboratory Copy of the Breath Alcohol Analysis Report:
   a. Go to the Intox DMT Database by going to secure intranet webpage found here: http://lab.so.cccounty.us/MuirLab/Account/Login
b. Login using your secure username and password provided by Technical Services.

c. Click on the **Intoximeters** instrument icon

d. Click the **Discovery** heading and select **Subject Related**.

e. In the search page your search criteria then click **Search** button.

f. When you find the desired record, click **Select**.

g. Select the report you wish and click **Display** Button.

h. Reports open as PDF files

3. To obtain the Operator Training Record for a specific Officer trained on the Intox-DMT Dual Sensor:

   a. Click the **Discovery** heading and select **Operator Training Record**.

   b. In the search field enter the operator’s name and click on the search icon or enter.

   c. When you find the desired record, click **Select**.

   d. Reports open as PDF files.

4. If you cannot find the desired records or need extensive discovery records:

   a. Click the Discovery heading select **Request More Information** and follow the instructions.

E. **Instructions for printing out discovery records from the Online Drager Database:**

1. Ensure that the most recent downloaded information has been uploaded into the Draeger Database.

2. Open the Draeger Database by double-clicking on the icon.

3. Log-in to the Database.

4. To obtain a “Basic” Breath Alcohol Discovery Packet or a Laboratory Copy of the Breath Alcohol Test Card click the **Discovery Documents** heading and select **Subject Related Documents**.

5. In the search field enter the subject’s name and search.

6. Find the desired record and click **Select**.

7. Choose the report by selecting either the **Breath Test Card** or **Basic Breath Discovery Packet**, click Display.

8. Print by clicking the **Print** Icon.

9. To obtain the Operator Training Record for a specific Officer trained on the Drager Alcotest MKIIIIC:

   a. Click the **Discovery Documents** heading and select **Operator Training Record**.

   b. In the search field enter the operator’s name and search.
c. Find the desired record, click **Select**.

d. Print by clicking the **Print** Icon.

F. **Instructions for printing out discovery records from the Drager MS ACCESS Database on the Intox DMT Database Computer:**

1. Open the Drager Database by double-clicking on the icon on the Home screen
2. Log-in to the Database
3. Click on Report Forms button
4. Click on Subject Related Reports
5. Highlight the Subject Field
6. Type the last name of the subject, first name
7. If the correct date and time automatically are listed, click the Time field and choose the matching date and time (pull-down box).
8. Click on Basic Discovery Reports for Basic Breath Discoveries or Click on Court Testimony Reports for records being taken to court or Drager 115.
9. Other reports on this window can be printed pertaining to the subject test listed in the Subject Test Field.
10. Officer training records can be accessed using the Officer Training Info query.

G. **Instructions for printing out discovery records from a computer with a COPY of the MS Access Drager Database:**

1. Ensure that the copy on the computer is recently updated by clicking on the Drager Back End Update icon.
2. Open the Drager Database by double-clicking on the Drager Records icon.
3. Log-in to the Database.
4. Click on Subject Related Reports.
5. Highlight the Subject Field.
6. Type the last name of the subject, first name.
7. If the correct date and time automatically are listed, click the Time field and choose the matching date and time (pull-down box).
8. Click on Basic Discovery Reports for Basic Breath Discoveries or Click on Court Testimony Reports for records being taken to court or Drager 115.
9. Other reports on this window can be printed pertaining to the subject test listed in the Subject Test Field.
10. Officer training records can be accessed using the Officer Training Info query.

H. **For handling of Civil discoveries, and Subpoena Duces Tecum**, see [FSD.45](#) and [CLER.DAT.12](#).

I. **For DMV SDT hearing discovery requests** follow [BA.36](#) & [FSD.45](#) in obtaining the correct DMV SDT request form, completing the discovery properly, and distributing the
records to the appropriate party.

END OF DOCUMENT
I. Policy: All equipment used for alcohol analysis is kept in good working order and routinely checked for accuracy and precision by a Laboratory authorized analyst.

A. State regulations require that only those models of breath instruments approved by the U.S. Department of Transportation may be used by law enforcement to test the breath of drivers for alcohol. Only such types and models of instruments and related accessories as are named in the "Conforming Products List" published in the Federal Register by the U.S. Department of Transportation shall be used for breath alcohol analysis in this state. The Alcohol Unit is furnished with the equipment for the analysis of alcohol in breath samples. This equipment includes:

1. The Intoximeters, Intox-DMT Dual Sensor with an integrated dry gas compartment (Intox-DMT) will be used for the analysis of breath samples in places other than the forensic alcohol laboratory and by Laboratory authorized personnel only when such places and persons are under the direct jurisdiction of a governmental agency or the forensic alcohol laboratory.

2. USB ethernet adapter (TRENDnet USB to 10/100 Mbps Adapter, Model TU2-ET100) for use with the Intox-DMT.

3. A personal computer equipped with a modem, SFTP access, Windows operating system, DMHost retrieval software, and a data base application such as SQL

4. A Breath Alcohol Simulator (Guth Model 34C, Guth Model 2100, Guth Model 12V500 or equivalent) or an Uncorrected Dry Gas Ethanol Breath Standard (EBS) cylinder (produced by Mid-America Airgas for Intoximeters, Inc.) is used to perform periodic determinations of accuracy (PDOA).

5. A temperature sensor serial data cable (either RS232 to RS232 for Guth Model 2100 or RS232 to 3.5 mm for Guth Model 12V500).

6. 2-D Barcode scanner (such as E-SEEK Model 260). The barcode scanner is an optional piece of equipment that may be used when an Intox-DMT is installed for service.

7. Eppendorf Pipettors, or equivalent, adjustable volume: 100 µl to 1000 µl and 500 µl to 2500 µl used to prepare solutions.

8. Balance, Analytical, capable of weighing 0.1 mg

10. NIST Thermometer
11. NIST Barometer

B. Before being placed into service (to perform casework/analysis), equipment calibration should be checked to establish that it meets the laboratory's requirements.

C. Each piece of equipment and its software significant to the test result in the alcohol unit should be uniquely identified.

D. For information about Balances, Pipettes (Variable Eppendorf or equivalent), Glassware, Thermometers, and Barometers see the Blood Alcohol Technical Unit Manual.

E. Equipment that needs repair shall be taken out of service. It shall be clearly marked or labeled as being out of service until it has been repaired and/or shown by calibration checks or test to perform correctly. If there is a concern that the defect affected previous tests, the laboratory shall investigate.

F. Test equipment should not be handled such that the calibration is compromised. If any damage, malfunction, or repair is needed the equipment will not be used for casework until remedial action is taken.

G. Repair and Other Services

1. Forensic Services Division staff has been trained in simple repairs of breath instruments and breath alcohol simulators. More complex problems may require removing a breath instrument and sending it to the manufacturer. The cost of repairs to equipment, which does not belong to the County, will be paid by the agency.

2. When an instrument must be removed for repairs, another instrument will be placed into service if one is available. When there are multiple malfunctions at several sites, a replacement instrument may not be available.

3. When instrument malfunctions do occur, the instrument may become disabled. The operator experiencing the problem should contact the Drugs, Alcohol, and Toxicology Section, Forensic Alcohol Unit by calling 925-313-2844. If an analyst is not available, a message needs to be left on the voice mail. Very often it is possible to resolve the instrument problem over the phone. If not, it is still important for a laboratory staff member to discuss the problem with the operator experiencing the problem in order to perform the proper repair.

4. Instrument service and repairs will be performed by a qualified laboratory member or by an Intoximeters, Inc. certified technician. Any service performed will be documented in the instrument's maintenance log.

5. When performing ANY special functions on the Intox-DMT breath instruments manually or remotely, service notes are needed to explain each special function performed or any results obtained.

H. Accommodations and Environmental Conditions

1. The laboratory is in a climate controlled building and the lighting and energy sources are suitable for the equipment in the Crime Lab.

2. Reference materials that require refrigeration are stored refrigerated and the refrigerators are monitored.

3. Analysts are responsible for maintaining a clean work area and general lab cleanliness. Trash is picked up from the lab and routine cleaning is performed by
General Services Department (GSD). Non-routine cleaning (eg. floor waxing, etc.) has to be specifically scheduled with General Services Department (GSD)

I. The following is a list of common notes entered WHEN APPROPRIATE for each function performed:

1. **Accuracy Check:**
   a. Pass
   b. Pass-Install check
   c. Pass-High SOLN ACC Check
   d. Pass-Low SOLN ACC Check
   e. SIM not at equil-see repeat test
   f. Pass-Removing instrument

2. **PDOA:**
   a. Notes are automatically populated by DM Host software
   b. Add notes to Maintenance Log if necessary

3. **Maintenance Test:**
   a. Pass-Annual Maintenance and the analyst's initials
   b. Pass-3 month maintenance
   c. See repeat test

II. **The Intox-DMT Dual Sensor uses Windows CE based software. A secure password must be entered to access technical functions and menus.**

   A. To access the various menus on the Intox-DMT, tap the Intox-DMT button located at the top left corner of the home screen. Most fields are editable by Crime Lab staff and may be changed if necessary. Refer to [ALC.40](#) for settings for normal operation of the instrument.

   1. **Setup (F1)**
      a. DMT
         i. Serial Number: Instrument serial number - not editable by Crime Lab staff
         ii. Title: Intox-DMT
         iii. Location: see [BRA.04](#) for a list of sites
         iv. Altitude
      b. Units
         i. Alcohol: g/210L
         ii. Pressure: mmHG (cannot be edited)
      c. Simulator
         i. Tolerance Check
ii. Standard Type

iii. Nominal

iv. Digital Simulator

END OF DOCUMENT
I. Policy: The training protocol for forensic alcohol analysis (breath) will be used to train Criminalists in the knowledge, skills and abilities prior to being authorized to perform instrument maintenance, review of instrument accuracy results, and perform operator training for breath alcohol testing.

A. Introduction - The Laboratory maintains the county's program for evidential breath alcohol testing adhering to Title 17 of the California Administrative Code of Regulations. Criminalists who have successfully completed breath alcohol training offered by the Laboratory will have acquired the knowledge, skills, and abilities to be authorized by the Laboratory to help maintain the breath alcohol program.

B. Expectations

1. The goals of the Breath Alcohol Training Program are to:
   a. Develop knowledge, skills, and abilities in the area of breath alcohol analysis and be proficient in all the tasks and assignments in this area of expertise
   b. Understand and implement the policies and procedures in the Breath Alcohol Technical Unit manual and Division Manual
   c. Gain expertise and knowledge and use of instrumentation culminating in the ability to troubleshoot and perform routine maintenance on instrumentation
   d. Gain expertise in courtroom testimony through experience

C. Purpose

1. The training will minimally address the following topics
   a. California Department of Public Health (CDPH) Regulation: The laboratory's forensic alcohol program is reviewed by the CDPH and regulated by Title 17. All analysts working in the breath program will read and follow:
      i. Title 17. Public Health. Group 8. Forensic Alcohol Analysis and Breath Alcohol Analysis. Articles 1-7
      ii. Laboratory of Forensic Services Breath Alcohol Operating Procedures
      iii. All field operators of the laboratory's breath instruments are trained by laboratory personnel. The CDPH recognizes instructors who are Forensic Alcohol Analysts as authorized by the Laboratory.
iv. How to deliver training to prospective field operators, including the following:

1. Value and purpose of forensic alcohol testing
2. General processes of absorption, distribution, and elimination of alcohol
3. Theory of breath alcohol analysis
4. Discussion of the requirements of Title 17 which includes the 15 minute waiting period
5. Methods of breath alcohol testing
6. How to administer the required written and practical examinations and evaluate results

b. Knowledge

i. Breath Alcohol Technical Unit Manual
   1. Breath Operator Training

ii. Understanding and application of Title 17

iii. Studying basic scientific principles upon which analysis is based

iv. Reviewing relevant literature

v. Reviewing procedures generally accepted in the discipline

vi. Attending outside courses, meetings and workshops, when possible

c. Learning specific procedures used in the laboratory

i. Learning the use and limitations of instruments

ii. Learning possible sources of error

d. Practice

i. Performing specific tasks under supervision
   1. Instrument verification
   2. Instrument installation/removal
   3. Instrument maintenance
   4. Maintaining instrument related records

ii. Performing training exercises

iii. Take the INTOX-DMT Dual Sensor Operator Training course as a student

iv. Assist in teaching the Operator Training course with the trainer

e. Interpretation and Testimony

i. Observing experienced analysts testify
D. Education

1. Criminalists working in the Alcohol sub-discipline shall possess a baccalaureate or an advanced degree in natural science, criminalistics or a closely related field. In addition, the analyst will meet the qualifications of Title 17.

E. Training Binder

1. The appropriate training records will be placed in the employee's training file maintained by the employee and reviewed by the Manager/Supervisor upon completion of the training:

   a. A summary of the training plan submitted to the Manager/Supervisor includes
      
      i. Topic(s)
      
      ii. Number of practice exercises. For example: maintenance tests, breath instrument adjustments, review of test results, etc.
      
      iii. Record of time committed to training
   
   b. Verification that the training and assessments were successfully completed
   
   c. Copies of certificates from courses taken
   
   d. Breath Alcohol Training Checklist ALC.35

F. Effectiveness

1. The training programs may evolve as needed with the addition of new instrumentation/techniques. The effectiveness of the training program will be evaluated when the Breath Alcohol Technical Unit Manual is periodically evaluated and additions or deletions to the training program will be documented. The following are all the training actions and can be used to evaluate the effectiveness of training:

   a. On-the-job training as indicated in the documented training program
   
   b. Review of the Unit SOP as well as training materials indicated in the documented training program
   
   c. Practical and written exercises as indicated in the documented training program
   
   d. Goals set for the analyst to increase responsibility, technical expertise, knowledge and skills as indicated in the documented training program
   
   e. Court training (mock court exercises, as applicable) and court critiques
   
   f. Ongoing training, including outside training classes, yearly performance evaluations that include setting of goals for the analyst, review of Statement of Qualifications and training binder. This assessment reviews analyst goals for development and evaluates the effectiveness of training actions and if further training actions are needed.
2. Assessment: The trainee will work under the close supervision of a trainer designated by the Manager/Supervisor. The trainer, an analyst with experience in the breath alcohol program, is responsible for coordinating the training as well as monitoring and assessing the trainee's progress.

   a. The trainee may not, without supervision, perform any task until training in that task has been successfully completed and the trainer has assessed the trainee. See Breath Alcohol Tasks Checklist below for documentation of the trainer's authorization for the trainee to perform specific tasks.

   b. The trainee who meets title 17 requirements may independently perform tasks for which training has been successfully completed and assessed prior to completing the entire program.

   c. The trainer will observe the trainee teach the course program and approve when they can independently perform the task. The approval should be documented on the Breath Alcohol Tasks Checklist.

      i. Copies of the trainee's practical and written examination (generated when taking the operator's course as a student) may be retained by the trainee.

   d. Operator Certification

      i. After successful completion of the Operator training, the trainee will be issued a certificate or Operator Card by the Laboratory. The certificate will indicate the operator's name, ID/Badge #, agency, and include the instructor's name.

      ii. Operator cards can be issued to trained officers. See CLER.DAT.11

3. Refer to the Division Manual (FSD.21) for further information regarding training.

G. References

1. Trainer will review the references available and their locations with the trainee.

2. The location of the references may be within the Alcohol Unit, the Laboratory library, in PowerDMS, and/or electronically available to each trainee (ALCO.211).

3. In addition to the specific references listed in each training Module, the trainee should also understand the following:

   a. Title 17-pertaining to Forensic Alcohol Analysis
   b. Blood Alcohol Technical Unit Manual (BA)
   c. Forensic Services Division Procedures (FSD)
   d. QA Procedures (QA)

II. Module 1: Historical Perspective on Breath Alcohol Analysis

A. Objectives/Topics of Study

1. Theory

2. Single vs. Dual Technologies

3. Fuel Cell and Infrared Technologies
4. Title 17
5. Basic Physiology (2100:1)
6. Preliminary Alcohol Screening device vs Evidentiary Breath Alcohol Instrument
7. General Forensics
   a. Analysts should develop a general knowledge of other forensic disciplines that may often be related to evidence processing such as:
      i. Latent prints
      ii. Biology/DNA
      iii. Toxicology
         1. Toxicology involves drugs, uses similar instrumentation and is often related to drug cases. Analyst should have an understanding of the differences in analysis, how instruments are used and reporting of results for toxicology evidence compared to drug evidence.
      iv. Firearms
   b. This knowledge may be obtained from a variety of sources
      i. Formal education in Criminalistics or Forensic Science
      ii. Supplemental reading of general forensic texts
      iii. Observation of analysts in other disciplines at the laboratory
      iv. Certification that has a general knowledge requirement

B. References
   1. Technology of Breath-Alcohol Testing
   2. Physiological Aspects of Breath-Alcohol Measurement
   4. Fuel Cell Technology
   5. A Historical and Experimental Study of the Breath Blood Alcohol Ratio
   6. General Forensics See BA.45

C. Study Questions
   1. What is the difference between an evidentiary breath test and a preliminary alcohol test?
   2. What are some physiological aspects associated with breath testing? How do they affect a breath test?
   3. Who developed the first roadside breath-testing device? Please describe.
   4. What is a breath alcohol instrument measuring?
D. Assessment

1. Trainer, or designee, will review and assess the answers provided by the trainee for the study questions. Written feedback will be provided to the trainee.

E. Documentation

1. Answers to the Study Questions must be submitted to the Trainer, or designee, for review. Include this document in the analyst's training binder.

2. Complete applicable sections of the Authorization Checklist ALC.35.

III. Module 2: Intox-DMT Dual Sensor Technical Training

A. Objectives/topics of Study

1. Fundamental concepts and theory of operation of the Intox-DMT Dual Sensor
2. Specificity and Interference
3. Methods of analysis and criteria for valid results
4. How to use the instrument to effectively perform accuracy checks, PDOA's, adjustments, maintenance tests, and installation of the Intox-DMT for service at agencies or training
5. Understand "Status Messages" and "Error Codes"
6. Understand and identify physical components of the Intox-DMT
7. Dry gas standards and simulator solutions used for adjustments and any type of accuracy check

B. References

1. Intoximeters, Inc. Intox DMT Dual Sensor Technical Training manual
2. Intox-DMT Dual Sensor Technician training power point presentation

C. Study Questions/Practical Exercises

1. What is the main principal that makes breath testing possible?
2. What are the dual technologies employed by the Intox-DMT Dual Sensor? How do they analyze a sample introduced into the instrument?
3. Describe the criteria for a valid analytical result.
4. When should an adjustment be performed on an Intox-DMT?
5. What is the accuracy of the Intox-DMT?
6. How does the Intox-DMT recognize interference?
7. Generate a copy of the calibration factors associated with the last adjustment done on an Intox-DMT. What do each of the items listed represent?
8. When possible, observe an FAA performing an adjustment and a verification on the Intox-DMT.
9. Review a copy of a COA for a dry gas standard and understand the information being provided.

10. With an FAA, open the lid of the Intox-DMT and identify the IR bench, filter wheel, and fuel cell.

11. List three status codes or error messages that may be encountered when using the Intox-DMT. Provide a brief explanation of each.

12. Why it is necessary to perform an in-house verification on an instrument when it is received into the Lab?

13. Explain how to correctly download information from the Intox-DMT to DM Host. Start with the IP address on the Intox-DMT.

14. Why is uncorrected dry gas used with the Intox-DMT?

D. Assessment

1. Trainer, or designee, will review and assess the answers provided by the trainee for the study questions and practical exercises. Written feedback will be provided to the trainee.

E. Documentation

1. Answers to the Study Questions/practical Exercises must be submitted to the Trainer, or designee, for review. Include the document in the analyst's training binder.

2. Complete applicable sections of the Authorization Checklist ALC.35

IV. Module 3: Breath Analysis

A. Objectives/Topics of Study

1. Solutions

   a. Preparing Reference Solutions

   b. Periodically checking reliability of Reference Solutions

   c. Determining correct concentrations of the solutions

2. Instrumentation

   a. Instruments used by the Laboratory for breath testing. The instruments are located at designated agencies throughout the county.

   b. External and internal parts of the breath instruments

   c. Equipment used to make repairs

   d. Routine maintenance procedures

      i. Three month maintenance

      ii. Service Checklist/Annual Maintenance ALC.42

   e. Breath alcohol instrument "Service Calls" and instrument repair (Including forwarding to manufacturer and verification upon return)

   f. Basic electronic and mechanical repairs
g. DUI Checkpoint and other "Special" breath instrument installations
h. Interference (How does it detect?)
i. Mouth Alcohol (How does it detect?)

B. References

1. The trainee will read extensively in all sections from the alcohol literature collection. Hard copies of journals, text books, and various reference materials are located in the laboratory's library. Electronic copies of select articles are located in PowerDMS. Any desired materials not present in the lab can be acquired upon request and approval.

2. CPDH Regulation: The laboratory's forensic alcohol program is reviewed by the CDPH and regulated by Title 17. All analysts working in the alcohol program will read and follow:

   a. California Code of Regulations, Title 17, Public Health, Division 1, State Department of Health Services, Chapter 2, Laboratories, Articles 1-7
   b. A written exam covering required topics as stated in Title 17 will be completed successfully prior to the alcohol impairment mock court.

3. The following are suggested readings and reference materials for the breath alcohol training program:

   a. AW Jones, Physiological Aspects of Breath Alcohol Measurement, National Laboratory of Forensic Science, Alcohol Drugs and Driving, Volume 6, Number 2, 1-25
   e. James G. Wigmore, Wigmore on Alcohol: Courtroom Alcohol Toxicology for the Medicolegal Professional, Irwin Law, Toronto, Ontario, Canada, 2011
   f. Blood Alcohol Technical Unit Manual: Literature References
   g. Binder 1 "Blood and Urine Articles"
   h. Binder 2 " Breath Section"
   i. Binder 3 " Impairment Sections"
   j. Binder 4 "General and Coroner"
   k. Equipment and Draeger Function Settings
   l. Maintenance Test
m. Multi-level check
n. Installation of Breath Instrument Technician Procedures
o. DUI Checkpoint Procedures
p. Breath Alcohol Technical Unit Manual
  i. General Requirements and Procedures for Periodic Determination of Accuracy
  ii. Analysis of Reference Solutions
  iii. Gaseous Ethanol Breath Standards (EBS)

4. The following are mandatory readings and reference materials for lab procedures and general alcohol impairment:
   a. California Code of Regulations, Title 17, Public Health, Division 1, State Department of Health Services, Chapter 2, Laboratories, Articles 1-7
   b. The laboratory's Blood Alcohol Technical Unit Manual
   c. Breath Alcohol Technical Unit Manual
   d. ALCO.211 in PowerDMS is a list of required references for alcohol impairment (highlighted titles are mandatory).
      i. Chapters 1-7 with reference pages of note: 90, 94, 98, 100, 105-106

C. Study Questions/Practical Exercises
   1. Attend breath instrument Operator Training
   2. Practical Exercises for Maintenance of Instruments
      a. Performing manual accuracy checks
      b. Changing reference solutions
      c. Checking function settings
      d. Placing an instrument in service
      e. Removing an instrument from service
      f. Restocking supplies including replacing printer ribbon and paper, if necessary
      g. Performing sample tests, diagnostics, and time, date, and location changes
      h. Equipment and Function Settings
         i. Maintenance test
         j. Multi-Level check
      k. Breath Alcohol Instrument Installation Technician Procedure
         l. DUI checkpoint procedures
3. Practical Exercises for Preparation of Reference Solutions
   a. Prepare a reference solution and record in the reference solution Preparation Log
   b. Determine the concentration of the solution by DCGC/FID
   c. Record the results

4. Study Questions
   a. Breath Alcohol Analysis
      i. What safeguards are employed by the breath instrument to ensure a reliable result?
      ii. Can the instrument detect other volatile compounds?
      iii. Does the instrument detect acetone?
      iv. If an individual blows 0.08%, 0.08% BrAC. What would their blood alcohol concentration be?
      v. What correlation ratio is the INTOX-DMT set at? What is being correlated?
      vi. Is there a scientifically accepted range for blood/breath correlation ratios?
      vii. Is there a difference in the concentration of alcohol between arterial and venous blood during absorption? During elimination?
   b. Breath Results
      i. Describe the procedure that an operator should follow to obtain a proper breath test.
      ii. What is mouth alcohol? How does the instrument detect mouth alcohol? What other precautions do we have to ensure that the breath result is not affected by mouth alcohol?
      iii. Explain what the instrument prints on the card associated with the breath test.
      iv. If the results are 0.08%, 0.10%, could the subject be as low as 0.07% and as high as 0.11%?
      v. Are the breath hose and sample chamber at room temperature? Why are they heated?

D. Assessment

1. The trainer will observe the trainee perform the functions identified above and approve when they can independently perform the tasks. This approval should be documented on the Breath Alcohol Tasks Checklist. The trainer will review the trainee's
   a. DCGC/FID results
   b. Reference Solution Preparation Log
2. Trainer, or designee, will review and assess the answers provided by the trainee for the study questions and practical exercises. Written feedback will be provided to the trainee.

E. Documentation

1. Answers to the Study Questions/Practical Exercises must be submitted to the Trainer, or designee, for review. Include this document in the analyst's training binder.

2. Complete applicable sections of the Authorization Checklist ALC.35.

V. Module 4: Data Handling

A. Objectives/Topics of Study

1. Periodic determinations of accuracy
2. Maintenance tests
3. General service and repair
4. Functional settings
5. General laboratory paperwork organization and filing

B. References

1. Breath Alcohol Technical Unit Manual
   a. General Requirements and Procedure for Periodic Determinations of Accuracy
   b. Analysis of reference solutions
   c. Gaseous Ethanol Breath Standards (EBS)
   d. Breath Testing Sites
   e. Maintenance Test
   f. Equipment and breath alcohol instrument function settings
   g. Database Procedures: Retrieving Data and Appending Tables
   h. DUI Checkpoint Procedures
   i. Installation of Intoximeter, Inc., INTOX DMT Technical Procedures
   j. Breath test records

C. Study Questions/Practical Exercises

1. The trainee will observe an experienced analyst during routine use of data handling for
   a. communications
   b. back-ups
   c. preparing reports for discoveries

d. review monthly INTOX DMT Logs for invoicing

2. Does the laboratory maintain a electronic record of these accuracy tests as a routine part of regular business procedures?

3. Does the laboratory have a procedure to handle apparent instrument malfunctions?

4. Does the laboratory keep records indicating call outs for apparent instrument malfunctions and subsequent repair of the instrument?

5. What is the path that any data takes starting with a breath alcohol test and ending with a discovery report in court?

D. Assessment

1. Trainer, or designee, will review and assess the answers provided by the trainee for the study questions and practical exercises. Written feedback will be provided to the trainee.

E. Documentation

1. Answers to the Study Questions/Practical Exercises must be submitted to the Trainer, or designee, for review. Include this document in the analyst's training binder.

2. Complete applicable sections of the Authorization Checklist **ALC.35**

VI. **Module 5: Database/Report and Notes**

A. Objectives/Topics of Study:

1. How breath alcohol records are stored by the Crime Lab

2. Maintenance Logs

3. Accuracy Logs

4. Subject Logs

5. Operator Training

6. How to generate breath alcohol discovery records

7. How to generate breath alcohol records for court or 115's

B. References

1. Breath Alcohol Unit Manual

2. **BRA.03**

3. **BRA.13**

C. Study Questions/Practical Exercises

1. How are weekly PDOA's downloaded and reviewed?

2. What are acceptable results for a PDOA?

3. How is a Basic Breath Discovery requested? When requested properly, how is a Basic Breath Discovery prepared?
4. What can be included in an extensive breath alcohol discovery?

5. Can an Intoximeters, Inc. Technician Training Manual or a Drager Instructor Training and Maintenance Manual be provided by the lab in a discovery? Why or Why not?

6. What is documented in the Maintenance Log for any given breath instrument? By whom?

7. What is an SDT? What is its purpose? Where can we find procedures to complete an SDT (be specific)?

8. What should be done by the Alcohol Unit before implementing a new version of software on a breath alcohol instrument?

9. What must happen when a discovery is prepared by an analyst before it gets sent to any attorney?

10. What steps should be taken when completing a discovery request from the SO Records Office? Private Attorney? DA's Office?

D. Assessment

1. Trainer, or designee, will review and assess the answers provided by the trainee for the study questions and practical exercises. Written feedback will be provided to the trainee.

E. Documentation

1. Answers to the Study Questions/Practical Exercises must be submitted to the Trainer, or designee, for review. Include this document in the analyst's training binder.

2. Complete applicable sections of the Authorization Checklist ALC.35

VII. Module 6: Legal/Ethics

A. Objectives/Topics of Study

1. Theory of operation of breath instruments
2. Practical operations of breath instruments
3. Instrument repairs
4. Record keeping
5. Operator training physiological considerations of breath testing
6. Effects of alcohol on the human body
7. Interpretation of blood/breath alcohol levels
8. Impairment of driving ability
9. Physiological action of alcohol
10. Pharmacology and toxicology of alcohol Laboratory methods of alcohol analysis
11. Instruments and procedures for breath alcohol analysis
12. Interpretation of results of alcohol analysis
13. Court decisions regarding chemical tests of alcohol to determine alcohol influence
14. Interferent
15. Medical issues
16. Alcohol impairment related to driving
17. Mathematical calculations of:
   a. approximate alcohol levels
   b. number of drinks consumed
18. Title 17 (sections related to alcohol testing)
19. The Laboratory's Breath Alcohol Technical Unit Manual and Blood Alcohol Technical Unit Manual

B. References
   1. laboratory Forensic Services Library
   2. Laboratory forensic Services Breath Alcohol Unit
   3. California Criminalistics Institute Library
   4. California State University Sacramento
   5. Professional organizations and contacts

C. Study Questions/Practical Exercises
   1. Courses
      a. Forensic Alcohol Supervisor Course - California Department of Justice, Bureau of Forensic Services (if offered)
      b. "The Robert F. Borkenstein Course on Alcohol and Highway Safety: Testing, Research, and Litigation" - University of Indiana, Bloomington, Indiana
      c. Courtroom Presentation of Evidence - California Criminalistics Institute
   2. Observation of drinking studies
   3. View subjects under the influence of alcohol:
      a. Ride-alongs with law enforcement
      b. Attend DUI checkpoints
   4. The trainee will be given the opportunity to practice before testifying. Possible practice situations include:
      a. participating as a witness in a mock trial arranged by the trainer
      b. answering questions on controversial court issues
      c. presenting relevant information to a non-technical audience
   5. Study Questions
a. What is the breath:blood correlation ratio used for breath alcohol analysis? Why is it important that it be set to that value?

b. What happens to a subject's breath alcohol level if they have a higher or lower correlation ratio? Explain.

c. If a subject refuses to give a breath alcohol result, and the agency obtains a forced blood draw, is the BAC compromised? Are there any concerns?

d. If the instrument fails a breath test due to Interference, and 5 min later, then gives a subsequent valid breath test? Are there any concerns?

e. If the instrument fails a breath test due to Mouth Alcohol, and 5 min later, then gives a subsequent valid breath test? Are there any concerns?

f. If the instrument fails a breath test due to No 0.020% agreement, and 5 min later, then gives a subsequent valid breath test? Are there any concerns?

g. If the PDOA after a subject breath test fails, is the subject breath test result in question? Why or why not?

h. If the maintenance check fails to trigger a mouth alcohol sensor during a maintenance check, are subject breath test results obtained prior to the maintenance test in question? Why or why not?

i. If a subject is viewed drinking while driving and pulled over at a DUI checkpoint, is there any concern about the breath alcohol test results for this subject if the test is done 5 min later? Why or why not?

j. What are the units of the breath test instrument results? How does it differ from a blood alcohol test result?

k. What is the level at which significant impairment occurs for MOST individuals? For ALL individuals? (Cite any sources)

l. If a person is in the elimination phase of their blood alcohol curve, how do their blood alcohol results compare to their breath alcohol results if they are taken at the same time? (Cite any sources)

m. How do FST's correlate to driving performance and driving impairment?

n. If someone performs well (little to no standardized clues noted) on the sFST's are they not too impaired to drive a motor vehicle?

o. If the DDA asks what a particular hospital blood alcohol level indicates, what concerns should you make them aware of when answering questions?

p. If PAS breath alcohol results are the only test results provided in court, what concerns should you make them aware of when answering questions?

q. If a subject has knee problems, how may that affect your opinion about their performance on FST's?

r. If a subject has a brain injury/condition, how may that affect your opinion about their performance on FST's?

s. How can you calculate the number of drinks in any individual if you know their BAC?

t. What is the average amount of alcohol in a drink? What is a standard drink?
u. Why is an Interference error message more common in higher BrAC readings?

v. What is the conforming products list and why is it important in breath alcohol testing?

w. What is an expert witness and how does it differ from any other type of witness in court?

x. What is important for an expert witness to do when testifying in court?

y. What role does the California Dept of Public Health have in alcohol testing?

z. List 5 different requirements for breath alcohol testing in Title 17?

D. Assessments

1. The trainee will observe and experienced analyst testify in breath alcohol trials. It is also recommended that the trainee observe:
   a. analysts testify in blood or urine alcohol trials
   b. defense expert testimony

2. Trainer, or designee, will review and assess the answers provided by the trainee for the study questions and practical exercises. Written feedback will be provided to the trainee.

3. Trainee readiness to testify will be assessed by the trainer with input from the unit supervisor and/or the person responsible for forensic alcohol analysis (as specified on the CDPH license). The approval should be documented on the Breath Alcohol Tasks Checklist.
   a. The analyst must meet title 17 requirements before testifying
   b. A written, "closed book" test will be administered covering requirements of Title 17 before authorization for impairment testimony will be granted.

4. Testimony evaluation
   a. When the analyst begins to testify, the unit supervisor or designee should accompany him/her to court to observe and evaluate the testimony.

E. Documentation

1. Answers to the Study Questions/Practical Exercises must be submitted to the Trainer, or designee, for review. Include this document in the analyst's training binder.

2. Complete applicable sections of the Authorization Checklist ALC.35

VIII. Module 8: Traceability

A. Objectives/Topics of Study

   1. NTRM (NIST Traceable Reference Material)
   2. Ethanol Breath Standards (EBS) dry gas
   3. Simulator Reference Solutions
4. Instrument Calibration Certificate
5. Instrument calibration adjustment

B. References
1. Quality Assurance in Breath-Alcohol Analysis
2. Reporting Blood and Breath Alcohol Results Statistical Aspects

C. Study Questions/Practical Exercises
1. Is there an uncertainty associated with a breath alcohol result? Why/why not?
2. Are reference solutions used for the breath alcohol program traceable? If so, which ones?
3. What is a COA and what information is included in a COA?
4. Why should NIST traceable solutions be used to make adjustments on the breath alcohol instrument?
5. Is a solution prepared by our Lab's Method NIST traceable?

D. Assessment
1. Trainer, or designee, will review and assess the answers provided by the trainee for the study questions and practical exercises. Written feedback will be provided to the trainee.

E. Documentation
1. Answers to the Study Questions/Practical Exercises must be submitted to the Trainer, or designee, for review. Include this document in the analyst's training binder.
2. Complete applicable sections of the Authorization Checklist ALC.35

END OF DOCUMENT
I. Policy: New instrument software must be validated or verified before use in casework or field testing for breath alcohol instruments.

A. Any new method, procedure, or adjustment to a current procedure must be tested in our laboratory to ensure that the method or procedure works as intended. The verification or validation shall be as extensive as necessary to adequately determine its fitness for purpose. The laboratory shall record the results and document the procedure. Approval of the method for use in casework is documentation that the method is fit for the intended use. See FSD.27.

B. A Validation/Verification plan will be generated, if necessary, then forwarded to the QA Coordinator for approval FSDF.20. Once approved, a Quality Action Validation/Verification request, or equivalent, can be generated and given to the Manager/Supervisor. Upon completion of the validation/verification it will be forwarded to the Quality Assurance Coordinator for review.

C. See the Division Manual policy for more information on validation/verifications FSD.15, QA.18, FSDF.20, and FSDF.12.

D. Software Revisions

1. The Intoxicimeters, Inc. Intox-DMT Dual Sensor breath alcohol instrument has software that runs the instrument and controls how the instrument interacts with the user based on its capabilities and settings. This instrument software may be revised to make changes to any of its functions that can improve the breath alcohol program.

2. When computers or automated equipment are used for the acquisition, processing, recording, reporting, storage, or retrieval of test data, the laboratory shall ensure that laboratory configured software is suitably validated and documented as being adequate and fit for use, as applicable.

3. When the software is revised by the laboratory, Intoxicimeters, Inc. performs the necessary changes to the software and provides the laboratory with a new revision number for the newly edited software. Evaluation software, where revisions are actively being made, will end in a number (43408-A10). The number may change depending on the number of revisions made during the evaluation. Software version 43408-A13 means there were thirteen revisions made from the original software version. Any software version ending in a letter (43408-B) means it has been evaluated, finalized, and is ready for use on the Intox-DMT.
4. Software revisions and the changes made in each revision will be documented by the alcohol unit.

5. Any validation or verification of the instrument software will be documented. The instruments with new software will not be used in the field until the documentation through the Quality Action Validation/Verification Request process is completed and documented by the Alcohol Unit and approved by the Quality Assurance Unit.
   
   a. Validation or verification may be done on "evaluation" software issued by Intoximeters, Inc. Once validation or verification is completed and approved, the final version of software will not have any additional revisions, except to update the unique identifier.

E. Guidelines for Performance Verification

1. The purpose of performance verification is to ensure that any new software, will work in our laboratory with our personnel and instrumentation.

2. A Verification plan will be submitted to the QA Coordinator for approval prior to beginning a verification. [FSDF.20]

3. Performance verification should consist of demonstrating that the software and instrumentation it runs on is able to process and yield the expected results. Prior to implementation of validated software, the reliability of the procedure shall be documented in-house against any documented performance characteristics of that procedure. Records of performance verification shall be documented ([FSDF.12]) and maintained in LIMS.

4. Qualified personnel criteria for a Performance Verification:
   
   a. For an instrument verification, an analyst who is competent in the unit can complete a performance verification.
   
   b. An analyst who is competency tested or in training can acquire data to be evaluated for the performance verification.
   
   c. For new technology (such as instrumentation), an analyst who is competent in the unit can complete a performance verification.

F. Guidelines for Method Validation

1. The purpose of method validation is to demonstrate that the method is suitable for the intended use and is reproducible by our laboratory's personnel with the use of our instrumentation.

2. A Validation plan will be submitted to the QA Coordinator for approval prior to beginning the validation. ([FSDF.20]) Plans may be updated as development proceeds, but must be resubmitted to QA for approval.

3. Method validation is required on new methods, methodology, or procedures. Validation is confirmation that the requirements for a specific intended use are fulfilled by examination of objective evidence.

4. Methods developed by the laboratory for its own use will be a planned activity and assigned to qualified personnel.
   
   a. Qualified personnel criteria for a Method Validation:
a. For a method validation, an analyst who is competent and currently proficient in the unit can plan and coordinate a method validation.

b. An analyst who is competency tested or in training (with supervisor/manager approval) can acquire data to be evaluated by a competent analyst for a method validation.

c. For new technology (such as instrumentation), an analyst who is competent and currently proficient in the unit can plan and coordinate a method validation.

G. Equipment

1. Equipment that is new to the laboratory shall be properly evaluated to ensure its reliability. The evaluation will be as extensive as necessary to meet the needs of the alcohol unit.

2. Before being placed into service, equipment shall be calibrated or checked to establish that it meets the laboratory's specification requirements. It shall be checked or calibrated before use in casework.

3. If the type of equipment already exists within the laboratory and additional equipment of the same type is obtained, a check of the equipment may be satisfactory to ensure its reliability. This check shall ensure that the equipment is operating properly. This will be evaluated by the Supervisor/Manager.

4. If the equipment is a new methodology or the operation is significantly different from equipment already in the laboratory, validation, training and an associated competency may be necessary. This will be evaluated by the Supervisor/Manager.

5. See BRA.16 for information on equipment.

END OF DOCUMENT
I. The goal of the Biology unit is to meet the needs of our customers in a timely manner and at the same time produce high quality work.

II. Case Submission Guidelines

1. All requests will be evaluated for appropriateness based on the capabilities of the Biology Unit. The Biology Unit reserves the right to determine if the service requested will or can be provided. The client agency will be consulted when the scope of the requested work cannot be met or needs to be changed.

2. When multiple clients are requesting services in the same case, the client responsible for the fees should be resolved, prior to commencing work.

3. Rush cases may be accepted after the reason for rush status is provided. Approval will be based on availability of laboratory resources, the type of case, and the reason for the rush request.

4. A completed laboratory request form is required for all requests for service.

5. The following information is needed for all cases:
   A. Evidence being submitted
   B. Where or who it was collected from
   C. How is it related to the case
   D. Type of service being requested (screening/DNA)

6. A police report or detailed synopsis is required for all Biology Unit examination requests. It helps evaluate what evidence offers the greatest potential for being probative, whether the evidence is eligible for CODIS, and from where the evidence was collected. The report also can convey timelines that may affect the quality or likelihood of results. For example, the time elapsed between the incident and the collection of evidence or whether a victim had consenting intercourse within last 72 hours.

7. DNA reference samples from victims, suspects, and consenting partners should be submitted at the time DNA testing is requested.

8. If the agency does not provide a police report or case synopsis, the necessary evidence, or the required reference samples, the case may be placed on hold until the missing items are received. Alternatively, the request may be returned to the agency.

9. For cases where charges are filed, permission must be obtained from the DA's office prior to consuming evidence.

10. Consideration should be taken to determine if the evidence may be amenable for testing by another unit. For example, an item with both smooth and textured surfaces may be suitable for latent print processing as well as DNA testing.

III. Case Prioritization

1. The Biology Unit strives to balance the needs of multiple agencies and the allocation of resources equitably. If the demand for services outpaces the availability of laboratory resources, the Biology unit will triage and prioritize case assignments. The prioritization is influenced by factors, such as seriousness of the crime, investigative need, and timelines.

2. The following list details how requests for biology examination will be prioritized. Those requests falling under Type 1 will be given top priority while request types 2 through 4 will be given priority accordingly.
   
   A. **Type 1**: Cases where there is an immediate Public Safety concern and there is a need to identify the perpetrator.
   
   B. **Type 2**: Cases where the investigator needs the assistance of CODIS to identify the perpetrator of a serous crime and no other probative evidence exists in order to arrest the suspect.
C. **Type 3:** District Attorney requires results in for filing charges, prosecution, or for a set trial date.

D. **Type 4:** Routine cases without any urgent investigation or court need will be worked in the order in which they were received.

IV. **Case Type Submission Guidelines**

1. The number of items accepted per examination request is based on the case type. A submission is defined as a package (i.e. bag, box, envelope). An item is defined as the contents within the submission. A submission may be comprised of one piece of evidence (i.e. one piece of clothing, swabbing of blood from a single area, or one weapon) or multiple items packaged together. Typically, the number of items in the package is considered to be the number of items submitted (i.e. pants, shirt and shoes), if all items are being examined.

2. For all case types, known DNA reference standards do not count against the number of items submitted.

3. If more items are submitted than the lab typically processes per request type, the evidence may be split into several requests. The Supervisor may discuss with the customer which item will be worked in each request.

4. The Supervisor is responsible for triaging and prioritizing requests. Other individuals within the unit may help in triaging and ensuring the laboratory has all information/evidence necessary to conduct the work. The number of items submitted per case should be adhered to; however, it is acknowledged that there will be cases that warrant an exception to the rule.

5. **Homicides:**
   
   A. The initial request for examination may be limited to 5 items. The investigating agency may have a conference with a Supervisor to discuss the case.
   
   B. If no probative results are found with the first set of items tested, a second request with five more items can be tested.

6. **Sexual Assaults:**
   
   A. The request for examination may be limited to 3 items. A sexual assault kit is considered one item. Typically, the first request should include the sexual assault kit.
   
   B. If the SAEK kit does not provide probative results, other items such as clothing or bedding may be examined in a subsequent request.
   
   C. The Biology Unit uses a Y-screening method to streamline the sampling and processing of sexual assault cases involving at least one female and at least one male individual (Refer to [BIO.2.DNA.02](#)). Cases which involve male-on-male sexual assault, or assaults with female perpetrators are not well characterized by this method. Alternatively, Sexual Assault Evidence Kits may be screened for biological fluids (Refer to [BIO.1.BIO.04](#) and [BIO.1.BIO.05](#)).
   
   D. If a body fluid is identified or male DNA is detected, DNA testing will be conducted and any generated profiles will be entered into CODIS within 120 days of receipt by the Laboratory.
   
   E. The sexual assault paperwork associated with qualifying sexual assaults will be reviewed for the following information:

   1. The type of penetration that occurred (e.g., vaginal, rectal, oral, digital, etc.)
   2. Whether ejaculation occurred
   3. Whether a condom was used
   4. Other activities (e.g., patient licked, kissed, bitten, etc.)
   5. Number of offenders
   6. If the victim was mentally impaired or may be under the influence of drugs and alcohol
   7. Whether unprotected consensual sex is documented within 72 hours of alleged assault

F. **Processing of Sexual Assault Evidence Kits using Y-screening**

   1. All evidentiary swabs contained in the sexual assault kit will typically be sampled and differentially extracted regardless of the type of alleged activity

   1. The non-sperm fraction may be taken forward for amplification without the sperm fraction if Y-screening indicates the majority of the male DNA is in the non-sperm fraction. However, if the sperm fraction is selected for DNA testing the non-sperm fraction will also be selected.

G. **SAEKs with an adult victim and a single assailant:**
1. If conducting body fluid identification, examine the swabs as necessary given the case history until probative evidence is found or those items have all been tested. If available information indicates that an assault does not involve certain areas on the victim’s body, examination is not required on the specified swabs.

2. For male DNA screening, if male DNA is detected in multiple samples only 1 or 2 samples where a sufficient amount of male DNA is detected need to be taken forward for amplification.

H. SAEKs with an adult victim and multiple assailants and who may be mentally impaired or may be under the influence of drugs and alcohol:

1. If conducting body fluid identification, examine all collected swabs in the kit.

2. For male DNA screening, all samples where a sufficient amount of male DNA is detected are to be taken forward for amplification.

I. SAEKs involving juvenile victims:

1. If conducting body fluid identification, examine all collected swabs in the kit until either probative evidence is found or reasonable test options have been exhausted.

2. For male DNA screening, only 1 or 2 samples where a sufficient amount of male DNA is detected need to be taken forward for amplification.

J. Examinations of the swabs contained in SAEKs collected greater than 72 hours may be conducted on a case by case basis depending on the case circumstances.

7. Persons Crimes (Robbery, Assault, etc):

   A. The initial request for examination may be limited to 3 items. Items typically submitted are bloodstains from the scene or on clothing, items left by the perpetrator (cigarette butt, item of clothing, or a weapon), and touch DNA swabs.

8. Burglary/Property Crimes:

   A. The initial request for examination may be limited to 2 items.

   B. The best type of evidence in these cases are bloodstains from the scene, or items left by the perpetrator (cigarette butt, an item of clothing).

   C. If touch DNA testing is requested, every possible effort must be made to collect elimination standards from individuals who have routine contact with the item before a profile from the of item will be entered into CODIS.

9. Weapons Possession Cases:

   A. Profiles generated from weapons possession cases are typically not allowed in CODIS. Reference samples from subject's in theses types of cases should be submitted to the Laboratory for comparison to any generated profiles.

10. Criminal Parentage Cases:

    A. Submissions must include a reference standard from the mother/alleged mother, father/alleged father, and the the child or products of conception.

    B. Products of conception should be frozen if the aborted fetus cannot be submitted to the laboratory within 1 week of collection. Due to the difficulty of recognizing fetal remains <8 weeks gestation, it is preferred that the products of conception be separated by medical personnel prior to being submitted to the laboratory.

    C. Cases with partial submissions will not be assigned, unless dictated by case circumstances (such as the mother is deceased or maternity is in question and the father is unknown).

END OF DOCUMENT
### Visual, Instrumental and Microscopic Examinations

**I. Examinations:** A visual examination is the most basic means of detecting potential biological evidence. Visual examinations need to be conducted prior to presumptive testing. A visual examination of the evidence should be conducted with the naked eye using natural light, bright light, and/or oblique lighting. Specialized lighting techniques, such as an alternate light source or an infra-red camera, may better resolve the contrast or definition of a stain, thus allowing for better detection of biological stains.

**II. Normal Room Light Examinations**

A. The quality of room-light illumination, both in intensity and color, is the single largest factor in locating biological stains without supplemental techniques. Lighting can be provided by small handheld lights or larger stand lights to illuminate an entire piece of evidence or scene. Direct lighting refers to lighting with no reflection. Light is shone straight onto an item or surface to provide illumination. Oblique lighting is a technique in which light is applied at an angle. Oblique lighting can provide contrast and shadowing effects which can be helpful with detecting hairs and fibers or hard-to-see stains on surfaces.

B. Biological stains may be visualized based on color or discoloration, or by textural differences with respect to the surface or background material, often referred to as the substrate.

**III. Alternate Light Source (ALS) Examinations**

A. Many biological stains, such as semen, saliva, and urine may fluoresce, or appear bright, when viewed with an ALS in a darkened room. However, a number of other materials also fluoresce, such as food and drink stains, laundry and cleaning products, and many other substances. Additionally, not all semen or saliva stains will fluoresce with an ALS. Blood will not fluoresce when viewed with an ALS; rather, it will appear dark.

B. **Equipment/Materials:**

1. 415nm and 450nm Handheld alternative light sources
2. Safety goggles (orange, red, yellow)
3. Dark room.

C. **Discussion:**

1. The biological fluorescence is always at a longer wavelength (less energy) than the incoming incident light, and is usually in the visible spectrum. The differentiation between the stain and the background material is highly dependent on the interaction of the biological substance and the substrate with the light source. The examiner is should explore using both the 415nm and 450nm wavelengths of incident light using appropriate goggle (barrier) filtration to determine the optimum differentiation needed for the evidence. A good starting parameter is 450 nm (blue) light with orange or yellow goggles.

2. The auto-fluorescence of the background material can be maintained while looking for biological stains that are quenching the fluorescence. The stains will appear as darkened areas instead of fluorescent. The location of suspected biological stains can be marked with ink or arrows for further testing. See presumptive testing protocols for blood, semen, and saliva.

D. **References:**

4. ROFIN Polilight-Flare Plus 2, User Guide

**IV. Alternate Light Source (ALS) Examination using the Leeds Spectral Vision**
A. Similar to what is described above, the Leeds Spectral Vision camera and light system can be used to simultaneously screen items for biological fluids and photographically document the findings. The location of suspected biological stains can be marked with ink or arrows for further testing.

B. **Equipment/Materials:**
   1. Leeds Spectral Vision system
   2. Safety goggles (orange, red, yellow)
   3. Dark room.

C. **Procedure:**

1. Turn on the camera system and the computer; double-click the Leeds Vision icon on the computer desktop to start the software. You will hear the camera and light components begin to self-calibrate.

2. Position the camera head over the evidence you wish to examine. White light with a clear filter is the starting point for the system.

3. Focus the camera on your item by zooming in completely, focusing, and then zooming out. The diopters can be increased or decreased based on the working distance of the camera to the evidence (note: focusing the camera needs only to be performed once for each light source at any given working distance. For example, if the working distance is increased or decreased by moving the camera arms, focusing will need to be readjusted. Also, the focus will need to be readjusted when switching light sources.

4. Overall photographs of the image using white light can be captured by clicking the "capture" button on the screen.

5. To switch to an ALS starting point, "Blue light/Orange Filter" can be chosen from the presets menu. This changes the light source to blue light at 455nm and an orange filter at 550nm (refocus the lens once the light source has been changed). The brightness, gain, and aperture can all be changed to get a more clear image (note: it is recommended to "screen" with a high gain for the speed of the camera. However, this introduces digital noise into the image. Reduce the gain before capturing a photograph).

6. Different lights and barrier filters can be chosen from the "Light/Filters" options on the right side of the screen to optimize imaging.

7. Stains can be zoomed in on and captured using the "capture" button. Additionally, images can be compared side-by-side by using the "tools" menu.

8. Save images as a .lsi file for opening in the Leeds Vision software, or export the images in another format (i.e. jpeg).

D. **References:**

V. **Stereo Microscopy**

A. The magnification provided by a stereomicroscope can provide an additional level of detail to an observation that may be beyond what the eye of the examiner can readily detect. This tool is useful when attempting to locate biological material or trace evidence that would not be seen with normal eyesight alone.

B. The stereomicroscope may be used at varying magnifications (typically between 5X and 30X magnification) as well as with various means of lighting (episcopic ring light for uniform lighting, or oblique lighting using adjustable light guides.) The stereomicroscope allows for 3-dimensional, fully rectified viewing of the object.

C. Suspected stains may be photographed using a digital camera attached through the phototube extension. Documenting the stereomicroscopic examination with notes and pictures can become very important for evidence, such as hair roots, small bloodstains, and other biologicals where consumption of the item is needed for analysis.

D. **Equipment/Materials:**

1. Stereo Microscope (Nikon SMZ or similar) or light microscope (Olympus BX41 or similar)
2. Light Source SLR (Single Lens Reflex)
3. SLR Digital Camera and SLR Adaptor

E. **Procedure:**

1. Attach the SLR adapter to the light beam splitter (found to the side or behind the oculars).
2. Attach an SLR camera to the adapter.
3. Adjust the focus of the microscope so that the image is in focus.
4. Slide the light beam splitter rod into the "camera" setting (if applicable).
5. Make necessary adjustments on the camera and take a picture.

3. Leica MZ8 Instruction Manual
4. Olympus BX41 or similar Instruction Manual

**VI. Infra-red Examination using the Leeds Spectral Vision**

A. This technique relies on the concept of an object, when illuminated by a light source, either reflecting and/or absorbing infra-red light. Some objects or materials may not reflect infrared light, but instead absorb (or "quench") the infrared light, causing it to appear dark gray or black in the image. Because the human eye does not detect wavelengths of light in the infra-red spectrum, a camera is used to capture the infra-red light reflected from an object. The reflectance and/or absorbance can be captured through a camera and monitored in real time on a computer monitor display.

B. Blood absorbs infra-red light. This technique is helpful in detecting the presence of blood on dark objects, such as on dark clothing when the dark background material reflects the infra-red light.
C. **Equipment/Materials**

1. Leeds Spectral Vision system
2. Safety goggles (orange, red, yellow)

D. **Procedure:**

1. Turn on the camera system and the computer; double-click the Leeds Vision icon on the computer desktop to start the software. You will hear the camera and light components begin to self-calibrate.

2. Position the camera head over the evidence you wish to examine. White light with a clear filter is the starting point for the system.

3. Focus the camera on your item by zooming in completely, focusing, and then zooming out. The diopters can be increased or decreased based on the working distance of the camera to the evidence (note: focusing the camera needs only to be performed once for each light source at any given working distance. For example, if the working distance is increased or decreased by moving the camera arms, focusing will need to be readjusted. Also, the focus will need to be readjusted when switching light sources.

4. Overall photographs of the image using white light can be captured by clicking the "capture" button on the screen.

5. To switch to the IR camera, "IR" can be chosen from the presets menu. This changes the light source to IR light at 850nm and a filter at 830nm (remember to refocus the lens once the light source has been changed). The brightness, gain, and aperture can all be changed to get a more clear image (note: it is recommended to "screen" with a high gain for the speed of the camera. However, this introduces digital noise into the image. Reduce the gain before capturing a photograph).

6. Additionally, sometimes the violet light at 400nm and the clear filter can be used to capture potential bloodstains. When using the violet light, make sure to wear the clear safety goggles.

7. Stains can be zoomed in on and captured using the "capture" button. Additionally, images can be compared side-by-side by using the "tools" menu.

8. Save images as a .lsi file for opening in the Leeds Vision software, or export the images in another format (i.e. jpeg).

E. **Discussion**

1. Not all dark fabrics will be amenable for the IR camera. Dark fabrics that appear white or gray with the IR camera will allow bloodstains to appear dark. In these instances, the bloodstains are absorbing the IR light. The fabric that appears dark or black with the IR camera is absorbing the IR light and will not lend itself for distinguishing the presence of a bloodstain.

2. The IR technique is not intended to replace a visual examination for blood under normal or other lighting techniques. The IR technique is amenable when searching for bloodstains on dark surfaces, however it is not adequate when searching for small bloodstains. The IR techniques should not be used in place of a stereomicroscope examination when searching for small bloodstains. Searching for small bloodstains, such as bloodspatter, needs to be conducted by a visual examination and a stereomicroscope.

VII. **Speckfinder**

A. The Speckfinder is a visual imaging system that uses high definition magnification to see precise details of objects and can save and process images for documentation. The Speckfinder completely integrates the technologies of high quality optics, digital cameras, LED lighting, glass displays, personal computing electronics, and mechanics, to produce a workstation-friendly computer video microscope. Images collected from the Speckfinder can be stored in multiple digital formats, networked, and software enhanced, as needed.

B. **Equipment:**

1. Dazor SpeckFINDER model HD-V2-SB1-LRS1

C. **Procedure:**

1. Set the object up on the speckFinderHD.
2. Turn on the speckFinderHD by pressing the circular button above the screen.
3. Log-in using user name and password.
4. Open the “Operator VIEWER” program. Once the program is open, full screen live view of the camera will be seen on the screen along with 4 buttons:
5. Focus the image, adjust base light and ring light, and adjust the zoom and aperture (on the barrel of the lens) for the desired picture. The ring light can be electronically adjusted using “RingLight Control” program.

6. Select a destination folder using the “save location” button. Once the desired picture is on the live view screen, click the “snap a picture” button.

7. Transfer the images via the USB ports located on the back of the unit.

8. Shut down the computer and hold the power button until the shutdown sequence is completed.

VIII. Microscopy and Cytological Staining of Biological Material

A. Microscopy is commonly used for biological examinations to help characterize cells such as epithelial cells, spermatozoa, and other materials such as hair or starch particles that are commonly encountered with sexual assault cases. Characterization of cells is often assisted with a cytological dye staining of the cellular material. Common microscopy methods used in biology include brightfield - generally used in conjunction with cytological staining methods, phase/contrast, and polarized light microscopy.

B. Cytological Staining for Glycogenated Cells

1. Vaginal secretions may be indicative of sexual activity or the result of normal discharge. Glycogenated epithelial cells are cells specific to vaginal secretions. Glycogenated cells contain glycogen, the principle storage form of glucose (sugar). The
presumptive test "Lugols" can test for glycogenated epithelial cells from vaginal fluid secretions.

2. Materials:
   a. Lugol's 10X Iodine Stock Solution (see reagent prep BIO.5.QAQCF.11)
   b. Microscope slides and cover slips and mounting medium
   c. Microscope (Bright field, Phase Contrast)

3. Procedure:
   a. Dilute Iodine Stock Solution 1:20 with deionized water. (Discard after use)
   b. Prepare a cellular smear using approximately 3 µl of cellular extract on a microscope slide (see Recovery of Protein/Cellular Material an Integrated Method for DNA Analysis, BIO.1.BIO.09)
   c. Dry the cellular smear and heat fix on a 56° C heat block.
   d. Apply sufficient working Iodine solution to allow coverage of the cellular material when a cover slip is applied.
   e. Apply a coverslip.
   f. Examine resulting cytological stain under bright field conditions at 200X.

4. Interpretation:
   a. Glycogen-positive nucleated squamous epithelial cells: Abundant (e.g. greater than 10% of cell counts) glycogen-positive, nucleated epithelial cells are indicative of cellular material of vaginal origin. The Iodine solution stains glycogen within the cytoplasm of cells a chocolate brown color, with the cell nucleus diagnosed either in bright field, or accentuated in phase-contrast.

C. Differential Cytological Stain for Spermatozoa and Epithelial Cells

1. Cellular material can be easily viewed under phase contrast without cytological staining. Though staining can be used with phase contrast, it typically is utilized when visualizing cellular material under bright-field microscopy.

2. Materials:
   a. Christmas tree stain (Serological Research Institute, R540)
   b. Solution A (Kernechtrot Solution, nuclear fast red)
   c. Solution B (Picroindigo carmine)
   d. Ethanol and deionized water
   e. Microscope slides and coverslips and mounting medium
   f. Microscope (Bright field, Phase Contrast)

3. Procedure:
   a. Use a dry-mount slide prepared by a Sexual Assault Nurse Examiner, or prepare a cellular smear on a microscope slide using approximately 3 µl of cellular extract (see Sampling and Protein/Cellular Material Recovery, BIO.1.BIO.09)
   b. If preparing from a cellular extract, dry the cellular smear and heat fix on a 56° C heat block.
   c. Apply sufficient nuclear fast red (Solution A) to fully cover the cellular smear and allow to sit for 5 to 10 minutes.
   d. Rinse Solution A from the slide with a gentle stream of deionized water. (Optional: dry the slide using a stream of warm air from a hair dryer.)
   e. Apply sufficient picroindigo carmine (Solution B) to fully cover the cellular smear and allow to sit for up to 1 minute.
   f. Rinse Solution B from the slide with a gentle stream of ethanol. Dry the slide.
   g. Cover the cellular material with a coverslip with either Permount or Cytoseal fixative, minimizing bubbles.
   h. Microscopically examine the stained smear using bright field (200 to 400X) and, optionally, using phase-contrast microscopy.

4. Interpretation:
a. **Differentially stained cells (Christmas tree Stain) - Bright field:** Nuclear material stains red, while cellular cytoplasm stains green to blue in color. Anucleated epithelial cells will stain primarily green in color, and will not have a red-stained nucleus. Nucleated epithelial cells will stain green to blue for the cytoplasm, and will have a red stained nucleus. Spermatozoa will have a red-stained body, with a lightly shaded acromere. The midpiece and tail, if present, will be darkly stained.

b. **Differentially stained cells (Christmas tree Stain) - Phase Contrast:** Cells will have a three-dimensional "raised" appearance, and the nucleus of epithelial cells will stand out as a cell organelle. Spermatozoa will appear as a two-toned oval body, with the acromere appearing dark, while the base of the cell will appear bright.

### D. Starch Particles - Polarizing Light Microscopy

1. Some condoms contain starch as a lubricant; however finding starch does not necessarily mean that a condom is the source of the starch. Some hygiene, laundry products, and food preparations also contain starch. Low levels of starch can naturally occur in the environment as well.

2. **Materials:** Microscope under dark field with polarized filters

3. **Procedure:**
   
   a. After Christmas-tree staining and under bright field conditions, starch particles appear as unstained, clear, and amorphous particles.

   b. Under dark field (cross polar conditions) the starch particles will appear as bright particles with a distinctive "Maltese Cross" through the center axis.

   c. If stained with Lugol's iodine solution, the starch will stain intensely blue when viewed under bright field conditions.

### E. Removing Biological Material from Mounted/Fixed Slides

1. Sometimes cellular material, desired for DNA typing, is fixed onto a glass slide. The following is a guideline for collecting or removing the material from a fixed slide.

2. **Equipment:**
   
   a. Xylene
   b. Dropper
   c. Forceps
   d. Petri Dish

3. **Procedure:**
   
   a. Examine the mounted slide to locate the desired biological material.

   b. If the sample is a hair root, use a scribe and cut a square into the slide cover around the root area. Be sure to cut an area large enough to include a portion of the hair shaft, as a control, and enough room to pull the hair out.

   c. Using forceps, remove the cut glass and discard into sharps container.

   d. Place slide into petri dish and working under a hood or in a well ventilated area. Add one to two drops of Xylene into the exposed square.

   e. Allow mounting medium to dissolve. Using forceps, grasp the hair shaft above the root and gently begin to remove the hair. If the mounting medium has not dissolved, add another drop of Xylene, let dissolve, and remove. Repeat as necessary.

   f. Once removed, cut the hair root and an equal portion of the shaft immediately above the root and place into separate tubes. Follow hair extraction protocol described in BIO.2.DNA.02.

   g. If the desired sample is cellular material fixed onto the slide, then submerge the entire slide in Xylene. Allow the mounting medium to dissolve. Check periodically for the cover slip loosening from the slide.

   h. When the mounting medium has dissolved, remove the slide from the Xylene and gently wipe away any residual Xylene and mounting medium. Slowly pry the cover slip from the slide. Add additional drops of Xylene if needed to remove the cover slip.

   i. With the cover slip removed, add a drop of Xylene onto the fixed cellular material. Wait approximately 1 minute to further dissolve any residual mounting medium in the area of interest.
j. Using a single sterile swab, vigorously swab the cellular material until completely removed from the slide.

k. The cellular material can then be extracted for DNA following the protocol described in BIO.2.DNA.02.

l. OPTIONAL: To ensure all mounting solution is dissolved on the swab, add 400 ul of Xylene into the 1.5 ml extraction tube with the swab head. Wait approximately 1/2-1 hour. Remove the substrate and place in a spin basket. Centrifuge at maximum speed for approximately 5 minutes. Remove all but 50 ul of the supernatant and discard, or transfer to another tube. Place the substrate back into the tube and begin with the DNA extraction protocol.

F. References

Blood is a mixture of liquid and solids. Serum is the yellow liquid portion in blood that contains the proteins for clotting, such as fibrin. The solid portion of blood is made up of red blood cells, white blood cells and platelets. Red blood cells deliver the oxygen to the rest of the body and carbon dioxide to the lungs. Red blood cells were used for prior serological forensic testing, such as ABO and enzyme typing. Red blood cells do not contain DNA. White blood cells (WBC), which function as part of the body's immune system, contain DNA. Because WBCs contain DNA, they are the most important part of the blood for DNA analysis. The quantity of WBCs in a drop of blood, however, is far less than the number of red blood cells.

### BLOODSTAIN EVIDENCE

Blood can be found at crime scenes particularly when the crime involves some type of bodily injury. There are times when the presence of blood can signal that a crime has been committed even in the absence of a body. Blood typically is easily visible and can be located due to its characteristic color. Conversely, when blood has been cleaned up, or has aged or degraded, it may be unrecognizable. Light sources, such as an infra-red camera can be useful to detect blood on dark surfaces. Refer to BIO.1.BIO.01 for visual examination with light sources.

Presumptive tests are used on visible suspected bloodstains, as well as, on visually faint or latent stains where blood is suspected to be present. Presumptive tests are considered "presumptive for the presence of blood" due to their potential for cross-reaction with other biological and chemical substances. A variety of catalytic (presumptive) tests are available. The catalytic test chosen to be used may depend on factors such as: stability of stock reagents, ease of preparation, chemical safety, sensitivity and specificity. The catalytic tests (Hemastix, orthotolidine, lecomaleichite green, and phenolphthalein) each utilize the same chemical pathway. All but the Hemastix test are a two-step chemical process. The two-step process guards against false positives that can occur with oxidizing substances, therefore the two-step catalytic tests are more specific for blood than Hemastix.

An immuno-chromatographic test for human hemoglobin (such as the ABAcard Hematrace Test, see below) is a presumptive test for human blood. This test, when paired with a catalytic test for the presence of blood, provides not only strong evidence for the presence of blood but strong evidence for the presence of "human" blood because few non-biological substances, if any, will provide both a positive catalytic test and a positive test for human hemoglobin.

Factors that can affect blood screening tests are age, temperature and possibly the substrate material upon which the blood is deposited on.

1. **Age**: When blood is fresh, it appears red to the human eye, but over time it will darken and become brown. As the color of the blood changes with age, so does its chemical composition. Hemoglobin will change to methemoglobin when exposed to air over a long period of time and the blood becomes insoluble over time. These visual and chemical changes will affect the test results, such as causing potential false negatives.

2. **Temperature**: Cold temperatures preserve blood longer allowing for presumptive tests to be conducted at a later time. Conversely, heat accelerates the chemical changes. Blood will degrade quickly when exposed to humid climates (moist and warm conditions) potentially affecting a presumptive test result. Humidity as well as direct sunlight causes degradation of the DNA.

3. **Substrate Material**: Blood can be deposited on non-absorbent surfaces which make the blood readily available for testing or on absorbent surfaces which pull the blood into its matrices, such as on fabric, wood and concrete. The absorbancy of these materials will have an affect on the method of collection and potentially the presumptive testing. Bloodstains that have been washed and/or bleached pose another problem to presumptive testing results and should be considered when conducting the test.

### ORTHO-TOLIDINE (O-TOL)

**Materials**

1. Ethanol, distilled water, 3% hydrogen peroxide, o-tolidine working solution, swabs or filter paper, blood standard

**Procedure**

1. Blank: Add one drop of ethanol (optional) to a clean swab or piece of filter paper. Add one drop of o-tolidine working solution and follow with one drop of 3% hydrogen peroxide. No immediate color formation should occur. If one does, repeat the test replacing just one of the solutions each time until no color forms. Discard the contaminated solution. A blank should be run prior to each testing session or when a solution has been replaced.

2. **Known Blood Standard**: Transfer a small portion of the known blood onto a piece of filter paper or swab (may be slightly moistened with distilled water, if needed). Add one drop of ethanol (optional) followed by a drop of o-tolidine working solution and a drop of 3% hydrogen peroxide onto the filter paper or swab. The immediate formation of a blue color should result. This should be done for each testing session to ensure the reagents are working properly.

3. **Test**: Transfer a small portion of the suspected bloodstain onto a piece of filter paper or onto a swab that has been slightly moistened with distilled water. Pipet one drop of ethanol (optional) onto the swab or filter paper, one drop of the o-tolidine working solution followed by one drop of 3% hydrogen peroxide. The immediate formation of a blue color indicates the presence of blood.

4. Repeat the procedure from a visually unstained area of the substrate, if possible.

5. **For older, less soluble stains**, test directly by removing a small portion of the stained (and unstained) substrate material and add one drop (or a smaller volume, as appropriate) of the o-tolidine working solution followed by the same volume of 3% hydrogen peroxide. The immediate formation of a blue color indicates the presence of blood.

**Interpretation**

1. The rapid appearance of a blue color, typically < 5 seconds, indicates the presence of blood.

2. A known bloodstain and reagent blank must be tested each session the o-tolidine reagents are used to demonstrate the reagents are working properly.

3. Catalytic blood tests are very sensitive, but not specific. The positive color test alone should not be interpreted as indisputable proof of the presence of blood.

4. The major sources of false positives are chemical oxidants and vegetable peroxidases.

5. A color reaction which occurs after the addition of the o-tolidine solution, but before the addition of 3% hydrogen peroxide, indicates a non-specific reaction caused by a chemical oxidant.

### HEMATRACE CHARACTERIZATION OF HUMAN HEMOGLOBIN

**Materials**

1. ABAcard HemaTrace test devices, extraction vials with elution buffer, sterile water, and human blood standard.

**Procedure**

If conducting: Direct Test Sample Method:
1. Fresh bloodstained materials are typically soluble, thus soaking the suspected bloodstain in 200 to 600 µl of the test kit buffer for at least 1 - 5 minutes should be sufficient. The volume of buffer is dependent on the concentration of the stain. Final extract should be light pink to straw color. Further diluting may be necessary for concentrated stains to avoid the "High Dose Hook" effect. Add 150 µl of the stain extract to the test kit cartridge, see procedure below.

2. Aged bloodstained materials or bloodstains that have been stored at room temperature for an extended period of time, may be insoluble, thus the suspected bloodstained material should be soaked in 200 to 600 µl of the test kit buffer for at least 30 minutes.

3. In some instances, an extended buffer soak alone may not be sufficient for a really insoluble stain. Soak the aged bloodstain in 100 to 150 µl of 5% ammonia for 5 minutes to an hour to extract the hemoglobin. The stain may also need to be incubated at 56 degrees. Allow the ammonia to evaporate. Add 150 µl of the test kit buffer. Add 150 µl of the stain extract to the test kit cartridge, see test protocol below.

If conducting: Recovery of Protein/Cellular Material an Integrated Method for DNA Analysis (See also BIO.1.BIO.09)

1. Add 50 µl of protein fraction extract (stain supernatant) to at least 100 µl of water or test kit buffer for a total volume of at least 150 µl. If the supernatant is still dark red, dilute further to avoid the "High Dose Hook" effect. Add 150 µl of the extract to the test kit cartridge.

2. Note: Since the cellular material associated with the tested protein fraction may ultimately be tested for human DNA, sterile technique is required throughout this testing method.

Test Protocol

1. Remove the test device from the sealed pouch and label each device with the name or item number of the sample being tested.

2. A known human blood sample (positive control) and a water or buffer blank (reagent negative control) should be run for each sample set to ensure the kit cartridges are working properly.

3. Add 150 µl of sample extract to the sample well 'S' of the test device. A fresh pipette tip should be used for each sample.

Read the result at 10 minutes. Positive results can be seen as early as 2 minutes depending on the human hemoglobin concentration. For negative results, wait the full 10 minutes.

Interpretation

In this test procedure the sample is added to the sample well 'S' and is allowed to soak into the strip. If human hemoglobin (hHb) is present in the sample, it will react with the mobile monoclonal anti-human Hb antibody and a mobile antigen antibody complex is formed. The mobile antibody-antigen complex migrates through the absorbent device towards the test area 'T'. In the test area 'T', the antibody-antigen antibody sandwich is formed. The conjugated pink dye particles concentrate in a narrow zone on the membrane. When the hHb concentration in the sample increases the excess 0.05 µg/ml, the pink dye particles will form a pink band in the test area 'T' indicating a positive result. As an internal positive control, hHb antibody-dye conjugates cannot bind to the antibody in the test area 'T', but are captured by an immobilized anti-immunoglobulin antibody present in the control area 'C' forming a complex. The captured pink dye particles will thus form a band in the control area 'C', indicating the test has worked properly.

1. Positive result:
   1. If there are two pink lines, one in both the test area 'T' and in the control area 'C', the test result is positive and indicates that the human hemoglobin level is at or above 0.05 µg/ml.
   2. Due to the extreme sensitivity of the test, traces of hemoglobin may be detected in body fluid samples other than blood (e.g. urine, semen, feces, saliva, vaginal fluid, and perspiration). Other cross reactions to non-human blood (e.g. ferret blood) have also been reported.

2. Negative result:
   1. If a pink line appears only in the control area 'C', the test result is negative. This may indicate that (a) No human hemoglobin is present above 0.05 µg/ml or (b) the presence of 'High Dose Hook Effect.'
   2. The 'High Dose Hook Effect' may give a false negative result in the presence of a high concentration of human hemoglobin in the sample. When a large amount of human Hb is present, some of the human Hb binds to the set of mobile antibodies and forms the antigen-antibody complex. Surplus unbound Hb migrates towards the test area 'T'. The fixed (immobilized) anti antibody in the test area 'T' is blocked by the surplus Hb. Therefore, the mobile antigen-antibody complex cannot bind with the fixed antibody located at the 'T' line to form the antibody-antigen-anti-antibody complex. As a result, no pink line forms in the test area 'T' irrespective of the large amount of Hb present in the sample, giving a false negative result.
   3. In such cases where the 'High Dose Hook Effect' is suspected, dilute the sample with the kit buffer to a lighter color and repeat. Generally, the bloodstain extract should be straw colored.

3. Inconclusive result:
   1. The control line in the control area 'C' is considered an internal control. The internal control assures that the proper test procedure was followed and indicates that the proper volume of sample was placed in the sample well and that capillary flow occurred. If there is no pink line visible in the control area 'C', the test is inconclusive. Repeat the test.
   2. Due to possible non-specific reactions that could occur, results should not be read after 10 minutes. Reactions that occur on or shortly after the 10 minute mark are considered inconclusive.
   3. The assay for human hemoglobin is sensitive enough to detect 'occult blood' in biological fluids such as semen and oral samples, therefore the lack of red coloration and a negative catalytic test in conjunction with a positive immuno-chromatographic test should be considered inconclusive for the presence of blood.

Safety

1. Safety precautions should be taken when working with blood (e.g. latex gloves, face mask, safety glasses). Eye and skin protection should be worn when working with acids and bases (NaOH).

2. O-tolidine is a possible carcinogen. Safety precautions should be taken when working with acids (e.g. latex gloves, face mask, safety glasses). Eye and skin protection should be worn when working with acids.

References

BLOODSTAIN PATTERN DOCUMENTATION AND OBSERVATIONS

Documentation of bloodstain patterns and subsequent interpretations will occur more often with crime scene personnel. Documenting the location and appearance of bloodstains and their patterns may be of significance; therefore, it is recommended that staff conducting biological examinations in the Biology Unit receive training in bloodstain and bloodstain pattern documentation. The biologist should be made aware of the theory behind the discipline, correct terminology, and its application in the interpretation of bloodstain patterns. An understanding
of the principles of bloodstain analysis can be helpful in recognizing stains of significance, methods of deposition, potential weapon-shapes as a result of transfer actions, and possible sequence of events.

Documentation

The primary role of the biologist in documenting bloodstains or bloodstain patterns is to properly document the appearance of stains. The location of the stain may have significance as well as the size, shape, distribution of multiple stains, target surface effects (e.g. saturation and texture), apparent voids, and apparent motion affects (e.g. feathering of transfer smears).

Stains should be documented through sketches and/or photographs and photographs should include appropriate reference scales and a means for associating the location of the stain on the evidence item. Multiple photographs may be needed to demonstrate pattern associations. For example, a garment with two apparent transfer patterns separated by a void can be recreated and documented by showing that a folding of the garment can create this transfer pattern. Other techniques can be used to visualize and document bloodstains and their patterns, such as infra-red photography and an Alternate Light Source (ALS), see BIO.1.BIO.2, Visual and Instrumental Examinations.

Interpretation

Interpretation of a bloodstain pattern varies from simple to complex. The forensic biologist needs to be aware of limitations to interpretation, especially since items submitted to the laboratory have been removed from the scene environment and may have been potentially altered upon removal from the scene or during storage. Actions at the scene and/or movement of the evidence prior to examination at the laboratory can alter the evidence, thus the analyst must consider these contextual affects which may limit an analyst's interpretation.

Interpretations may also be limited due to an analyst's training and experience. The analyst needs to be aware of their limits of interpretation. Interpretations and/or opinions offered need to be commensurate with the level of knowledge of the analyst, achieved through training and experience. Any conclusions offered will need to be adequately documented to evaluate the basis of the conclusion and reviewed by another analyst with equal or greater knowledge.

References

I. Semen Evidence

A. Semen is composed of liquid and solid components. The liquid portion is the seminal fluid and does not contain DNA, however DNA can be extracted from the epithelial cells mixed with the seminal fluid. The solid portion of semen consists of spermatozoa (also known as sperm cells) that contain the DNA. Typical male ejaculate contains two to six milliliters of semen with approximately 100 to 150 million sperm cells per milliliter. Because of this, semen is an excellent source of DNA. See BIO.2.DNA.02 for DNA analysis of samples containing semen.

B. Semen stains are typically not evident from a visual examination. Light sources, such as an Alternate Light Source (ALS), can assist in detecting semen stains. See BIO.1.BIO.02 for visual examinations using light sources. Once located, presumptive and confirmatory tests are used to test for the presence of semen.

C. Two components of semen, seminal acid phosphatase enzyme (AP) the prostate-specific antigen (p30), can be tested with presumptive tests. On an individual basis, both are considered presumptive tests for the presence of semen due to other biological substances that contain low levels of AP or p30. When detected in combination, it is a strong indication for the presence of semen. The most common confirmatory test for semen is the microscopic identification sperm cells (See BIO.1.BIO.02).

II. Acid Phosphatase Spot Test

A. The AP Spot test is typically used when examining a large surface area such as bedding or clothing and is not used during SAEK testing.

B. Materials

1. Spot wells or parafilm, disposable transfer pipette, falcon tube, SERI AP Spot Test PMR (part #R558a), sterile water, semen standard (dried whole semen stain)

2. SERI AP Spot Test Reagent: Add 0.26 grams AP Spot Test PMR to 10mL of sterile water, then mix until the AP spot test powder is dissolved.
   - The reagent is stable for one day's use.
   - Cover the tube with foil to protect the reagent from light.

C. Procedure

1. Blank:
   - Test the solution by adding one or two drops of SERI AP spot to a spot plate or parafilm.
   - No color reaction should be observed in the negative control.

2. Known Semen Standard: Test the solutions with a dried whole semen standard swatch.
   - Apply one or two drops of SERI AP to the semen standard in a spot well or on a piece of parafilm. A positive test is the rapid development of a purple coloration. Monitor for color change for no more than 1 minute.

3. Test: Remove a small cutting of the material to be tested (e.g., swab or fabric) and place in a spot well or parafilm.
   - Add one to two drops of SERI AP spot test to the spot well or parafilm. The solution should completely moisten the swab or fabric. Monitor for color change for no more than 1 minute.
4. If possible, test a substrate control (background material) by conducting the same procedure on an unstained portion of the fabric.

D. **Interpretation** Acid phosphatase is an enzyme present at elevated levels in seminal fluid, but also observed in vaginal secretions, feces, saliva, and other bodily fluids at lower levels.

1. **Negative results:** No color development or slow color development $>60$ seconds is considered a negative result. Color development may occur when testing vaginal secretions, therefore it is not recommended to perform the AP spot test on vaginal swabs.

2. **Positive results:** The rapid development of a purple/red coloration leaching into the solution, typically $<60$ seconds, is indicative of the presence of seminal fluid.

3. **Inconclusive results:** Development of color only on the fabric surface instead of color leaching into the solution is considered inconclusive for the presence of semen.

E. **Safety**

1. SERI AP Spot PMR is a possible carcinogen.

F. **References**

8. Dziack, Renata, "Providing Evidence Based Opinions on Time Since Intercourse (TSI) based on Body Fluid Testing."

III. **P30 Identification: ABACard p30 Test Strips**

A. **Materials**

1. ABACard p30 test devices
2. SERI semen standard (20 ng per aliquoted tube) or equivalent
3. Sterile water or ABACard Kit buffer

B. **Procedure**

1. Solubilize the evidence stain(s) in sterile water and create one to two reagent blanks corresponding to the evidence item. Follow "Protein/Cellular Material Recovery: An Integrated DNA Analysis Method", BIO.1.BIO.09, if additional screening tests or DNA testing are to be conducted on the suspected semen stain.

2. In separate tubes, add 50 µL of each solubilized protein extract to 150 µL kit buffer, making a 200 µL test solution. Note: the semen standard or evidence samples may be diluted further, if suspected to be too concentrated.

3. Positive Control: Obtain a 2 µL aliquot (10 ng/uL) of the Seri semen standard from freezer. Spin down the tube to remove any condensation on the cap. Add 375 µL of sterile water or buffer to the tube and mix to, create a $\sim0.05$ ng/uL of semen standard.

4. Remove the appropriate number of p30 test devices and droppers from sealed pouches. Label each of the test devices with identifying information.

5. Add 200 µL of test solution to the sample well 'S' of each labeled test device. This includes each of the evidence stains being tested, at least one associated reagent blank, and 200 µL of the prepared SERI standard. ($\sim10$ ng in 200 uL).

6. Read each result at 10 minutes. Positive results can be seen as early as 1 minute depending on the p30 concentration. Wait the full 10 minutes to interpret negative results. Have another biological screener verify the p30 results and add their initials and date to the notes or a photocopy or photograph may be taken and included in the notes.
7. A substrate control (stain control) can be run to verify that the reaction is due to the stain and not due to the substrate itself.

C. Interpretation

1. A sample is added to the sample well 'S' and allowed to soak into the membrane. If p30 is present in the sample, it reacts with the mobile monoclonal antihuman p30 antibody and a mobile antigen-antibody complex forms. This mobile antibody-antigen complex migrates through the absorbent device towards the test area 'T' and a polyclonal antihuman p30 antibody is immobilized. This immobilized antibody captures the above complex so that an antibody-antigen-antibody sandwich is formed. The conjugated pink dye particles concentrate in a narrow zone on the membrane. When the p30 concentration exceeds 4 ng/mL the pink dye particles will form a pink colored band in the test area 'T,' indicating a positive test result. As an internal positive control, p30 antibody-dye conjugates cannot bind to the antibody in the test area 'T.' They are captured by an immobilized anti-immunoglobulin antibody present in the control area 'C,' forming a complex. The captured pink dye particles form a band in the control area 'C,' indicating that the test worked properly.

2. Positive result: If there is a pink line in both the test "T" and control area "C", the test result is positive and indicates that the p30 level is at or above 4 ng/mL. The presence of p30 is a strong indication of the presence of semen, however other biological fluids (including vaginal fluid) have been reported to give positive results using this testing method. Results are not read after 10 minutes since non specific reactions may occur which could result in false positives.

3. Negative result: If there is only one pink line in the control area 'C,' the test result is negative. This may indicate no p30 is present or the presence of 'High Dose Hook Effect.'

4. The "High Dose Hook Effect" may give a false negative result due to the presence of a high concentration of p30 in the sample. Large amounts of human p30 bind to both the antibody to form an antigen-antibody complex , but also free p30 migrates towards the test area 'T'. The antibody in the test area 'T' is blocked by this free antigen. Therefore, the mobile antigen-antibody complex with the pink color cannot bind to the antibody. As a result, no pink line forms in the test area 'T,' giving a false negative result. In such cases where the "High Dose Hook Effect" is suspected, the sample may be re-tested using a 10 to 10,000 fold dilution.

5. The control line in the control area 'C' is considered an internal control. The internal control assures that the correct test procedure was followed, the proper volume of sample was placed in the sample well, and capillary flow occurred. If there is no pink line visible in the control area 'C,' repeat the test.

D. Safety

1. Latex gloves are to be worn at all times when handling semen evidence.

E. References

IV. Microscopic Examination of Spermatozoa

A. Materials:

1. Christmas tree stain (Serological Research Institute, R540)
2. Solution A (Kernechtrot Solution, nuclear fast red)
3. Solution B (Picroindigo carmine)
4. Ethanol and deionized water
5. Microscope slides and coverslips and mounting medium  
6. Microscope (Bright field, Phase Contrast)

**B. Procedure:**

1. Use a dry-mount slide prepared by a Sexual Assault Nurse Examiner, or prepare a cellular smear on a microscope slide using approximately 3 µl of cellular extract (see Sampling and Protein/Cellular Material Recovery, BIO.1.BIO.09)

2. If preparing from a cellular extract, dry the cellular smear and heat fix on a 56° C heat block.

3. Apply sufficient nuclear fast red (Solution A) to fully cover the cellular smear and allow to sit for 5 to 10 minutes.

4. Rinse Solution A from the slide with a gentle stream of deionized water. (Optional: dry the slide using a stream of warm air from a hair dryer.)

5. Apply sufficient picroindigo carmine (Solution B) to fully cover the cellular smear and allow to sit for up to 1 minute.

6. Rinse Solution B from the slide with a gentle stream of ethanol. Dry the slide.

7. Cover the cellular material with a coverslip with either Permount or Cytoseal fixative, minimizing bubbles.

8. Microscopically examine the stained smear using bright field (200 to 400X) and, optionally, using phase-contrast microscopy.

**C. Interpretation:**

1. **Differentially stained cells (Christmas tree Stain) - Bright field:** Nuclear material stains red, while cellular cytoplasm stains green to blue in color. Anucleated epithelial cells will stain primarily green in color, and will not have a red-stained nucleus. Nucleated epithelial cells will stain green to blue for the cytoplasm, and will have a red stained nucleus. Spermatozoa will have a red-stained body, with a lightly shaded acromere. The mid-piece and tail, if present, will be darkly stained.

2. **Differentially stained cells (Christmas tree Stain) - Phase Contrast:** Cells will have a three-dimensional "raised" appearance, and the nucleus of epithelial cells will stand out as a cell organelle. Spermatozoa will appear as a two-toned oval body, with the acromere appearing dark, while the base of the cell will appear bright.

I. Saliva Evidence

A. Saliva is a liquid that is secreted from the salivary glands in the human mouth. The source of DNA in saliva are the epithelial cells from inside the mouth that mixes with the saliva. Examples of evidence that would have saliva are, cigarettes, chewing gum, beverage containers, food, and bite marks.

B. Saliva is rich in salivary amylase (alpha-amylase) which is a digestive enzyme used to break-down starch. Amylase is found in other body fluids, such as blood, semen, vaginal secretions, perspiration, urine, and fecal material, but at much lower levels. It may also be detected in some non-human biological materials. Screening tests for saliva are therefore considered presumptive.

C. Saliva, like semen is typically not evident from a visual examination. Light sources, such as an Alternate Light Source (ALS) can assist in detecting a stain. See BIO.1.BIO.02 for visual examinations using light sources.

II. Amylase Diffusion Gel Procedure

A. Materials

1. 100 x 15 mm plastic petri dish
2. Heat source, such as a hot plate, microwave, or bunsen burner
3. Pasteur pipets
4. Aspirator
5. 37°C oven

B. Reagents

1. 0.1 M Phosphate buffer, pH 6.9
2. Agarose (e.g Sigma Type I)
3. Soluble starch
4. Lugol's 10X stock iodine solution
5. Saliva standard

C. Gel Preparation (1.0% Agarose/ 0.1% Soluble Starch) The following recipe is for one 100 x 15 mm plastic petri dish. Gel should be 2-3 mm thick. Adjust ingredients accordingly if a batch of plates are made.

1. To 20 ml of 0.1 M phosphate buffer, add 20 mg soluble starch and 200 mg agarose.
2. Heat the solution until boiling and thoroughly dissolve the agarose and starch.
3. Immediately pour the solution into a petri dish.
4. Cover the petri dish with a plastic lid to prevent inadvertent saliva contamination and let the gel solidify at room temperature.
5. Once the gel has solidified, punch holes in the gel using a pasteur pipet connected to an aspirator.
6. Leave at least 1.5 cm between the holes.
7. Label the holes (wells) with which sample will go into which well either on the bottom of the dish or on the lid cover.

D. Procedure:

1. Prepare a saliva standard dilution series (typically 1/10, 1/100, 1/200, 1/400, and 1/800.) Neat semen, blood serum, urine, or other physiological fluids may be used as a physiological reference as well.
2. Prepare question stain extract(s) according to the procedure in "Recovery of Protein/Cellular Material an Integrated Method for DNA Analysis," BIO.1.BIO.09.
3. Pipet 10 µl from each of the saliva standard dilutions, the questioned stain extracts, and reagent blank (negative control) into its labeled well. Use a new disposable pipet tip for each sample. Be careful not to overfill the wells. Keep the plate level and be careful not to upset the extracts in the wells.
4. Cover the petri dish and place into a zip locked plastic bag or other type of moisture chamber.
5. Allow the samples to diffuse by placing the gel into a 37°C oven and incubating overnight.
6. After an overnight incubation, the gel is stained with a 1/100 dilution of stock iodine solution in water. Flood the gel with the solution until the starch gel is stained a dark blue. Iodine solution should completely cover the gel surface. Clear (unstained) circles around a sample well indicates amylase activity. The amount of amylase activity in a sample is logarithmically related to the diameter of the clear ring surrounding the well.

7. Measure the diameter of the rings to the nearest millimeter and photograph on a light box. Photograph with a scale.

E. Interpretation

1. Amylase hydrolyzes starch, first to oligosaccharides, then to maltose and glucose. As a sample containing amylase diffuses into the gel from the well, starch is hydrolyzed in an area proportional to the concentration of amylase present in the sample. Iodine reacts with unhydrolyzed starch to produce a deep blue color which can be differentiated from the clear circles where amylase has hydrolyzed the starch.

2. Amylase is present in saliva at high concentrations, hence its use as a presumptive test for saliva. However, amylase is present in most body fluids and tissues including semen, vaginal fluid and urine though generally at much lower levels than found in saliva. Perspiration, breast milk and feces may have high levels of amylase. Neat vaginal swabs have been reported with amylase levels up to the equivalent of a 1/100 dilution of saliva.

3. The ring diameters of the unknown samples are compared to the ring diameters of the saliva standards to give a semi-quantitative measure of the level of amylase present in the unknown samples.
   a. In general, a high level of amylase (greater than the 1/100 standard) is considered significant and is indicative of saliva.
   b. In general, a moderate level of amylase (generally between the 1/100 and 1/800 standards) suggests the possible presence of saliva. Moderate levels of amylase can be observed in saliva, as well as, in other physiological fluids, therefore, amylase detected at this level is inconclusive for the presence of saliva.
   c. In general, a very low level of amylase (generally below the 1/800 standard) to no clearing indicates that saliva was not detected based on the absence of amylase activity.

4. These interpretive guidelines are subject to many variables such as, potential concentration effects, endogenously high levels of amylase in other physiological fluids of certain individuals, or the expected endogenous levels of amylase on various substrates or items. The interpretive statement should take into account these possibilities.

5. The amylase diffusion test may be coupled with a microscopic examination for buccal epithelial cells in determining the possible presence of saliva. Buccal epithelial cells are a rich source DNA for genetic marker typing.

III. Amylase Mapping

A. Materials

1. 37° Oven
2. Heat source, such as a hot plate, microwave, or bunsen burner
3. 11 cm x 20.5 cm Gel Bond or glass plate of equal size
4. Staining tray

B. Reagents

1. 0.1 M Phosphate buffer, pH 6.9
2. Agarose (e.g Sigma Type I)
3. Soluble starch
4. Lugol's 10X stock iodine solution
5. Saliva standard

C. Gel Preparation (1.0% Agarose/ 0.1% Soluble Starch)

1. Prepare 40 milliliters per 11 cm x 20.5 cm piece of Gel Bond or a glass plate of equivalent size.
2. Add 40mg soluble starch and 400 mg agarose (e.g. Sigma Type I) to 40 ml of 0.1M phosphate buffer.
3. Heat the solution until boiling to dissolve the agarose and starch.
4. Cool the mixture to approximately 70° C, then pour the solution onto the Gel Bond or glass plate.
5. Allow the gel to solidify at room temperature in a covered container or in a protected area.

D. Mapping:

1. Place the Gel Bond or glass plate on top of the suspected saliva stained area with the gel face down.
2. Place a positive control on the gel in a location away from the tested area.
3. Make orientation marks on the plate and garment.
4. Let gel sit on top of the garment for 15 to 30 minutes with light weight applied to the plate.
5. Place the plate in a moisture chamber and incubate in a 37° oven for 30 to 60 minutes.

E. Staining:
1. Stain the gel by placing the plate in a staining tray and flooding the plate with a sufficient volume of a 1/100 dilution of stock iodine solution to stain the starch gel dark blue. An area of clearing (unstained area) indicates the presence of amylase.

F. Sampling:

1. Re-orient the stained gel over the evidence, which was mapped, and mark the evidence in the area which corresponds to the clearing on the gel. Take samples from the item near the center of the outlined area.

G. Interpretation:

1. Amylase hydrolyzes starch, first to oligosaccharides, then to maltose and glucose. As a sample containing amylase diffuses into the gel, starch is hydrolyzed in the area. Iodine reacts with unhydrolyzed starch to produce a deep blue color which can be differentiated from an area of clearing in the gel where amylase has hydrolyzed the starch.

2. Amylase is present in saliva at high concentrations, hence its use as a presumptive test for saliva. However, amylase is present in most body fluids and tissues including semen, vaginal fluid and urine though generally at much lower levels than found in saliva. Perspiration, breast milk and feces may have high levels of amylase. Neat vaginal swabs have been reported with amylase levels up to the equivalent of a 1/100 dilution of saliva.

3. The mapping technique is used only as a screening tool and gives no information about the relative level of amylase which may be present. The mapping technique should be followed by the amylase diffusion test which is a semi-quantitative assay.

IV. RSID Saliva Cards

A. Materials

1. RSID Test Cassette
2. RSID Saliva Running Buffer
3. 1:10 Saliva Standard
4. pipettes and tips

B. Procedure

1. Prepare questioned stain protein fraction extract(s) according to the procedure in "Recovery of Protein/Cellular Material an Integrated Method for DNA Analysis," BIO.1.BIO.09.
2. Combine 20uL of the solublized protein extract with 80 uL of RSID Saliva Running Buffer to bring the sample up to a total volume of 100uL.
3. Prepare a positive control using 20uL of the 1:10 saliva standard and 80uL of RSID Saliva Running Buffer.
4. Prepare a negative control using 20uL of a reagent blank and 80uL of RSID Saliva Running Buffer.
5. Remove the appropriate number of RSID test devices from the sealed pouches. Label each of the test devices with identifying information.
6. Add 100uL of the test sample in running buffer to the sample window.
7. At 10 minutes, score, and record results.
8. Results should be evaluated as follows:

   (1) Negative Result – A visible red line at the Control (C) line indicates a negative result, showing that α-amylase has not been detected.
   (2) Positive Result - Two visible red lines at the Control (C) and Test (T) lines indicate a positive result, showing that the α-amylase has been detected.
   (3) Test Failure Result – No visible red line at the Control (C) line indicates a failed test.

C. Interpretation

1. The RSID lateral flow immunochromatographic strip test uses two mouse monoclonal antibodies specific for human salivary α-amylase. One antibody is conjugated to colloidal gold and is placed on a conjugate pad beneath the sample window, while the other antibody lines the “Test line” on a membrane attached to the conjugate pad. The “Control line” on the membrane is made up of anti-mouse IgG antibody and is used as the control for this test. A red line should form at the control position of each strip to show that the sample fluid traveled the length of the test, in addition to showing that the test components of the strip test functioned correctly. Attached to the other end of the membrane is the wick, which absorbs the tested fluid and running buffer at the completion of the test, preventing back-flow of the sample. When the test fluid is added to the sample window, the sample and running buffer diffuse through the conjugate pad, re-dissolving the gold-conjugated detection antibodies.

2. Positive result: If human salivary amylase is present in the sample an antigen-colloidal gold conjugated antibody complex will form. Sample and antibodies (complexed and free) are transported by bulk fluid flow to the membrane section of the strip test. The immobilized anti-α-amylase antibodies on the test line capture the amylase-antibody-gold complexes, producing a red line at the Test position.

3. The presence of human salivary α-amylase is a strong indication of the presence of saliva, however other biological fluids (including breast milk, feces, and vaginal fluid) have been reported to give positive results using this testing method. Results should not be read after 10 minutes since non specific reactions may occur which could result in false positives.

4. Negative result: If there is only one red line, in the control area the test result is negative. This may indicate that (a) No salivary amylase is present above the limit of detection (<1uL) or (b) the presence of 'High Dose Hook Effect.'
5. The "High Dose Hook Effect" may give a false negative result due to the presence of a high concentration of salivary amylase in the sample. Large amounts of human salivary α-amylase bind both to the antibody to form an antigen-antibody complex but also free human salivary α-amylase migrates towards the test area 'T'. The antibody in the test area 'T' is blocked by this free antigen. Therefore the mobile antigen-antibody complex with the red color cannot bind to the antibody. As a result no red line will form in the test area 'T' although there is a large amount of human salivary α-amylase present in the sample giving a false negative result. In such cases where the "High Dose Hook Effect" is suspected, the sample may be re-tested using a 10 to 10,000 fold dilution.

6. **Test Failure Result:** If there is no red line visible in the control area 'C', the test is inconclusive. Repeat the test. The control line in the control area 'C' is considered an internal control. The internal control assures that the correct test procedure was followed and indicates that the proper volume of sample was placed in the sample well and that capillary flow occurred.

V. **References**

I. Biological Collection Guidelines

A. Swabs: The amount of biological material to sample is dependent on the amount of original evidence material. In general, when working with swabs, 1/2 of a swab is sampled for protein and cellular characterizations. If sufficient cellular material is estimated to be present, the sample may continue forward for DNA analysis. If the analyst determines that a 1/2 swab does not offer sufficient biological material for testing, the entire swab may be sampled.

B. Stains: Biological stains can be deposited on a variety of substrates that may be absorbant or non-absorbant surfaces. In general, biological stains deposited on absorbant surfaces can be directly cut out or swabbed and stains deposited on non-absorbant surfaces can be collected onto swabs. Blood deposited on non-absorbant surfaces can also be directly collected from the surface by carefully collecting flakes or crusts of the biological material. The best collection method is determined by the quantity and quality of the biological sample, as well as, potential quality issues with the substrate that the biological material is deposited on. In general, when collecting a biological stain a cutting approximating 0.5cm x 0.5cm is collected. If the analyst determines that a 0.5cm x 0.5cm cutting does not offer sufficient biological material for testing, then a 1cm x 1cm cutting may be sampled.

C. Substrate Controls: To monitor for potential background biological material, a sample of the background material or a swab of the substrate surface from an apparent unstained area may also be prepared to monitor for background proteins and cellular material. In instances where it is anticipated that the background will influence interpretation of the stain (e.g. when the stain is of limited quantity or concentration), it is highly recommended that an equal sized substrate control be sampled and run along with the stain sample.

D. Reagent Blanks (RB): For every sample set, one or more reagent blanks are required to monitor for potential contamination of the reagents used throughout the examination process. The reagent blanks must be treated in the same fashion as the evidence sample(s) and taken through every step as the evidence sample(s). Typically two RB(s) are set up with the set of evidence samples during the biological screening and examination process. The reagent blank(s) are retained with the sample set for potential future DNA testing.

II. Recovery of Proteins and Cellular Material

A. This method allows for simultaneous protein assays, microscopic examination of the cellular content, as well as, DNA analysis from the same sampled stain or swab of a stain. The process incorporates a methodical approach to separating the protein fraction from the cellular fraction of a biological sample that is intended for both presumptive tests and microscopic analyses. It also incorporates appropriate controls for subsequent DNA analysis.

B. Procedure

1. Cut an approximate 0.5cm X 0.5cm portion of the stain (or several small cut pieces of the stain), or 1/2 of a swab and place into a 1.5 mL or 2.0 mL microcentrifuge tube. Add approximately 300 µL of sterile water or PBS to the tube. If a whole swab or 1cm x 1cm cutting was sampled, add approximately 600 µL of sterile water or PBS to the tube. Ensure the stain material is thoroughly saturated. There may be samples in which these volumes need to be altered to accommodate larger sized samples.

2. Let the sample soak for 30 minutes to 1 hour at 4°C.

3. To recover the solublized protein fraction: Transfer the saturated substrate to a spin basket using a clean toothpick and place the spin basket back into the microcentrifuge tube. Centrifuge for 2-3 minutes at a high speed. Carefully pipette, the supernatent to another labeled 0.5ml tube. This is the protein fraction. Leave any cell pellet and ~50µL of supernatent at the bottom of the centrifuge tube.

4. The solublized protein fractions are not stable for extended periods of time, therefore protein testing should be conducted as soon as practicable to prevent denaturation of the proteins. The solublized protein fraction can be tested for proteins such as:
   - Human Hemoglobin: see BIO.1.BIO.03
   - P30: see BIO.1.BIO.04
5. **To recover the cell fraction**: Remove the stain substrate from the spin basket and place the substrate back into the centrifuge tube containing the 50µL cell pellet. Add 500 to 600 µL of sterile water and again thoroughly saturate the stain substrate. Repeatedly, as needed, agitate the substrate with a clean toothpick and vortex to remove cellular material from the substrate. If this is done at the end of the work day, the substrate may be soaked for several hours to overnight at 4°C, if needed, prior to agitation.

6. After agitation, return the substrate back into the spin basket and centrifuge 2-3 minutes at a high speed.

7. After centrifugation, remove and discard all except for ~50µl of the supernatant being careful not to disturb the cell pellet at the bottom of the tube.

8. Re-suspend the cell pellet in the 50µl of liquid by gently vortexing.

9. Remove 3µl and place onto a microscope slide and heat dry the slide.

10. Microscopically examine the dried deposit to assess the cellular content using a microscope at 200X to 400X. See [BIO.1.BIO.02](#) for microscopy methods and cytological staining procedures.

11. If the presence of spermatozoa and/or epithelial cells is deemed significant, estimate the quantity of cellular material in the 3µl. In general, the estimate is used to assess whether there is sufficient cellular material to continue with DNA analysis.

12. If the stained sample is deemed probative, the remaining protein fractions, cell pellet fractions, and substrates should be retained particularly if the original biological stain is limited or additional testing, such as DNA analysis will be continued from the generated samples. If any additional testing or further analysis cannot be done immediately, the fractions and substrates should be stored frozen. If the samples will continue on for DNA digestion of the cellular material, see [BIO.2.DNA.02](#) for the method and procedure.

13. If the stained sample is deemed non-probative, or ample stain material remains for additional testing and the generated protein/cell pellets/substrates will not be used for further testing, they may be discarded as work product.

14. The disposition of all samples should be reflected in the case record, generally in the analyst case notes.

---

**END OF DOCUMENT**
Preparation of Reference Blood Standards

For purposes of preservation, the Biology Unit creates dried reference blood standards from liquid blood that has been drawn from individuals involved in a criminal case. The dried reference blood standards are maintained frozen in the Laboratory, or for older cases, maintained frozen at Sheriff's Property.

The dried reference blood samples may be used as DNA reference samples for DNA typing, should an investigative need arise. When a reference blood sample is examined as part of a case and while in the custody of the Laboratory, the reference blood is treated as evidence and will follow evidence handling requirements outlined in FSD.35, FSD.36, FSD.38 and FSD.39 (ISO/IEC: 17025 5.8.4.6).

Access to the reference samples is provided to the Biology Unit staff for dried blood preparation assignments and/or for casework assignments. When a sample is used in casework or a need arises to split a portion of the sample for another laboratory, it will be documented in the examination records.

### Equipment/Materials

- 20% Bleach
- Evidence Tape
- Butcher Paper
- Coin Envelope
- Cotton Swatches (5 x 5 cm)
- Computer Generated Labels
- Weigh Boats
- Tube Protectors
- Disposable Pipettes
- Vacutainer Opener (optional)
- Test Tube Rack (optional)

### Safety

- Personal Safety Equipment:
  - Latex Gloves
  - Goggles
  - Lab Coat
  - Dust Mask

  (Optional: A full face shield in lieu of goggles and mask).

  Note: Universal Safety Precautions against infectious materials must be followed throughout.

### Prepare JusticeTrax:

1. Liquid Blood Evidence Kits are typically stored in the evidence log-in refrigerator. A photocopy of the Liquid Blood Evidence Kit serves as the Laboratory's request for service. A LIMS Assignment Notification form accompanies the request when the request has been assigned. Retrieve the Liquid Blood Kit(s) from the log-in refrigerator (if applicable) and transfer the kit into your custody by conducting an electronic transfer in JusticeTrax.

2. Verify in JusticeTrax that the request is assigned to the correct analyst. Correct (if needed) by editing the request. (Note: an analyst must be assigned to create a worklist in JusticeTrax. See "Create a Worklist in JusticeTrax" below)

3. Verify in JusticeTrax that the source of the blood is correctly listed in the "Source" window. Correct (if needed) by editing under the evidence tab: Select the "Edit" button beneath the Submissions List pane. Select the correct individual from the pull-down menu in the "Source" window. Re-select the "View" button to prevent further edits to the submission.

### Create a worklist in JusticeTrax:

1. Select Analysis > Create Worklist
2. Select Forensic Biology as the Unit
3. Select the Liquid Blood request as the Service
4. Select Name of Analyst from Analyst pull-down.
5. Click "OK"

   A "Create Worklist" window opens. Using a barcode reader, scan the Barcode of each liquid blood request from the Assignment Notification form.

7. Click "Create Worklist" button. A worklist listing each associated request will appear.

8. Print the worklist (the barcode of the worklist will serve to associate all requests for all stages of the work and review process.)

### Prepare evidence labels in JusticeTrax:

1. Select Administration > Crystal reports>Generate Reports
2. Select Report Category DNA
3. Select DNA Worklist Labels and click "Print" and choose "Screen."
4. Complete the prompts:
   1. Initials and Date (e.g. 6-18-09 DCS)
   2. # of rows to skip ("0" for a new page, or the appropriate number to skip lines of labels.)
   3. Worklist barcode (Scan the worklist barcode(s).)
5. Print the worklist labels sheet on Avery 5267 labels.

### Prepare coin envelopes for dried reference blood swatch(s):
1. Place one of the worklist labels on the top front of a coin envelope. Verify the label has the following information: Lab Number, Submission #, Name of Individual's blood, Agency and Agency Case Number.
2. Add the appropriate sub-item number to the coin envelope.
3. Initial and date the label.
4. Place a pre-printed barcode label on the bottom of the envelope for registration in JusticeTrax (see Itemization procedure below).

**Itemize in JusticeTrax each new dried reference blood swatch(s).**

1. Right-click on the Liquid Blood request, select "Edit Findings"
2. Right-click on the Submission Number, select "Itemize Evidence"
3. In the "Description" field in the New Evidence Submission window, enter the description of the new dried reference sample: "Envelope: dried reference whole blood from [Name of Source]."
4. Change "Bar Code" Field to "0"
5. Verify that the "Inherit" field reflects the proper submission number and description of the Liquid Blood Evidence Kit.
6. In the "From" field, select the analyst's barcode and enter PIN for a secure transfer. Do this even if the "From" field is already populated with the Analyst, otherwise it will not be a secure transfer.
7. In the adjacent "Via" pull-down menu, select "Split Chain of Custody."
8. In the "TO" field, select "Escobar Freezer-Evidence Room 3". A pop-up message will say the container (original liquid blood submission) will not be changed. Click "OK". This will split the dried reference blood swatch and chain of custody from the liquid blood submission.

*Note: If the procedure will be started but completed the next day (i.e. the blood needs time to dry overnight), transfer the dried blood swatch to the Analyst Workspace instead of to the "Escobar Freezer-Evidence Room 3". The next day, transfer the dried reference blood "From" the analyst's workspace "TO" the analyst, "Then TO" the Escobar Freezer-Evidence Room 3.

9. Click on the Barcode icon button, select "Register". Scan the pre-printed barcode(s) label on the coin envelope(s).
10. Click "Apply"

**Procedure**

1. Wipe work counter with 20% bleach and then cover with butcher paper.
2. Perform steps 2-10 to completion before moving onto the next step to reduce the risk of sample mix-up. Select a Liquid Blood Evidence Kit. Verify that the information on the envelope matches the information on the Assignment Notification form. (If wrong on the Assignment Notification then its wrong in JusticeTrax and needs to be corrected).
3. Open the envelope. Do not cut over existing evidence tape, if possible.
4. Place one of the four generated labels (see above) onto the blood tube and one onto a cotton swatch cloth. Initial the labels. Place the swatch into a plastic weigh boat. Cross check all identifying information to ensure that the proper blood sample label is placed on the appropriate blood swatch cloth.
5. Open the vacutainer either with a vacutainer opener or by hand. If using a vacutainer opener, be sure to clean the inside with 20% bleach before using.
6. Using a disposable pipet, deposit 3-4 drops of blood onto the swatch. This should cover at least half of the swatch. Close the blood tube and dispose of the pipet in a biohazard container.
7. Using the LIMS Assignment Notification sheet as a note page, record the condition in which the evidence was received (i.e. tape sealed, dated and/or initialed seal), what type of vacutainer was present (i.e. purple top, gray top, ect), and identifying blood donor information on the tube. Record the transfer of the liquid blood sample onto the swatch. Record the disposition of the liquid blood and dried blood swatch.
8. Set the weigh boat and blood swatch aside to dry.
9. Close the blood tube and place back into its protective sleeve. Place the assembly back into the Liquid Blood Evidence Envelope. Seal envelope with evidence tape.
10. When the blood swatch is dry, remove the sample from the weigh boat and place with attached label into the prepared coin envelope (see above) using tweezers. Be sure to wipe the tweezers with 20% bleach and then again with deionized water before moving on to the next sample.
11. Seal the coin envelope with evidence tape. Initial and date the seal.
12. Dispose of the weigh boats and butcher paper in a biohazard container and wipe the work area with 20% bleach.
13. Place coin envelopes into the Laboratory freezer.
14. Return the Liquid Blood Evidence Kit to submitting agency.

**Reporting:**

1. Prior to generating a report in JusticeTrax, open the Lab number and verify that all evidence is in the correct location.
2. A "Record of Notification Report" limited to the following sections; Evidence Receipt date and Evidence Description List, Purpose, and Disposition of the liquid blood and dried blood samples will be written.
3. An example "Purpose" statement is:

   "To preserve a reference blood sample from [name of blood donor], a portion of the liquid blood contained within the Liquid Blood Evidence Kit was transferred to create a dried blood sample. The dried blood sample may be used as a DNA reference for [name of donor] should an investigative need arise.

   An example “Disposition” statement is:

   “The dried blood sample will be maintained in the Laboratory’s reference blood collection. The Liquid Blood Evidence Kit will be returned to the agency.”

Alternatively, if the liquid blood is from a Blood Alcohol/Drug Kit, change report verbiage to reflect the liquid blood is from a Blood Alcohol/Drug Kit. Additionally, indicate in the disposition that the kit will be dispositioned to the Drug, Alcohol, and Toxicology section of the laboratory.

Verify the information contained in the report is accurate and turn in for an administrative review.

**Dried Reference Sample Splits**

1. When it is necessary to split a dried reference sample, the request is documented in the case record. Prior to splitting the sample, verify there is sufficient sample before preparing a sub-sample. The split is documented in JusticeTrax, see QA.09 Division Itemization Procedure for guidance. For samples to be mailed or couriered see FSD.35 for guidance.

</table>
The laboratory provides several kits for the collection of evidence and reference standards. The following is the list of kits provided and used by the laboratory with a short description detailing the access and release of the kits to outside agencies.

### DNA Reference: Blood Evidence Kit (RBEKs)

RBEKs are provided to the Coroner’s office to be used specifically for the collection of DNA reference samples from deceased individuals whose death is related to a criminal investigation.

Instructions on how to collect the blood sample is included with the kit.

The law enforcement agency associated with the criminal case is responsible for obtaining the kit from the laboratory when a DNA sample from the deceased is needed.

### Liquid Blood Evidence Kit

Liquid blood Evidence kits are no longer provided to outside agencies for the collection of known reference blood samples.

The liquid blood kit has been replaced by the “Reference Blood Evidence Kit” for deceased individuals or the “DNA Reference/Oral Swab Kit” for living individuals.

### Oral Swab DNA Reference Kit

Oral swab kits (also known as Buccal swab kits) are provided to law enforcement agencies upon request and are used to collect DNA reference samples from living individuals, such as victims, suspects, or third party persons for elimination purposes.

Instructions on how to collect the oral swab is included with the kit.

This kit should not be used to collect biological evidence at crime scenes and is not intended to be used in place of the CA Department of Justice DNA databank sample.

### Fingernail Evidence Kit

The Laboratory provides fingernail evidence collection kits to the Coroner’s office specifically for the collection of physical and biological evidence on deceased individual associated with criminal cases.

Fingernail and toenail clippings may be collected for potential foreign DNA, trace evidence, or may be collected as a DNA reference standard for the deceased individual when the body is in a severe state of decomposition.

When the individual’s nails are insufficient for clipping, the fingertips and/or hands may be swabbed instead, when applicable. Swabs are not included in the kit.

### Sexual Assault Evidence Kit

Sexual assault kits are provided for the purpose of collecting biological evidence associated with the body of a sexual assault victim. These kits are supplied only to the Sexual Assault Regional Training (SART) Coordinator or representative.

The laboratory provides paper bags to the SART Coordinator or representative for the collection of clothing. The paper bags are prepared in-house with adhesive labels that are custom-ordered. The labels are ordered from graphics@pw.cccounty.us.

A Sexual Assault Kit may be provided to the Coroner’s office to be used on the deceased, in cases where sexual assault is suspected. However, this should only be done when Autopsy Sexual Assault Kits are unavailable.

The law enforcement agency associated with the criminal case is responsible for taking custody of the kit from the hospital and preserving the kit until submitted to the laboratory for examination.

The Sexual Assault Evidence Kit is custom ordered from TRITECH FORENSICS and arrives pre-assembled. Each kit contains the required components, as specified by the Laboratory.

The kits are to be stored at room temperature before use and should be stored frozen after use.

### Dodd Romano & Debbie McKillop

APPROVED BY: Kim Willey, Dawn Romano & Debbie McKeith

CHAPTER: Biology Technical Unit Manual

REVISION DATE: 05/19/17

NUMBER: BIO.1.BIO.12 - Evidence and Known Reference Standard Collection Kits

RELATED ORDERS:

ASCLD-LAB:

SUBJECT: Evidence and Known Reference Standard Collection Kits
FTA cards are provided to the SART at the Contra Costa Regional Medical Center in conjunction with the Sexual Assault Kits but separately. These are used in place of an oral reference sample when an oral swab cannot be collected.

**Autopsy Sexual Assault Kit**
The sexual assault kits used during an autopsy are prepared in-house. The kit contains the following components or equivalent:

1. Pubic combing/brush (TRITECH FORENSICS)
2. Pubic lifter (TRITECH FORENSICS)
3. Small envelopes each containing 1 slide & slide holder for oral, rectal, and vaginal smears, with labels
4. Envelopes: 1-vaginal w/ 4 swabs; 1-rectal w/ two swabs; 1-oral with 2 swabs
5. Labels (Avery 5960 & 5267 & 5162). Label templates under Serology/Kits/Autopsy SAEK labels
6. Evidence tape
7. Chain of custody label

**Suspect Sexual Assault Evidence Kit**

Suspect sexual assault kits are provided to the Sheriff's Office jail, and to other law enforcement agencies, upon request. The kits are to be used to aid in the recovery of physical evidence from the body of a sexual assault suspect. The kit should be used to collect potential evidence within 24 hours of the offense or when there is information that evidence may still be on the suspect past the 24 hour time frame.

For digital penetration cases, 1 or 2 swabs should be used to swab the fingers from each hand. Place the samples from each hand in a separate, labeled envelope. **Do not** collect a separate swabbing from each finger.

If a male suspect has been taken into custody within 24 hours of the incident and/or has not showered or bathed, a penile swab should be collected. The suspect’s underwear should also be collected and may provide a source of the victim’s DNA.

Instructions on the collection of the samples are included in the kit.

The law enforcement agency associated with the criminal case is responsible for taking custody of the kit.

This kit is custom ordered by the laboratory from TRITECH FORENSICS and comes to the laboratory pre-assembled.

The kits are stored at room temperature prior to use and should be stored frozen after use.

END OF DOCUMENT
Introduction
Hairs and fibers can be significant in making associations between persons and/or a crime scene. On a case by case basis, the potential significance of any trace evidence should be considered by the examiner. Case circumstances and/or the nature of the case may guide the examiner in determining the value or need for the collection of any trace material.

Role and Goal
The role of any examiner in the Biology Unit is to recognize and collect trace evidence of potential value. It is not the examiner's role to identify the trace material. However, the examiner should be able to make general observations and document those observations for the purpose of distinguishing hairs from fibers, when possible. Basic training on gross characteristics, such as color, length, and morphology of hairs and fibers will be provided to the examiner. The examiner will be trained to use the stereomicroscope and compound microscope to assist in determining general and/or specific characteristics about the trace material. If the trace evidence is determined to possess associative value, the trace material will be preserved for a qualified trace examiner, if required.

When the trace material has been determined to be a hair, the role of the examiner is to make general observations and document the observations for purposes of distinguishing the hair as likely originating from an animal or human, where possible. Human head hair and pubic hairs, where the root is intact, generally will possess enough microscopic features to evaluate whether the hair is likely human and whether it is adequate for DNA analysis. The main goal of the examiner in the Biology Unit is to determine if the hair is amenable for nuclear DNA typing. Human hairs from body parts other than the head and pubic area, where the root may or may not be present, are typically not well suited for DNA analysis.

DNA Suitability
Hair is a filament growth from the skin. Hair grows from a follicle embedded in the skin and consists of the shaft and the root. The hair shaft extends out of the skin with the root embedded in skin. Hair grows in three stages; anagen, catagen, and telogen. Anagen is the active growing phase, catagen is the intermediate phase when hair has stopped growing, and telogen is the resting phase when hair is naturally shed. At any stage of hair growth, the hair has the potential to have cellular material/tissue from the follicle attached to the root, however anagen hairs have a higher chance of possessing cellular material because the hair is still actively growing and mostly still embedded in the hair follicle.

Hairs Suitable for Nuclear DNA Analysis:

Because nuclear DNA is degraded during the hair's keratinization process, the nuclear DNA material is typically found only in the root material of anagen and catagen hairs, specifically in the sheath material and in the bulb cells. These hairs can often be identified by an evenly pigmented bulb. DNA may also be found in telogen hairs with follicular tags. This is viewed as a clump of cellular material attached to the root and most often observed with coarse hairs such as pubic and beard hairs.

1. Anagen: The growing phase of a hair where the pigment (color) is typically continuous to the root. There can be a thin clear/transparent root sheath at the root end which is a rich source of nuclear DNA. The presence of the sheath can indicate the hair was forcibly removed. Forcibly removed does not equate to a struggle. Other facts of the case may support how the hair was removed.
   The shape of the hair root is typically bulbous and under polarized light, the cuticle is bright (due to keratin) but the root area is dark due to lack of keratinization.

2. Catagen: An intermediate/transitional phase where the pigment is reduced above the root bulb and there is a reduction in the root sheath. There may be a follicular tag adhering to the root and the root is more club shaped.

3. ***Telogen: A resting phase where there in no root sheath, possibly no medulla, and no pigmentation above the root bulb. The root bulb is hardened, club shaped, and the root area is birefringent under polarized light. The root can have follicular tags, more common from coarse hair regions, such as pubic and facial hair. Note: telogen does not always mean shed. A shed hair can be forced out and may be accompanied by a translucent germinal nipple. The germinal nipple is typically not suitable for nuclear DNA testing however the hair is suitable for mtDNA testing.
Microscopic view of two hair roots. The hair at left has a layer of translucent tissue surrounding the root, indicating it was forcibly removed from the person’s head. The hair root at the right does not have this tissue layer, indicating it probably shed naturally from the head. The root with tissue on it is more likely to yield DNA results than the other one.

**Hairs Suitable for mtDNA Analysis:**

1. Hairs that do not possess detectable amounts of nuclear DNA (telogen hairs and fragments). The mitochondrial DNA is contained in the shaft and in the telogen bulb.

2. The path traveled by the mitochondrial cell originates in the bulb and ultimately ends in the keratinized hair shaft. There are multiple copies of the mtDNA in each mitochondrion and hundreds of mitochondria in each cell = thousands of copies of mtDNA. Note: the inheritance of mitochondrial DNA is strictly maternal.

**Examination**

**Materials**
- Microscope slides
- Coverslips
- Forceps
- Trace collecting materials: Post-its, glassine paper, tape lifts or other collection device
- Water or mounting medium
- Microscope (Bright Field, Polarizing) and Stereomicroscope (transmitted and reflected)

**Procedure**

1. The trace evidence may be collected by either individually picking the material off or by using an adhesive tape lift method. In circumstances where the removal of the trace material could lead to damage or loss of the material, the material may be left in place. If using the pick method, use forceps and be careful not to pinch, crush or stretch the hair when retrieving it. If using the tape method (fingerprint tape, cellophane or clear adhesive), pat over the item. Take care not to miss any areas or overload the tape. Post-it type notes can also be used for small areas or for holding the trace material that has been picked off.

2. Examine the trace material under a stereomicroscope under transmitted and reflected light. Hairs and fibers may be mounted to a microscope slide or to the sticky side of a tape lift. Place the strand underneath the scope and adjust the magnification and focus. Document your observations: color of hair/fiber under both types of light (transmitted and reflected). The color can appear different under each light.

3. To differentiate between a hair and a fiber, it may be necessary to also view the unknown strand under a microscope (Bright Field and or Polarized). Place the strand on a microscope slide, add a drop of water, and cover with a cover slip. To determine if the strand is a hair, look for hair characteristics (discussed below) and document your observations. Note: the various components of hair have different refractive indexes, thus the ability to observe hair characteristics such as scale pattern and medulla will be affected by the mounting medium.

4. To determine if the hair is suitable for nuclear DNA testing, examine the root end of the hair, if present. Look for any clear/transparent sheath material adhering, or any follicular tag or other cellular material adhering to the root end. Hairs with germinal nipples typically do not possess sufficient nuclear DNA.

5. Observe the hair shaft for adhering biological material, such as blood, semen or other trace material. The adhering material may be collected if it has evidentiary value or discarded. The adhering material on the shaft can be swabbed off or the hair can be soaked and gently washed in a minimal amount of water to either collect or remove the adhering material.

6. Placing the hair on the sticky area of a post-it can help keep the hair in place while cutting the hair. Using a scalpel, cut the root and/or sheath material (approximately 0.5cm) and carefully transfer to a 1.5mL or 2.0mL tube. Cut an equal and adjacent portion of the hair shaft and place into a separate 1.5mL or 2.0mL tube as the hair substrate control. Due to static electricity, use caution when transferring the hair fragment to the tube. A drop of water can be placed on the hair or in the tube when transferring to reduce the static electricity. Verify the presence of the hair(s) in the tube(s).

7. For DNA extraction of the hair sample, follow the procedure under Cellular Digestion of Biological Material [BIO.2.DNA.02](#).
Hair Chemistry, Structure, and Terminology

1. Chemistry: Hair is made of keratin protein (high in cystine and cysteine amino acids), sebum (lipids), water (can be in the medulla), melanin (a pigment made of long chain polymer) and trace mineral deposits which can be dietary dependent.

2. Structure:
   1. Cuticle: outer layer of overlapping scales -like stacked cups (patterns differ considerably from species to species.)
   2. Cortex: interior region and major source of the mechanical strength of the hair. The location of pigmentation that gives rise to hair color.
   3. Medulla: the core of the hair shaft composed of large cells of varying shape.

3. Terminology:
   1. Distal end (tip)
   2. Medial region (intermediate region between root and tip)
   3. Proximal end (near the root)

Fiber, Animal and Human Hair Characteristics

<table>
<thead>

<tr>
<td>Root</td>
<td>Shape, absent, broken, cut, putrid, growth phase</td>
<td>Varying root shape, typically tapered root end</td>
<td></td>
</tr>
<tr>
<td>Tip</td>
<td>Tapered, Frayed, Split, Rounded, Cut, Broken</td>
<td>Tapered distal tips</td>
<td></td>
</tr>
</tbody>
</table>

Definitions:
- **Buckling:** an abrupt change in direction along the shaft with or without slight twist
- **Convoluting:** a rotation or twist of the shaft, may loop or twine upon itself.
- **Shouldering:** changes in cross section of hairs
- **Undulation:** variations in diameter of the shaft (a wavy form)
- **Splitting:** longitudinal separations along the shaft

General Characteristics of Human Hair from Different Body Parts

1. Head: shaft normally constant, cut/blunt distal end, can have longer lengths.
2. Pubic: buckling, twisting, undulations, flatter (trough). Root typically has a type of flag (fatty root) and usually naturally tapered tip. Common to have frayed tips.
3. Limb: fine diameter, small root, can have frayed areas due to friction.
4. Beard: variations in color, medulla, coarse, diameter (buckling, shouldering)
5. Eyelash/eyebrow: taper down at root end, small rounded roots and tip tapers abruptly.
6. Axillary (underarm): looks like pubic, less buckling and finer diameter. Coarseness due to androgen levels. Root has fatty tissue even though telogen (similar to pubic). Tips tend to be worn, blunt, drawn out and lack pigment.

Gross Racial Characteristics

Due to much variation and cross-over between races, these are to be considered general racial characteristics.

1. Caucasian: Moderate shaft diameter with minimal variation. Sparse to moderate pigmentation with even distribution, thin cuticles, and oval cross-sectional shape.
2. Negroid: Fine to moderate shaft diameter with considerable variation. Densely distributed pigment in clumps (shaft may be opaque), shaft with prominent twist and curl, and flattened cross-sectional shape.
3. Mongoloid: Course shaft diameter with little or no variation. Densely distributed pigment arranged in clumps or in patches, thick cuticle, prominent medulla (broad and continuous), round cross-sectional shape.

Effects of Hair Treatments

1. Chemical (bleaching): damaged cuticles (ragged appearance), medulla can be filled with bubbles (H₂O₂) or oil.
2. Dyes:
   1. Vegetable dye (Henna): distinct yellow-reddish color in cortex, fills in medulla.
   2. Metallic (Greason formula): particles of lead sulfide caught in cuticle scales—just makes gray hair darker.
   4. Semi permanent: colors cuticle and partially in cortex, less damage to cuticle, many colors. Strange colors with transmitted light (pinkish).
3. Burned: keratin turns red and expanded bubbles can be observed in the shaft.
DNA Background

1. Hair embryology

   1. At 9 to 12 weeks gestation, a discrete group of ectodermal skin cells gather and begin a downward growth to form the beginnings of the hair follicle called a hair peg. At the same time a second group of cells gathering below the ectoderm are forming the dermal papilla in the mesoderm. The hair peg grows downward into a bulbous mass of cells and encloses the dermal papilla, thus completing the formation of a follicle.

   2. The dermal papilla is the driving force behind the hair growth. The dermal papilla directs cell division of the ectodermal matrix bulb cells (root bulb). The matrix bulb cells are what feed the growing hair shaft. The dermal papilla does not contribute cells to the shaft. A plucked hair with follicular material adhering to it is usually of ectodermal origin, however there may be mesodermal tissue present if a complete bulb is present.

   3. The formation of the hair follicle is a clonal selection of cells from the ectoderm and each hair follicle is independent of the other. An individual hair which may have undergone a mutational event can exhibit a genetic variation independent of other hairs or other cells in the body. Thus, a single locus variation from a reference sample should not be viewed as an elimination.

2. Heteroplasmy

   1. Heteroplasmy is a heterogeneous pool of mtDNA molecules in the cytoplasm of the cell, in other words, a mixture of multiple (usually two mtDNA sequence types in a single individual.)

   2. The rate of turnover of the matrix cells is greater than that of any normal tissue with the possible exception of bone marrow. In contrast, melanocytes in the hair bulb divide slowly. The cortical cells carry their own mitochondria and pick up melanocyte mitochondria from the bulb as the cortical cell migrates to the shaft. Cortical cells in the shaft thus could carry at least two populations of mitochondria. Melanocytes continue to contribute mitochondria to the shaft during the anagen phase while once the cortical cells differentiate they cease mitotic divisions (thus no new daughter cells).

   3. Thus, a single hair shaft can have varying ratios of heteroplasmy along the length of the shaft or from another hair originating from the same follicle.

   4. The heteroplasmy can be detected when the minor component is 10 to 20% of the overall mixture, otherwise goes undetected.

END OF DOCUMENT
Fetal Remains

The Biology Unit conducts DNA analysis on fetal remains (also referred to as products of conception) for criminal paternity cases.

Materials

- Forceps
- Petri dish
- Scalpel or razor blade
- Ruler
- Digital Camera
- Stereo microscope
- 0.9% saline solution
- 2.0 mL tubes or 15ml Falcon tubes

0.9% Saline Solution

0.9g NaCl in 100ml sterile distilled water (refrigerate)

Storage

Fetal remains should be stored refrigerated and submitted to the laboratory immediately for examination. If the specimen cannot be submitted in a timely manner, the submitting agency should be advised to store the specimen frozen to prevent bacterial growth and decomposition of the biological material.

Refrigerated fetal remains should be examined within 1 week of collection. The specimen must be stored frozen if examination is not possible with the 1 week time frame.

Refrigeration beyond 1 week subjects the fetal remains to decomposition which compromises the quality and quantity of the DNA. The freeze-thaw cycle for a frozen specimen can result in cell lysis, causing commingling of the fetal and maternal DNA. In both cases, it can make the distinction between the fetus and mother's DNA more challenging, particularly when the fetus is <10 weeks old.

Age of fetus

Many submissions to the laboratory are from abortuses ≤ 8 weeks old which is considered the embryonic period. The abortion procedure typically obliterates the embryo, however extra-embryonic tissue can be recovered and typed in lieu of the embryo itself. Extra-embryonic tissues include the embryonic membrane/sac (amnion), the chorionic membrane/sac (chorion), the chorionic plate, villi, and the umbilical cord.

When possible, request medical personnel performing the procedure to separate the fetal tissue from the maternal tissue in abortuses <10 weeks old. Even for fetus 10 weeks or older, where fetal structures may be more easily identifiable, request medical personnel, when possible, to collect the fetus separately from the maternal material.

Extra-Embryonic Structures (Figures from Reference #1)
Tissue from late embryonic-period abortion
(A) Villous chorion  (B) Yolk sac  (C) Amnion

Chorionic villi from early fetal-period abortion

(A) Chorionic villi  (B) Fetus-side of chorionic membrane  
(C) Detached chorionic villi floating in saline solution.

Procedure

1. If the fetal remains are received frozen, thaw in the refrigerator and/or at room temperature when ready for examination. Thawing time in the refrigerator may take several hours and possibly overnight, thus plan accordingly. If thawing at room temperature, monitor frequently to minimize the amount of time the tissue is left at room temperature conditions.

2. The form or condition in which the abortion product is received can be varied due to the different abortion techniques used. Unless the fetal material has been previously segregated by medical personnel, the fetal and maternal material will be commingled.

3. Place the aborted tissue or portions of the tissue into a petri dish filled with cold saline solution. The saline serves as a liquid medium to wash away extraneous fluids/materials and helps in the segregation of fetal tissue from the maternal tissue. If the fetus is less than 12 weeks old, a stereomicroscope may be needed to help identify the fetal tissue.

4. Separate the suspected fetal tissue from the maternal tissue by transferring the fetal tissue to another petri dish containing cold saline solution. Segregate as much of the identified and suspected fetal tissue as possible into the container.

5. Photograph the suspected fetal tissue in the petri dish with a scale, if desired. This may be done through the stereo microscope, speckfinder, or directly from the camera, depending on the magnification needed for documentation. See BIO.1.BIO.02 for visual, instrumental, and microscopic examinations.

6. When the segregation process is completed, sample a portion (approximately 2-3mm) of the suspected or identified fetal tissue and place into a 2.0 mL tube. Several samples may be needed when the examiner is uncertain and/or the fetal material cannot be readily identified due to the age of the fetus.

7. Samples selected for further DNA analysis will follow the Cellular Digestion of Biological Material procedure, BIO.2.DNA.02. Overnight digestion and additional Pro K is recommended to ensure complete digestion of the tissue samples. Once digested the samples may follow any available extraction method.

8. Once the sample selection process is completed, remove the segregated fetal material from the saline and transfer the tissue to a 2.0 mL tube or a 15 mL Falcon tube. Do the same with the maternal material or return the maternal material back to the original specimen container. Retain the fetal material in its segregated state in case additional testing is needed. Store all samples frozen. NOTE: The fetal and maternal material should not be stored frozen in saline solution or any other type of preservative.

References

Human Remains/Missing Persons

The Biology Unit may conduct examinations to assist in identifying human remains or missing persons. To identify the remains through DNA analysis, the DNA from the remains needs to be either compared to a known DNA reference sample from the victim or compared to family members of the victim. Secondary DNA reference samples, known to be from the victim, such as personal items (hairbrush, toothbrush, lipstick, etc) or medical specimens can be used, if available, to be compared to the human remains. When using a secondary reference, it is very important to establish that the personal item being used was only used by the victim or rarely used by someone else. Family reference samples may be needed to confirm that the personal item is from the missing person.
DNA profiles developed from human remains can be entered into CODIS and searched against family members of the missing person or can be compared directly against close family members. The closer the family relationship to the victim, the more likely a match can be made. The following is a list of family reference samples that could assist in identifying human remains, in order of preference:

1. Both parents or a known identical twin
2. One parent, spouse and children
3. Children and spouse
4. One parent and sibling
5. Siblings (two or more)

Human remains that are too badly decomposed will require the examiner to test alternate types of tissue, such as teeth, bones and nails to assist in identifying the individual.

Teeth

Teeth may be collected at a crime scene or removed from human remains. The quality of the teeth will be dependent on the environmental conditions of which the teeth were exposed.

Teeth are the hardest tissue in the human body and can even withstand fire. Teeth are divided into three sections; crown, neck, and root. The crown is the outer portion of the tooth above the gum. The neck is the portion within the gum line and the root is the portion below the gum. Teeth are composed of four distinct tissues: enamel (hard outer covering), dentin (inner layer below the enamel), cementum (hard covering over the root that attaches to the jaw), and pulp (located in the center of the tooth). The pulp contains blood vessels and nerves that supply the tooth, thus the pulp contains the DNA used for identification purposes.

Procedure

1. Gently wash the tooth in water to remove any material that may be adhering to the exterior of the tooth. If not already cracked open, crush the tooth to expose the pulp. Soaking the cracked open tooth in sterile water or saline may hydrate the pulp to help further identify the pulp portion of the tooth.
2. Place the pulp or cracked open tooth directly into a 2.0 mL tube for further DNA analysis. Follow the Cellular Digestion of Biological Material procedure, BIO.2.DNA.02. Spin down insoluble/undigested material prior to extraction.

References

Bone

Bones typically will be collected at the scene of a grave site of human remains or from a decomposed body, where other reference samples are not likely to be viable for DNA testing. The quality and quantity of DNA from the bone will be dependent on the environmental conditions of which the bone was exposed. The Department of Justice's Missing Persons Program may be consulted and may be utilized for DNA typing.

Bone is a type of hard living connective tissue. Bone is composed of a collagen, phosphate, magnesium, and calcium arrangement. Bone marrow is contained in the medullar cavities and is the portion of bone that can be used for DNA analysis. A rib or long bone is a preferred source for DNA analysis.

Procedure

1. Shave, crush or saw the bone using the best tool for the task. The tools, such as a saw blade or shaving device will be used on a one-time use basis when the tool cannot be thoroughly cleaned for repeated use. Order replacement blades or shaving devices as needed.
2. Place bone fragments directly into a 2.0mL tube for further DNA analysis. Follow the Cellular Digestion of Biological Material procedure, BIO.2.DNA.02. Spin down insoluble/undigested material prior to extraction.

References

Fingernails

Fingernails and toenails can contain trace evidence associated with the crime scene or possess biological material transferred from another individual. The trace evidence may be deposited as a result of casual contact with another person, or more so when an individual's hands or feet have made prolonged or aggressive contact with another individual. Hands that have entered an orifice will have an even greater chance of having transferred biological material.
Limitations and Challenges:

1. In general, the biggest factor to contend with is that the majority of biological material recovered from an individual's nails will be from the person from whom the sample was taken.
2. The level of biological material/DNA deposited may vary across each nail, thereby presenting a challenge in determining which nail and/or how many nails to select for subsequent analysis.
3. Fingernails are collected in various ways (e.g. clipping, scraping and swabbing) adding additional variation to the quantity and quality of trace evidence collected.

General Guidelines:

1. Case circumstances and the type of evidence will influence the selection and processing of the nails. The following are general guidelines for examining and processing fingernails and may be altered depending on the needs of the examination.
2. Inventory and document the condition of the nails (e.g. number of fingernails and any obvious debris, trace material, or suspected biological fluids, such as blood.)
3. Using a stereo microscope, visually inspect the scrapings, swab, or clipping for any adhering trace or biological material.

Using Fingernails for Evidentiary Purposes

Clippings

1. Examine the distal edge of the nails. If suspected biological material is observed, use forceps or a swab to collect, if possible, and place into a tube and process separately from the remaining nail(s). Remove any trace material prior to further testing the nails. If not possible to remove or swab, place entire nail clipping into a tube and follow procedure below.
2. If no obvious foreign material is observed, swab or place one or more of the nail clippings (depending on case circumstances and analyst discretion) into a tube(s) and follow procedure below.
3. Clippings from the right and left hand should be analyzed separately.

Procedure:

1. To remove possible foreign material on the nail clippings, submerge clippings in sterile water and allow to soak 5-10 minutes at 4°C (refrigerator or ice bath).
2. Alternatively, place the nail(s) in digest buffer and briefly digest (without the addition of DTT) the potential foreign cellular material adhering to the nail(s).
3. Occasionally vortex and pulse spin the tube to agitate and loosen foreign material that may be adhering.
4. After soaking or digesting, remove undigested nail(s), place in a spin basket and centrifuge 1-2 minutes to collect any residual foreign cellular material from the nails.
5. Save the remaining undigested nail for further digestion, if necessary. See "Using Fingernails as a Known Reference Material" below.
6. Proceed with DNA extraction on the removed trace material and/or the undigested nail, as needed. See Cellular Digestion of Biological Material BIO.2.DNA.02.

Scraping Procedure:

1. Visually inspect the loose scrapings and the scraping mechanism using a stereo microscope for obvious biological material, such as blood. If observed, collect separately from the remaining scrapings debris.
2. Otherwise, collect any observed scrapings and debris adhering to the scraper onto a swab and add any loose scrapings directly into the tube.
3. Alternatively, a portion of the scraper stick containing the observed debris may be added directly into the tube and removed after cellular digest.
4. Scrapings from the right and left hand should be collected and analyzed separately.
5. Proceed with DNA extraction.

Interpretation

DNA alone will not answer the question regarding how or why DNA from another individual is present on the victim or suspect's hands. Other known investigative factors, such as scratch marks or digital penetration may aid in the association between the trace material and the crime.

Using Fingernails As a Known Reference Material

Fingernails and toenails can be a source of DNA to assist in identifying an individual, whether the nail is left at the scene of a crime or from unidentified human remains.

Procedure

1. Visually inspect the nail(s) for trace evidence, if needed. This may require a stereo microscope for better magnification. If trace is present, collect for preservation. See "Using Fingernails for Evidentiary Purposes" above.
2. Clean nail with sterile distilled water to remove any adhering material (considered not to be of evidentiary value).
3. Cut the nail into several small pieces and place directly into a 2.0 mL tube. More than one nail may be needed to produce sufficient quantity and quality of DNA to produce a profile.
4. The nail can then be digested for DNA following the "reference" protocol under Cellular Digestion of Biological Material procedure, BIO.2.DNA.02.

References

I. The Biology Unit adheres to the Division's Discovery Request Policy, FSD.45. Additional laboratory procedures pertaining to discovery requests are found in the Clerical Manual, CLER.CRIM.11.

A request will be considered a discovery request any time the request is for documents and records beyond the laboratory report. A LIMS request is generated for all discovery requests.

DISCOVERY REQUEST GUIDELINES

A. Discovery requests must be in some form of writing and must be received from or routed through the District Attorney's Office. If a discovery request is received directly from the Public Defender’s Office or from a private attorney, advise the requestor to submit their request to the District Attorney's Office.

B. If staff receive a discovery request directly, the request needs to be routed to clerical staff or to the Supervisor to open a request in LIMS. A copy of the discovery request will be imaged in LIMS. Staff will coordinate with clerical staff and/or the Supervisor for the preparation of appropriate discovery materials.

C. Discovery requests are to be completed in a timely manner, when possible. Up to 5 business days may be necessary to complete a Basic and Standard Discovery. A minimum of 10 business days may be needed to complete an Extensive Discovery Request. Additional time may be required when the requested materials are extensive in nature and depending on the availability of laboratory personnel to gather the requested materials.

D. Extensive discoveries will be evaluated for scope, relevance, and reasonableness of the request. Additional discussions with the requester may be needed. If a request or portion of the discovery request cannot be met, the DA will be informed verbally or it will be conveyed in the written discovery report.

E. The technical portions of a discovery request typically will be completed by the analyst who authored the report. If the analyst is not available or is no longer employed by the laboratory, a Supervisor or designee may be assigned the discovery request. Clerical typically will prepare the non-technical portions of a discovery, such as copies of reports, notes and chains of custody.

F. Staff DNA Profiles will not be released as part of a discovery request. When a contamination event occurs that involves a staff member’s DNA, the incident is documented as part of the note packet, as well as its impact on reporting the results.

G. If a case involves a CODIS hit, the relevant CODIS information and records pertaining to the CODIS Hit are released as part of the note packet. Any DNA records retained within the Local CODIS database, other than those pertaining to the immediate case, cannot be released for discovery. The laboratory is required to abide by State and Federal Law regarding the release of DNA records from CODIS.

H. A discovery may include a request for resumes from the examiner and reviewers of the report. A Statement of Qualifications or a curriculum vitae (CV) from the author of the report will be provided. Technical and administrative reviewers are not considered co-authors to a report. The reviewers additionally are not considered co-authors of the examinations or the case notes, therefore a Statement of Qualifications from the reviewer(s) will not routinely be provided unless the reviewer is testifying for the examiner who did the work.

CATEGORIES OF DISCOVERY
The Biology Unit typically encounters three types of discovery; Basic, Standard DNA, and Extensive DNA.

1. Basic Discovery
A Basic Discovery typically entails a request for the examiner's reports and bench notes. The request may also include a request for chains of custody and other administrative records in the case file.
An electronic Chain of Custody can only be provided for the time the evidence was in the custody of the Laboratory. If the evidence is still at the Laboratory, a hard copy of the chain of custody on the package can be provided, if necessary.

II. **Standard Discovery**
A Standard Discovery request typically entails those materials listed as part of a basic discovery as well as a request for electronic DNA data files associated with the generation of the DNA results.

Prior to the release of electronic run files, DNA profiles or electronic data files not associated with the requested case are to be removed, where possible.

Electronic data files (qPCR files and STR typing files) require specialized software to view the results. The laboratory is not responsible for providing this software. A Standard Discovery typically consists of the following:

A. Quantification data files (qPCR).
B. DNA data files, such as sample files, injection lists, sample sheets, project files, matrices, and parameter files.
C. Frequency tables relied upon for statistical calculations. Reference to the published scientific journals relied upon for the frequency tables is included in the case notes.
D. Photos

III. **Extensive Discovery**
An Extensive Discovery entails providing copies of materials that extend beyond a standard discovery. The scope of the discovery request will be evaluated for relevancy and reasonableness. Due to the potential magnitude and volume of materials associated with this type of discovery request, additional time must be allotted to gather the material. When found to be relevant and reasonable, the following requested materials may be provided:

A. Audits: Audits will be limited to the most recent and completed audit bracketing the examination dates.
B. Proficiency tests: Proficiency tests will be limited to the most recent and completed proficiency(s) bracketing the examination date(s).
C. Unexpected Results or Events: Unexpected results or events are documented as part of the case notes. Corrective Action documents specific to the associated case will only be provided upon receipt of a subpoena or Subpoena Duces Tecum. See FSD.45 for further details.
D. Technical Unit Manuals: Manual will be limited to those relevant to the tests and analysis performed. For example, the CODIS manual will not be released if a CODIS profile was not part of the examination.
E. Validation Studies: Validation studies will be limited to those applicable to the tests and analyses relied upon during the examination process. Validation documents will be limited to the Validation Summaries.
F. Equipment Manuals: Equipment manuals will be limited to those applicable to the tests and analyses performed. Manuals provided will be limited to those available to the laboratory in an electronic form. Hard copy manuals can be viewed at the laboratory.

G. Training and QA/QC Manuals: These materials will be limited to the relevant examinations conducted.
H. Logs: Reagent and equipment logs will not be provided. These materials may be viewed at the laboratory in lieu of providing copies for discovery and will be limited to those relevant to the examinations conducted.
I. Any request for materials beyond what is provided above may be viewed at the laboratory in lieu of providing hard copies or electronic copies.

IV. **Discovery Procedures:**
A. Open a LIMS request under the relevant laboratory number. A written request for the discovery must be submitted. The request may be in the form of an email, fax, or official discovery request letter.
B. Attach a copy of the discovery request as an image in LIMS and relate it to the new request.
C. Create a **single copy** of the requested discovery materials. The materials may be prepared in paper copy, on CD/DVD, or provided electronically via email or ARIES. The District Attorney’s Office is expected to review the materials and make copies for distribution to the defense counsel.
D. Write a lab report detailing the discovery materials that were provided. The report should include 1) who requested the discovery, 2) what materials were requested and what materials were provided, and 3) how the materials were distributed (paper copy, email, CD/DVD, ARIES). A Supervisor or designee will review the report and the discovery materials prior to release.
E. Once the discovery materials and report have been administratively approved, the discovery materials may be released to the District Attorney's Office.

F. If the materials are provided via paper copy or CD, complete a Document Receipt for the recipient to sign. If the materials are provided via ARIES, the materials must be imaged under the request in LIMS and released via "I-Results". Release via "I-Result" must be after the discovery has been administratively reviewed.

G. The materials and receipt may be placed in the will-call box in the clerical area for pick-up. The signed Document Receipt is retained in the case file as an administrative record.

H. Place the administratively reviewed report with a copy of the discovery request letter in the report bin located in the clerical office to be filed.

END OF DOCUMENT
I. Digestion protocols for the release of DNA from biological specimens or from evidence containing biological material.

A. Materials:

1. Steam sterilized polypropylene plastic tubes (1.5 or 2.0 mL).
   - Qiagen Investigator Lyse & Spin Basket Kit
   - Single channel pipettes (10µL, 20 µL, 200 µL, 1000 µL).
   - Pipette tips, barrier filtered.
   - Spin baskets
   - Stain Extraction Buffer (BIO.5.QAQCF.23), aliquoted for single use or a batch in 15 mL tubes.
   - Proteinase K (20 mg/µL), (BIO.5.QAQCF.21), aliquoted for single use or a batch in 0.5 mL tubes.
   - Dithiotheritol (DTT), 4M, (BIO.5.QAQCF.22), aliquoted for single use or a batch in 0.5 mL tubes.
   - Tween 80 (BIO.5.QAQCF.27), aliquoted for single use or a batch in 15 mL tubes.
   - DNase I (BIO.5.QAQCF.28), aliquoted for single use or a batch in 0.5 mL tubes.
   - EDTA (BIO.5.QAQCF.37), aliquoted for single use or a batch in 1.5 mL tubes.
   - CaCl$_2$ + MgCl$_2$ (BIO.5.QAOCE.41), aliquoted for single use or a batch in 1.5 mL tubes.
   - Carrier RNA, stock 10 µg/µl (BIO.5.QAQCF.35)
   - Christmas Tree stain (BIO.1.BIO.10)

B. Digestion of biological material

1. Specimens in need of protein and cellular recovery for screening characterization prior to DNA analysis need to follow the procedure "Protein & Cellular Material Recovery: An Integrated Method for DNA analysis". See BIO.1.BIO.09 or for automated recovery on the Versa 1100 see section "Recovery of Proteins and Cellular Material Protocol" below.

2. Specimens which have previously undergone protein and cellular recovery will be in the form of a cell pellet, in approximately 50 µL of sterile water. At least one reagent blank (RB) will accompany each case's set of evidence to monitor for potential contamination and quality issues throughout the analysis process. The DNA analyst may create their own reagent blank by adding 50uL of the sterile water lot used for protein and cellular recovery to a reagent blank or use an RB that was created during biological screening. More than one reagent blank may accompany the sample set at the analyst's discretion.

3. Specimens intended to be directly digested, without prior protein and/or cellular recovery, will be placed directly into a 2.0 mL dolphin nose tube or alternatively into a Qiagen Investigator Lyse & Spin Basket Kit tube. At least one reagent blank (RB) is required to be digested with each set of evidence samples per case.
   a. If using the Qiagen Investigator Lyse & Spin Basket Kit, add the specimen directly into the spin basket. **NOTE: The Qiagen Investigator Lyse & Spin Basket Kit can not be used for differential digestions.**

4. Samples anticipated to possess low or limited DNA quantities, such as touch DNA samples should be handled, digested, and extracted separately in time or space than samples containing high quantities of DNA.

5. Samples known to have originated from the suspect, such as a penile swab must be handled, digested, and extracted separately in time or space then the samples originating from the victim, such as a vaginal swab.

6. Reference samples will be handled, digested, and extracted separately in time or space than the evidence samples and require a reference reagent blank (RBR) to accompany the reference extraction set. A single RBR is sufficient for any reference set.

7. At minimum, all reagent blanks are to be carried through the extraction process. At least one reagent blank per evidence sample set and one RBR per reference sample set is required to accompany the samples through the amplification process. Having additional extracted reagent blanks available allows additional amplifications to be conducted, if needed, using either current or future technologies.

8. A quality control sample (QC specimen) may be included with the digest of the evidence sample set at the analyst's discretion. The QC sample will be processed, at minimum, up to the quantification stage to monitor the digestion & extraction process, particularly for low quantity or low quality DNA specimens. A QC sample may
be processed through every step of the DNA analysis process. See Quality Control Sample procedure, BIO.5.QAQC.22 for additional information.

C. Combining Samples

1. Unless there is a reasonable expectation of samples originating from a common source, such as duplicate vaginal swabs, known reference samples (blood, bone, teeth, etc.), or same touch DNA item (for example, multiple swabs collected from the same steering wheel) samples/stains from different locations on a given evidence item should not be combined.

2. Occasionally a sample may not fit into a single 2.0mL tube. These samples may be digested in separate tubes and combined prior to or after DNA extraction. Reagent blanks must contain the same volume of reagents as the combined samples.

D. Procedure: Note: The below listed volumes may need to be altered to accommodate the size of the sample.

1. If extracting using the "Trace Protocol" of the EZ-1 Robot, see BIO.2.DNA.04, and add:
   a. 200µL stain extraction buffer (SEB) or Tween 80
      10µL Pro K (20mg/mL)

2. If extracting using the "Large Volume" protocol of the EZ-1 Robot, see BIO.2.DNA.04, and add:
   a. 400-500µL stain extraction buffer (SEB) or Tween 80
      10µL Pro K (20mg/mL)

3. For samples such as hair, teeth, bone, fetal tissue, and nails, add 10µL of 4M DTT.

4. For samples digested using the Qiagen Investigator Lyse & Spin Basket Kit the reagents are added directly into the spin basket portion of the tube.

5. Digest samples for a minimum of 2 hours to overnight, at approximately 56°C.

6. After removing samples from the heat block, spin down the tubes briefly to remove condensation from the lids. Using a toothpick or other device, agitate and tease the substrate material to loosen cells from the substrate material.
   a. If using dolphin nose tubes: Remove and place the specimen substrate into a spin basket and place the spin basket back into the 2.0 mL tube. Spin the sample tube in a centrifuge for 2-5 minutes at ~12,000 x g. The spin basket can then be discarded and the substrate can either be retained or discarded.
   b. If using the Qiagen Investigator Lyse & Spin Basket Kit tubes: Spin the tubes in a centrifuge for 2-5 minutes at ~12,000 x g. Upon centrifugation the holes in the bottom of the spin basket open up and allow the sample lysate to pass through. The spin basket can then be discarded and the substrate can either be retained or discarded.
   c. Indigestible or insoluble material remaining after digest, such as those from bone and teeth, should be centrifuged to pellet the material. Transfer the liquid digest to a new tube.

7. Continue to the EZ1 extraction procedure.

E. Differential Digestion of Biological Material

1. Prior to digesting samples containing both sperm and nucleated epithelial cells, the ratio of the non-sperm to sperm cells needs to be assessed. The cell content ratio is used to determine the digestion time needed to lyse the non-sperm cells, and is also used to determine the number of sperm cell washes to maximize the separation of the sperm DNA from non-sperm DNA.

   The cell content ratio may have been previously conducted during the process of biological screening or during the protein & cellular recovery process. See BIO.1.BIO.09. If the ratio has been evaluated, the samples can continue directly to the differential digest procedure.

   If the cell content ratio has not been assessed, prepare a cell pellet from the specimen sample, pipette 3µL of the pre-digested cell pellet onto a microscope slide, stain with Christmas Tree stain and assess the cell ratio. See BIO.1.BIO.02 for the staining procedure.

2. There are two methods that can be used for the differential digestion of samples containing sperm and non-sperm cells.

F. Differential Digestion Procedure:
To maximize sperm cell recovery prior to digestion, recombine the specimen substrate with the cell pellet into the 2.0mL tube. Use a toothpick or other device to aggressively agitate and tease the substrate material in order to loosen sperm cells from the substrate material.

1. **Add:**
   a. 400µL stain extraction buffer (SEB)  
      10µL Pro K (20mg/mL)
2. **Non-Sperm Cell Digest:** Incubate the specimen sample(s) ~ 1 - 2 hours (depending on the epithelial cell concentration) at approximately 56°C. Samples with low quantities of nucleated epithelial cells should be digested at the shorter time interval (i.e 1 hour) in order to limit the amount of potential sperm cell DNA carry-over from sperm lysis into the non-sperm fraction.
3. After digestion, spin down the tubes briefly to remove condensation from the lid. Remove and place the substrate into a spin basket and place the spin basket back into the 2.0 mL tube. Centrifuge the samples for 2-5 minutes to pellet the sperm cells.
4. Remove the spin basket & substrate. The spin basket can then be discarded and the substrate can either be retained or discarded. While being careful not to disturb the sperm pellet, remove all except for ~50µL of the digested non-sperm cell DNA fraction and transfer to a new tube. Label the new tube as the "non-sperm fraction". The non-sperm fraction can be set aside or can continue to digest along with the sperm fraction digestion (see below).
5. Add 1 mL of sterile water to the sperm cell pellet. Re-suspend the cell pellet in the water by gently vortexing. Centrifuge for 3-5 minutes at ~12,000 x g. Being careful not to disturb the sperm pellet, remove and discard all except for ~50µL of the supernatant.
   a. Repeat sperm pellet wash step 3 - 5 times leaving ~50µL each time. The number of wash steps needed can be varied at the analyst's discretion and may depend on the original cell content ratio, fragility of the cells (i.e., due to age of stain) or other environmental factors.
   b. After the final wash, re-suspend the sperm pellet in the ~50µL final wash solution. Transfer 3µL of the sperm pellet suspension to a microscope slide, dry, and stain with Christmas Tree stain.
   c. Evaluate the cell content of the post-digest slide. The cell pellet should not have any identifiable nucleated epithelial cells. If undigested nucleated epithelial cells are present, repeat the non-sperm digestion procedure and digest for another 20 to 30 minutes. Repeat the sperm pellet wash steps above and reassess. Repeat, until all nucleated cells have been digested.
6. **Sperm Cell Digest:** Digest the sperm pellet by adding the following:
   Add:
   a. 400µL stain extraction buffer (SEB)  
      10µL Pro K (20mg/mL)  
      5-10µL of 4M DTT
   b. Digest the sperm fraction(s) at 56°C for a minimum of 3-4 hours, and preferably overnight. At the analyst's discretion, a fresh 10µL aliquot of Proteinase K may be added to the samples prior to the overnight incubation. The separate non-sperm fractions may be additionally digested overnight with the sperm fractions.
7. Continue to the EZ1 extraction procedure.

G. **Selective Degradation Differential Digestion Procedure**

1. **Non-Sperm Cell Digestion**
   a. To maximize sperm cell recovery, recombine the specimen substrate with the cell pellet into the 2.0mL tube prior to digestion. Use a toothpick or other device to aggressively agitate and tease the substrate material to loosen cells from the substrate material.
      i. **Add:**
      
      510µL Tween 80 Buffer  
      10µL Pro K (20mg/mL)
   b. Incubate the sample(s) ~ 30 minutes at approximately 56°C.
c. Spin down the tube briefly to remove condensation from the lid. Using a toothpick or other device, agitate and tease the substrate material to loosen sperm cells from the substrate material. Remove and place the specimen substrate into a spin basket and place the spin basket back into the 2.0 mL tube. Spin sample tube in a centrifuge for 2-5 minutes at ~12,000 x g to pellet the sperm cells.

d. Being careful not to disturb the sperm pellet, remove all except for ~ 50µL of the digested non-sperm cell DNA fraction and transfer to a new tube. The non-sperm fraction can be set aside for the extraction procedure. The substrate material may be retained or discarded.

e. Additional "washes" with Tween 80 may be conducted to further clean the sperm pellet. With each wash, add 400µL of Tween 80 to the cell pellet and briefly vortex, spin down, and discard all but ~50µL of the supernatant each time. Repeat as needed and retain the final cell pellet in 50 µL.

2. Post-digest Cell Content Determination

   a. Gently resuspend the sperm pellet in the 50 µL and transfer 3µL of the sperm pellet suspension to a microscope slide, heat fix, and stain with Christmas Tree stain. A post-digest slide must be made, but evaluating it is optional.

      i. If nucleated epithelial cells are present, repeat the non-sperm digestion procedure and digest for another 20 to 30 minutes. Repeat until all nucleated cells have been digested.

      ii. If the sperm cell pellet is clear of nucleated epithelial cells, estimate the sperm cell concentration in the 3µL examined. Retain the post-digest slide if probative biological material is present.

3. Non-sperm DNA degradation with DNase

   a. To the resuspended sperm pellet, add:

      i. 290µL Tween 80 buffer
         25µL CaCl2/MgCl2 solution
         15µL DNase I

   b. Degrade the non-sperm DNA in the sperm fraction for ~15 minutes at 56°C. **DO NOT VORTEX SAMPLES. This may cause loss in DNase activity.**

   c. Inactivate the DNase by adding 20uL EDTA. Vortex samples and let samples incubate at room temperature for ~10 minutes.

4. Sperm Cell Digestion

   a. Lyse the sperm cells by adding the following to the sperm fraction (SP):

      i. 10uL of ProK
         10uL of DTT

   b. Incubate for a minimum of 15 minutes or overnight at 56°C.

5. Continue to the EZ1 extraction procedure.

6. To accentuate the DNA recovery of low level DNA samples, 1 µg of carrier RNA (cRNA) may be added to the samples after digest, but prior to the extraction process. Refer to the extraction procedure BIO.2.DNA.04 for further information regarding the use of cRNA for low level DNA samples.

H. Differential Digestion using Selective Degradation on the Versa 1100

1. **Consumables**

   SlicPrep Plate (base plate, spin basket insert, and u-shaped collar)
   2.0 mL EZ1 flat bottom tubes
   Sterile wooden sticks
   96-well plate covers
   Microscope slides
   50uL non-conductive filtered pipette tips
   1000uL conductive filtered pipette tips

2. **Reagents**

   Tween Buffer (2% Tween 80, 20mM Tris HCl, 1mM EDTA)
   Proteinase K (20mg/mL)
   Dithiothreitol (1M)
   DNase I (1 U/µL in 40% glycerol, brought to volume with DEPC-treated water)
   CaCl₂ and MgCl₂ solution (5mM and 90mM, respectively)
EDTA (0.5M)
Sterile Deionized Water

3. The automated selective degradation differential digestion procedure is performed on the Versa 1100 using SlicPrep plates. Manual intervention will be required to centrifuge the SlicPrep plate, remove sample tubes and microscope slides from the instrument, and replace empty sample tubes onto the instrument. Nine-hour delays are programmed into the assay on the Versa to pause the procedure and allow the analyst to perform these manual steps.

4. There are two main protocols in the instrument software, one for the recovery of proteins and cellular material, and another for the differential digestion. The differential digestion protocol has twelve versions of it to reflect the options of running one to twelve columns of samples.

5. The SlicPrep plate is a 2.2mL 96 deep well plate that includes a 96-well spin basket insert, base plate, and a U-shaped collar. Samples are placed inside the wells of the spin basket insert. At the bottom of each well are seven 1mm holes that allow liquid to flow in and out of the insert during incubation. The U-shaped collar is used to create a 1cm gap between the insert and the base plate for centrifugation steps.

6. The spin basket insert should be placed in the correct orientation each time it is placed into the base plate. Two lines can be drawn across the surface of the spin basket to ensure proper orientation.

7. The DNase used in this protocol is contained in individual tubes without the divalent cation activators (Mg2+ and Ca2+) and is therefore inactive. Activated DNase will only be present inside of the SlicPrep plate. No liquid waste containing activated DNase will be generated in this protocol. All pipette tips are one time use only and are discarded in a waste container.

8. **Procedure**
   a. Launch the Versaware software on the desktop.
   b. Turn on the Versa by turning the red circular button on the bottom left corner clockwise.

9. **Reagent Drop Priming**
   a. The reagent drop is a system that dispenses reagents through a needle controlled by a valve for accurate volume dispensing. The needle is connected to thin tubing which is connected to a reagent bottle residing outside of the instrument.
   b. The reagent drop must be primed before each run to remove air from the sterile water tubing and water from the Tween 80 tubing.
      i. The Tween 80 tubing is stored filled with sterile water to prevent crystals from forming in the tubing. Ensure that the tubing is placed into the Tween 80 bottle (reagent bottle 2), select the Assay "Priming with Tween" and place a 96 deep well plate in position 11 on the Versa.
      ii. Prime the tubing for the sterile water used in the recovery of proteins and cellular material protocol to ensure air bubbles aren't present in the tubing. Run the "Recovery of Proteins and Cellular Material" program, highlight several wells in the software to dispense into (a sufficient amount to ensure all air bubbles are removed) and place a 96 deep well plate in position 11. Click "save", then press the green "play" button.

10. **Recovery of Proteins and Cellular Material Protocol**
    a. For each sample, cut the substrate into small pieces and place into a well of the SlicPrep plate spin basket resting in the base plate. For swabs, take half to a whole swab and cut into 4-5 smaller pieces. Carefully
place each piece into the designated location on the SlicPrep plate according to the **Differential Digestion Sample Sheet** in the DNA Worksheets workbook.

b. Each column will only contain samples from one case. The plate should contain at least one reagent blank per case.

c. Place the SlicPrep plate (without the U-shaped collar) in position 11 on the Versa deck.

d. Run the **"Recovery of Proteins and Cellular Material"** Protocol on the Versa by highlighting the procedure at the red arrow. Select the wells that contain samples in the Versa software, click "save", then press the green "play" button. The reagent drop pin will dispense 500uL of sterile water into each well.

e. Remove the SlicPrep plate, cover it, then incubate at 4°C 30 minutes to overnight. Make sure the samples are completely submerged in the water.

f. After removing the plate from the 4°C incubation, agitate each sample manually with a sterile wooden stick and place the septa back on the plate.

g. Insert the U-shaped collar between the spin basket insert and the base plate.

h. Centrifuge for 6 minutes at 1,000 x g.

i. Remove the U-shaped collar and the spin basket of the SlicPrep plate. Carefully place the spin basket into a sterile holder (empty tip box).

j. Place the base plate in position 6 of the Versa deck. Place the appropriate number of labeled 2.0 mL EZ1 flat bottom tubes into the holders on deck 13, 14, and 15 of the Versa deck, as needed. Be sure to remove the tube caps.
11. Differential Digestion Protocol

a. Run the "Differential Digestion" Protocol by highlighting the procedure at the red arrow (select the procedure that has the correct number of columns based on the number of samples being processed), then press the green "play" button.

b. The instrument will transfer the aqueous extract from the base plate to the empty sample tubes and pause for 9 hours.

c. Remove the tubes of aqueous extract. Cap each tube and store at 4°C. These samples can be used for p30 or RSID saliva testing (see BIO.1.BIO.4 or BIO.1.BIO.5).

d. Vortex the proteinase K reagent tubes and load them into column 8 of the reagent block on position 1 of the Versa deck. All 4 tubes are necessary for 4-channel pipetting.

e. Place the spin basket insert containing the sample substrates back into the SlicPrep plate (without the collar or plate septa), making sure the drawn lines align properly for the correct orientation. Place the plate in position 11 of the Versa deck.

f. Click the “stop now” button to stop the 9-hour pause and resume the protocol.

g. The instrument will add 510uL of Tween buffer and 10uL of proteinase K to each well.

h. The SlicPrep plate will then be transferred by the instrument to the heating block and incubated at 56°C for 30 minutes with shaking. The instrument will then move the plate back to position 11 and pause for 9 hours.

i. During the 9-hour pause: Remove the SlicPrep plate and agitate each sample using its own sterile toothpick or sterile stick. After agitation, carefully remove and discard the toothpick/stick and add the plate cover back to the plate.

j. Insert the U-shaped collar between the spin basket insert and the base plate.
k. Centrifuge for 6 minutes at 1,000 x g.

l. Place the appropriate number of labeled 2.0 mL EZ1 flat bottom tubes into the holders on deck 13, 14, and 15 of the Versa deck, as needed, for the non-sperm fraction. Be sure to remove the tube caps.

m. Place the appropriate number of slides onto positions 7, 8, and 9 of the Versa deck, as needed. Be sure to label the slides.

n. Remove the U-shaped collar and the spin basket of the SlicPrep plate. Carefully place the spin basket into a sterile holder (empty tip box).

o. Place the base plate in position 6 of the Versa deck. Click the “stop now” button to stop the 9-hour pause and resume the protocol. The instrument will transfer the epithelial cell fraction from the base plate to the empty sample tubes. The instrument will then resuspend the pellet in the remaining 50uL liquid and transfer 3uL of each resuspended sample from the SlicPrep base plate to the post-digestion microscope slides. The instrument will now pause for 9 hours.

p. During the 9-hour pause: Remove the microscope slides and the tubes containing the non-sperm fraction. Cap each tube and store at 4°C. The slides can be processed now or at a later time. Refer to BIO.1BIO.04 and BIO.1.BIO.02 for post-digest cell content determination procedures.

q. Place the appropriate number of labeled 2.0 mL EZ1 flat bottom tubes into the holders on deck 13, 14, and 15 of the Versa deck, as needed, for the sperm fraction. Be sure to remove the tube caps.

r. Remove the proteinase K reagent tubes from the reagent block and vortex. Load the reagent tubes back onto column 8 of the reagent block in position 1 of the Versa deck.

s. Load the CaCl₂ and MgCl₂ salt solution (column 7), DNase (column 6), EDTA (column 5), and DTT (column 4) reagent tubes onto the reagent block in position 1 of the Versa deck. DO NOT VORTEX THE DNASE REAGENT TUBES!

t. Click the “stop now” button to stop the 9-hour pause and resume the protocol.

u. The instrument will add 290uL Tween80 buffer, 25uL CaCl₂/MgCl₂ salt solution, and 15uL DNase to the samples and incubate at 56°C for 15 minutes to destroy any remaining epithelial cell DNA.

v. Following the incubation period, the instrument will inactivate the DNase by adding 20uL EDTA to the samples in the SlicPrep plate and incubating for 10 minutes at room temperature to allow the EDTA to chelate all of the Ca²⁺ and Mg²⁺ divalent cations.

w. Sperm lysis will begin with the addition of 10uL proteinase K and 10uL DTT to the samples followed by incubation at 56°C for 15 minutes. The sperm fraction will then be transferred to the sample tubes. The instrument has now completed the protocol.

x. Remove the tubes containing the sperm fraction and proceed to DNA extraction of the epithelial cell and sperm fractions using the EZ-1 large volume protocol or store at 4°C to extract at a later time. Refer to
12. Post-Run Priming
   a. Prior to turning off the instrument at the end of the run, remove the tubing from the Tween80 and place it in sterile deionized water in reagent position 1. The Tween 80 might plug up the tubing if not flushed out after every run and filled with water.
   b. This can be done by selecting the Assay “Post Priming with Water” and placing a 96 deep well plate in position 11 on the Versa.

END OF DOCUMENT
I. Procedure for the purification, isolation, and concentration of DNA using a silica-coated magnetic bead technique.

A. Materials:

1. Steam sterilized dolphin nose microcentrifuge tubes (1.5 or 2.0 mL, and 0.5 mL) or Qiagen Lyse and Spin tubes
   Single channel pipettes
   Pipette tips, barrier filtered
   TE-4
   Qiagen EZ-1 Robot or EZ1 Advanced XL Robot
   Qiagen Investigator Kit Components:
   a. Extraction cartridges. (Caution: extraction cartridges contain chaotropic salts that are incompatible with bleach).
      Plastic 2.0 mL screw-cap, conical bottom tubes for cellular digests.
      Plastic 1.5 mL screw-cap tubes for DNA recovery.
      Reaction pipette / pipette holder.
      1 ug Carrier RNA

B. Protocol:

1. Fill out the extraction use/run log.
2. Pulse spin the cellular digest tube to ensure all digest fluids and condensation are collected to the bottom of the digestion tube.
3. For samples digested and contained in 2.0 mL dolphin nose tubes, transfer the digest fluid to a labeled EZ-1 robot sample tube (conical-bottom) and close the caps. Label a corresponding set of EZ-1 robot elution tubes. If samples are in a lyse and spin tube they do not need to be transferred to an EZ1 sample tube, however ensure the basket and substrate have been removed.
4. For samples predicted to have very low recovery of DNA, 1 µg of carrier RNA may be added to the digest sample to accentuate the recovery of DNA. See cRNA preparation below:
   Prepare a 1:10 dilution of the reconstituted stock of cRNA. Add 1µL to the digested sample, prior to extraction. Refer to BIO.5.QAQCF.35 for the preparation of cRNA stock.
5. Preparing the EZ-1 Instrument:
   a. Make sure the DNA Investigator controller card is located in the card slot of the instrument before the instrument has been turned on. (Do not insert the card once the instrument has been switched on.)
   b. Switch on the instrument by pressing the power switch in the back. The main menu will display the startup dialogue, prompting the choice of either "Start", "1-Tools", or "2-Tests."
   c. Select "1-Tools", then "3" to clean the pierce unit. Wait until the piercing unit moves forward and down before opening the door. Wipe the piercing unit with a kimwipe moistened with 70% ethanol and then a kimwipe moistened with distilled water. Press "ESC" to return the piercing unit to its original position. If the O-rings of the tip adapters are dirty, clean with a kimwipe moistened with water (DO NOT USE ETHANOL on the O-rings). Check the bottom tray and if dusty or precipitants are present, wipe the tray with deionized water or ethanol. To return to the main menu, press escape key twice.
   d. Press the "START" key to display the protocol menu. The Investigator card allows for four different protocols:
      i. Trace protocol (for use with digests of 200 µL volume).
      ii. Trace, Tip Dance protocol (for use when the substrate is still present).
      iii. Normalization (for normalized recovery of DNA quantity).
      iv. Large volume (for use with digests of up to 500 µL).
   e. Select either the Trace Protocol or the Large Volume Protocol depending on the volume of cellular digest. Trace-tip dance and normalization programs are not currently used.
   f. Select "TE" for the elution solution.
   g. Select "50µL" for the elution volume.
   h. The instrument will display messages to assist the user in setting up the tray and tip/tube rack.
   i. Follow the menu prompts to move through the set up menu.

Loading the Cartridge Tray Holder:

j. Remove the cartridge tray holder and tip/tube rack from the instrument.
   k. Load the DNA Investigator Kit Cartridges into the slots of the tray. Prior to loading the cartridges into the tray:
   Gently invert the Investigator Cartridges to mix the reagents and then tap the cartridges to bring the reagents to the bottom of the wells.
Ensure there is no precipitate observed in the buffer (well #1 of the investigator cartridge). If there is a precipitate present, dissolve by mild agitation at room temperature.

1. Prior to returning the loaded tray holder to the instrument, ensure each cartridge is seated properly in each slot. Return the tray holder to the instrument and make sure that the heat block well of each cartridge is seated correctly in the worktable.

## Loading the Tube & Tip Rack Holder:

m. Return the tube/tip rack holder back into the instrument to begin loading the sample and elution tubes, tips, and tip holders as illustrated below:

<table>
<thead>
<tr>
<th>Back of Instrument</th>
<th>Front of Instrument</th>
</tr>
</thead>
<tbody>
<tr>
<td>Row 4 (Sample Tubes)</td>
<td></td>
</tr>
<tr>
<td>Row 3 (Empty)</td>
<td></td>
</tr>
<tr>
<td>Row 2 (Pipette tip &amp; holder)</td>
<td></td>
</tr>
<tr>
<td>Row 1 (Elution Tubes)</td>
<td></td>
</tr>
</tbody>
</table>

n. Each column represents the set-up for each sample. Elution tubes (either microcentrifuge tubes or Qiagen EZ1 provided tubes) are loaded in row 1; Pipette tips and holders are loaded in row 2; row 3 is left empty; the EZ-1 sample tubes containing cellular digests are loaded in row 4. If continuing on to quantification set up by the Nimbus robot the elution tubes need to be 1.5 mL microcentrifuge tubes.

o. Load the correct number of tip holders into the tube/tip rack. Without touching the ends of the pipette tips, insert a pipette tip into each holder; Row #2 of the rack.

p. Starting from the left, load the sample digest, in a predetermined order, into row 4. Load the paired elution tubes in the same predetermined order into row 1. Working left to right, uncap the sample and its paired elution tube one paired set at a time. Place the caps onto a clean tissue in the same order as the tubes in the rack. Confirm that the position of each sample and elution tube is in the correct order as predetermined or preferred by the analyst. The analyst may use an extraction worksheet as a guide, if desired.

q. Verify all samples and sample tubes are in their proper order and in their proper position in the tray. Verify the tip holder is in its proper place and that there is a pipette tip in each holder. Once verified close the instrument door.

r. Press "START" on the keyboard of the Robot. Visually monitor the Robot until the pipette tips have been picked up from the tip holder. If the instrument fails to pick up or fully seat a pipette tip, stop the run immediately. Troubleshoot the problem and re-start.

s. The extraction protocol takes approximately 20 minutes to complete. When the extraction is completed, the instrument LCD displays "FINISHED". If it is necessary to extract another set of samples, press "ESC" to return to the "Protocols" menu. If you are finished extracting, press "STOP" twice to return to the home position.

t. Open the instrument door and starting from left to right, place a cap on the elution tubes and remove. Transfer the extracted DNA samples into labeled 0.5 mL tubes, if desired. Record the volume recovered. The DNA extracts are now ready for DNA quantification.

u. If concentrating DNA extracts prior to quantification, refer to BIO.2.DNA.07 for further information and instruction on concentrating the DNA extracts anticipated to have low DNA recovery.

v. Store extracts refrigerated or frozen for long term storage

w. The EZ1 robot can then be turned off

6. **Preparing the EZ-1 Advanced XL Instrument:**

a. Make sure the EZ1 Advanced XL DNA Investigator Flip-Cap controller card is located in the card slot located on the front of the instrument before the instrument is turned on. (Do not insert the card once the instrument has been switched on.)

b. Switch on the instrument by pressing the power switch in the back. The main menu will display the startup menu, prompting the choice of either "Start", "1-UV", "2-Man", "3-Test", or "4-Setup".

c. Press "2-Man" to select the manual function, then press "3" to clean the pierce unit, then press "START". Wait until the piercing unit moves forward and down before opening the door. Wipe the piercing unit with a kimwipe moistened with 70% ethanol, then wipe with a kimwipe moistened with distilled water. Close the EZ1 Advanced XL door and press "ENT" to return the piercing unit to its original position. If the O-rings of the tip adapters are dirty, clean with a kimwipe moistened with water. Check the bottom tray and if dusty or precipitants are present, wipe the tray with deionized water or ethanol. To return to the main menu, press "ESC".

d. Press the "START" key to display the protocol menu.

e. A message will be displayed asking if you would like to create a Report File. Press "ESC" to select No.

f. The Investigator card allows for four different protocols:

i. Trace protocol (for use with digests of 200 µL volume).

ii. Trace, Tip Dance protocol (for use when the substrate is still present).

iii. Normalization (for normalized recovery of DNA quantity).

iv. Large volume (for use with digests of up to 500 µL).
g. Select either the Trace Protocol or the Large Volume Protocol depending on the volume of cellular digest. Trace-tip dance and normalization programs are not currently used.

h. Select "TE" for the elution solution.

i. Select "50µL" or "40µL" for the elution volume.

j. The instrument will display messages to assist the user in setting up the tray and tip/tube rack.

k. Follow the menu prompts to move through the set up menu.

l. The software will ask: "Do you want to create a Report File?" Press "ESC" to select No.

Loading the Cartridge Tray Holder:

m. Remove the cartridge tray holder and tip/tube rack from the instrument.

n. Load the DNA Investigator Kit Cartridges into the slots of the tray. Prior to loading the cartridges into the tray:

a. Gently invert the Investigator Cartridges to mix the reagents and then tap the cartridges to bring the reagents to the bottom of the wells.

b. Ensure there is no precipitate observed in the buffer (well #1 of the investigator cartridge). If there is a precipitate present, dissolve by mild agitation at room temperature.

c. Prior to returning the loaded tray holder to the instrument, ensure each cartridge is seated properly in each slot. Return the tray holder to the instrument and make sure that the heat block well of each cartridge is seated correctly in the worktable.

Loading the Tube & Tip Rack Holder:

p. Return the tube/tip rack holder back into the instrument. Note there is a notch along the right side of the tray and corresponds with a peg inside the instrument to ensure proper orientation of the tray. Begin loading the sample and elution tubes, tips, and tip holders as illustrated below:

<table>
<thead>
<tr>
<th>Cartridge</th>
<th>Reagent Cartridge 1</th>
<th>Reagent Cartridge 2</th>
<th>Reagent Cartridge 3</th>
<th>Reagent Cartridge 4</th>
<th>Reagent Cartridge 5</th>
<th>Reagent Cartridge 6</th>

<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

a. Each column represents the set-up per individual sample. Elution tubes (either microcentrifuge tubes or Qiagen EZ1 provided tubes) ; Pipette tips and holders are loaded in row 2; the EZ-1 sample tubes or Lyse and Spin tubes which contain the cellular digests are loaded in row 3. Note: The lyse and spin tube cap must be securely tucked into the designated slot located between row 2 and row 3. If continuing on to quantification set up by the Nimbus robot the elution tubes need to be 1.5 mL microcentrifuge tubes.

b. Load the correct number of tip holders into the tube/tip rack. Without touching the ends of the pipette tips, insert a pipette tip into each holder; Row 2 of the rack.

c. Working left to right across the tray, load un-capped sample digest tubes in the order predetermined by the analyst, into row 3. Load the paired un-capped elution tubes in the same predetermined order into row 1. Place the caps onto a clean tissue in the same order as the tubes in the rack. Confirm that the position of each sample and elution tube is in the correct order as predetermined or preferred by the analyst. The analyst may use an extraction worksheet as a guide, if desired.

d. Verify all tubes are in their proper position in the tray. Verify the tip holder is in its proper place and that there is a pipette tip in each holder. Once verified close the instrument door.

e. Press "START" to start the protocol run.

f. The extraction protocol takes approximately 16 minutes to complete. When the extraction is completed, the instrument LCD displays "PROTOCOL FINISHED". Press "ENT" to select NEXT.

g. Open the instrument door and starting from left to right, place the correct corresponding labeled cap on each elution tube and remove. Transfer the extracted DNA samples to labeled 0.5 mL tubes, if desired. Record the volume recovered. The DNA extracts are now ready for DNA quantification.

h. A message will be displayed asking if you would like to perform a UV Run. Press "ENT" for YES or "ESC" for NO. If you choose to perform a UV run, you will be prompted to add a decontamination time between 20 and 60 minutes. If you choose not to perform a UV run, press "ESC" to return to the main menu. The EZ1 XL can then be shut off.

i. If concentrating DNA extracts prior to quantification, refer to BIO.2.DNA.07 for further information and instruction on concentrating the DNA extracts anticipated to have low DNA recovery.

J. Store extracts refrigerated or frozen for long term storage

C. Clean up and Disposal

1. Dispose of used reagent cartridges and sample tubes in a chemical waste container. Do not add or mix with materials containing bleach to the container.
2. Wipe down surfaces of the tray and tip rack with deionized water or ethanol.
3. Clean piercing unit.

D. Combining Extracts:
   1. When there is reasonable expectation of samples originating from a common source, such as duplicate vaginal swabs or known reference samples (blood, bone, teeth, etc.) separate extracts may be combined to increase the amount of DNA template for amplification.
   2. Separate extracts from different locations on a given evidence item should not be combined.

END OF DOCUMENT
I. Protocol for Quantification of Human DNA using PowerQuant

A. Materials

Promega PowerQuant System
Applied Biosystems 7500 Real-Time PCR System
Applied Biosystems HID Real-Time PCR Analysis Software v. 1.2
Single channel pipettes: 2µL, 10µL, 20µL, 100µL, 200µL, 1000µL and/or repeat pipettor
Pipette tips, barrier filtered
96-Well Optical Reaction Plates, P/N 4306737
Optical Adhesive Film, P/N 4311971
Strip caps
MicroAmp Splash Free Support Base, P/N 4312063
Microcentrifuge tubes

B. Introduction

1. The PowerQuant System is a five-dye, four-target hydrolysis probe-based qPCR multiplex that amplifies multicopy targets to quantify the total human and male DNA present in a sample. The system also amplifies an additional multicopy target to assess the degree of degradation and an internal PCR control (IPC) to detect inhibitors in an amplification reaction. The following procedure was adapted from the PowerQuant System Technical Manual published by Promega for use of the PowerQuant System with the Applied Biosystems 7500 Real-Time PCR System and HID Real-Time PCR Analysis Software Version 1.2.

II. Protocol PowerQuant System

A. Contents of the PowerQuant System:

1. PowerQuant 20X Primer/Probe/IPC Mix: Includes all primers and probes, Internal PCR Control and a passive reference dye.
   a. Primers and probe for the autosomal DNA target: The primers and FAM dye-labeled probe are used to amplify an 84-base pair amplicon.
   b. Primers and probes for the Y-Chromosomal target: The primers and CAL Fluor Gold 540 dye-labeled probes are used to amplify two multicopy loci (81bp and 136bp amplicons).
   c. Primers and probe for the degradation target: Quasar 670 dye-labeled probe detects the presence of a longer amplicon (294bp) derived from a different region of the same locus as the autosomal target. Due to its greater length, the degradation amplicon is more susceptible to degradation and the presence of inhibitors. The ratio of DNA concentrations determined with the autosomal and degradation targets ([Auto]/[D] ratio) can be used to evaluate the degree of degradation.
   d. Primers, probe and template for the Internal PCR Control: The TMR dye-labeled probe of the PowerQuant System detects the Internal PCR Control. The primers produce an amplified product that is 435bp. Amplification performance of the IPC is used to detect inhibitors in the sample. This is the longest target in the PowerQuant System, making the IPC more susceptible to inhibitors than the other targets in the multiplex.
   e. Passive reference dye: The CXR dye is used as a passive reference. The CXR dye is included in each amplification reaction. Data from the other dye channels are normalized to this signal.

2. PowerQuant 2X Master Mix

3. PowerQuant Male gDNA Standard: Consists of pooled human male DNA supplied at 50 ng/µL. Serial dilutions of this DNA standard are amplified in the same plate as the unknown samples, and the results are used to
generate a standard curve for the autosomal, Y, and degradation targets.

4. **PowerQuant Dilution Buffer**: This is supplied as the diluent for serial dilutions of the PowerQuant Male gDNA Standard to create the standard curve.

5. **Amplification Grade Water**

B. **Storage Conditions**: Store the PowerQuant System at -30°C to -10°C in a nonfrost-free freezer. Store the Male gDNA Standard overnight at ~4°C prior to the first use and do not refreeze. For short-term storage (less than 1 week), store the other components at 2-10°C. Minimize the number of freeze-thaw cycles. The 20X Primer/Probe/IPC is light sensitive and must be stored protected from the light.

C. **Preparation of Human DNA Standards**: Preparation of Human DNA Standards: perform serial 25-fold dilutions of the PowerQuant Male gDNA Standard, then amplify these dilutions to create a four-point standard curve in duplicate to determine the concentration of autosomal, Y, and degradation targets in unknown DNA samples. Precise serial dilutions of the Male gDNA Standard is essential to accurately quantify unknown DNA samples. Proper care must be taken to mix and pipet each DNA standard dilution.

1. Store the PowerQuant Male gDNA standard overnight at ~4°C prior to first use. If necessary, thaw the PowerQuant Dilution Buffer completely.
   a. Note: After the initial thaw, store the Male gDNA Standard and Dilution Buffer at 4°C.

2. While working in the PCR PrepStation hood, vortex the Male gDNA Standard at least three times at high speed for ~10 seconds each time.

3. Label three microcentrifuge tubes with the following concentrations: 2 ng/µL, 0.08 ng/µL and 0.0032 ng/µL. Additionally, label each tube with the date and the initials of the preparation.

4. Prepare fresh serial dilutions of the Male gDNA Standard as indicated in Table 1. Vortex each dilution for ~10 seconds prior to removing an aliquot for the next dilution. Dispose pipette tips between dilutions.

<table>
<thead>
<tr>
<th>DNA Concentration (ng/µL)</th>
<th>Volume of PowerQuant™ Male gDNA Standard</th>
<th>Volume of PowerQuant Dilution Buffer</th>
</tr>
</thead>
<tbody>
<tr>

<td>48 µL</td>
</tr>
</tbody>
</table>

5. These serially diluted DNA standards are valid for 1 week when stored at 4°C.

D. **Worksheet and Reaction Setup**

1. Setup can be performed manually, with the Nimbus liquid handling robot, or a combination of both.

2. Reserve a sequential qPCR run number on the specific instrument Quant worksheet log located in the Biology Unit's network folder: G:/SupSvcsBur/Serology/2 Logs & Shared Run Wkshts/Logs YYYY.

3. The Excel workbook **DNA Worksheets** may be used to create a record of the PowerQuant 96-Well setup. A record of the setup must be included in the case's note packet. Note: If batching samples with multiple analysts, the analyst performing the quantification plate setup must add their handwritten initials to the worksheet printout.

4. Enter sample names to be quantified to the **Quant List** sheet; this in turn auto-populates the **PowerQuant Template** sheet. In the **PowerQuant Template** sheet, enter an appropriate number of samples under the **Master Mix Preparation** cell to allow the sheet to calculate the amount of water, master mix, and primer mix needed for the run. Incorporate an additional 2-5 samples into the calculations to account for volume lost during pipetting.

5. If using the DNA Worksheets workbook, select the tab labeled **PQ Export**. This sheet is auto-populated from the samples entered on the Quant List and PowerQuant Template sheets. Save this worksheet as a tab-delimited text (.txt) on the network drive using the quant naming convention, so that it can be accessed in the PCR room during 7500 setup. Re-open the .txt file on the network drive in Excel and **re-save it**. Note: The re-save step is necessary; the file will fail to import without the additional re-save step. Alternatively, sample names can be manually added to the 7500 HID software. See below for instructions on manually adding samples.

6. If the Master Mix recipe was not calculated previously during PowerQuant Template sheet setup, use Table 2 to calculate the volume of each component required to prepare reaction mix for the desired number of reactions while accounting for potential volume loss from pipetting.

<table>

</tbody>
</table>

7. Ensure the 2X Master Mix, 20X Primer/Probe/IPC Mix, and Amplification Grade Water, are thawed completely to room temperature.

8. Vortex the 2X Master Mix and 20X Primer/Probe/IPC Mix for at least 10 seconds to mix. Note: Do not centrifuge after mixing as this may cause the primers and probes to concentrate at the bottom of the tube.

9. Prepare the reaction mix in a microcentrifuge tube.

10. Vortex the reaction mix for ~10 seconds. **Do not centrifuge after mixing.**

11. Add 18 µL of reaction mix to the each assigned well of a 96-well reaction plate.

12. Ensure that master mix was dispensed into all wells that will contain samples.

13. Add 2.0 µL of each DNA standard, an amplification negative (NTC sample comprised of amplification grade water), and each DNA extract to the designated wells. DNA Standards are run in duplicate; evidence samples can be run in single reactions. Dispose of the sample pipette tip after each 2.0 µL addition; never re-use a pipette tip. More than one set of DNA standards may be run on a single plate.

14. After all samples have been added to the corresponding wells, cover the plate with strip caps or optical adhesive film and ensure that each well is sealed.

15. Place the sealed 96-well reaction plate into appropriate bucket centrifuge and centrifuge at 500 RCF for ~1 minute to ensure all reagents collect at the bottom of the wells.

16. Place the plate into the ABI 7500 instrument and ensure that the orientation of the plate is correct. Row A should be towards the back of the instrument with the notch on the 96-well plate oriented in the upper-right corner.

#### E. Configure Run Setup in Real-Time PCR System and HID Real-Time PCR Analysis Software

1. Turn on the computer associated with the 7500 Real-Time PCR System.

2. Turn on the 7500 Real-Time PCR System.

3. Open the HID Real-Time PCR Analysis Software Version 1.2.

4. Select User name **Guest** and select the **OK** button.

5. On the Home screen, select the button for **Custom Assays**.

6. From the **File** menu or menu bar, select **Open**. In the resulting dialog window, open the **PowerQuant Template** experiments folder, then select **PowerQuant Template.edt**, and **Open**.

   a. **Importing sample information into the HID software:**

      i. From the **File** menu, select **Import**. In the resulting dialog window, click **Browse** and navigate through to locate and select the exported .txt file that was previously saved; and click **Start Import**. This populates the **PowerQuant Template.edt** document with sample names. A pop-up asks to **Confirm Import Plate Setup**; select **Yes**.

   b. **To manually add samples:**

      i. Select **Plate Setup** from the setup menu in the left panel, and then navigate to the **Define Targets and Samples** tab.

      ii. Select **Add New Sample**, and enter the sample name in the provided section.

      iii. Repeat for all samples.

      iv. When all sample names have been entered, navigate to the **Assign Targets and Samples** tab. Highlight a well or multiple wells for duplicate samples, and then tick the **Assign** box adjacent to the corresponding sample name in the **Assign sample(s) to the selected wells** section. This assigns the sample a well location on the reaction plate.

      v. Repeat until all samples are assigned.
vi. If a sample was assigned to the incorrect well, select the well and uncheck the box for the sample under Assign sample(s) to the selected wells; then proceed to assign the well to the correct sample name.

7. Save the .edt template as a .eds file by selecting Save As from the File menu at the top of the screen. Save the run in the Experiments folder on the 7500 computer. Name the file with the appropriate sequential qPCR run file name. This typically is a sequential run number with a nomenclature of: "Prun [instrument] [2-digit year]-[run#] [analyst initials] [date]."

8. Select Plate Setup from the setup menu in the left panel, and navigate to the Define Targets and Samples tab.

9. Inspect the information under Define Targets to ensure that all specimen information is correctly entered, including sample name and targets.

a. Select the Assign Targets and Samples tab and check that ROX is selected as the passive reference on the lower left window.

b. Select Run Method from the setup menu in the left panel and ensure that the Thermal Cycling program information is correct. Ensure the program is set to the following parameters:
   i. Holding Stage: 98°C for 2 minutes
   ii. Cycling Stage: 39 cycles; Step 1 to 98°C for 15 seconds and Step 2 to 62°C for 35 seconds

10. Press the Start Run button. Run time is approximately 1 hour.

F. qPCR Data Analysis

1. Evaluating Standard Curves Using the HID Real-Time PCR Analysis Software
   a. Select Analysis in the left panel and highlight all wells to be analyzed in the View Plate Layout tab. Unused wells may be omitted or deselect all targets.
   b. Press the green Analyze button and Save.
   c. To display standard curves, select Standard Curve from the Analysis menu in the left panel. Display the standard curves for targets by selecting from the Target drop-down menu.
   d. The 7500 HID Real-Time PCR Analysis Software performs a linear regression to the standard dilution series data and calculates the equation for the line of best fit (the standard curve).
   e. The equation is in the form of $y = mx + b$, where $x = \log$ concentration and $y = C_T$.
      i. The $R^2$ value is a measure of the fit of the data points to the regressed line.
      ii. The slope ($m$ in the equation) is an indication of the PCR efficiency. A slope of -3.3 indicates 100% PCR efficiency (i.e., the number of copies of amplification product is doubled at each cycle).
      iii. The Y-intercept ($b$ in the equation) is defined as the $y$ value ($C_T$) when $x$ ($\log$ concentration) equals 0. Therefore, $b$ corresponds to the $C_T$ value for a sample with a concentration of 1ng/μL ($\log_{10}(1) = 0$).
      iv. In general, the standard curve for each target (autosomal, Y, and degradation) has an acceptable average slope ($m$) in the range of $-3.1$ to $-3.6$ and an acceptable $R^2$ value $>0.980$.
   f. Troubleshooting: If the slope and/or the $R^2$ values vary greatly from expectation, assess the data points of the calibration curve. If necessary, one data point may be removed from the standard curve, should the slope or $R^2$ fall outside the acceptable range.
   g. To eliminate data points from the calibration curve, first determine the standard well with the problematic data. In the View Plate Layout window, select the well of interest, right click, select Omit, highlight all
wells, and then reanalyze. Verify that the problematic data point has been removed in the **Standard Curve** tab window. Do not forget to **Save** the reanalyzed data.

h. If a standard is removed from the curve, note it on the printed PowerQuant Template sheet that is maintained with the examiner's case notes.

i. If the slope and/or the $R^2$ values for the human assay remain outside the range established above after removal of a standard point, the run may need to be repeated. To avoid this, more than one set of DNA standards may be added to a plate.

j. Although the PowerQuant Kit is capable of determining human, male DNA, and degradation in a sample, determining the quantity of DNA in an unknown sample for purposes of amplification is typically based on the human assay. The male assay typically offers a means of determining the presence or absence of male DNA for screening purposes and for determining ratios of male DNA to human DNA in unknown DNA mixture samples. Should the slope and/or the $R^2$ values of the male and degradation curve fall outside acceptable ranges, the human quantification values may still be used to estimate the amount of human DNA present.

k. If the Y-Intercept varies greatly from expectation, assess the slope, $R^2$, and data points along the calibration curve. Under ideal amplification conditions, a $C_T$ value of approximately 25-26 is the ideal Y-intercept for the human standard curve; 25.5-26.5 for the male standard curve; and 26-27 for the large autosomal (degradation) standard curve. The Y-Intercept represents the $C_T$ value at the log concentration of 1 or 1ng. The Y-Intercept value may differ due to variations that are inherent with the assay. When the Y-Intercept ($C_T$ value) values are substantially greater than or less than the ideal values, the examiner should evaluate the values of the calibration curve and assess the potential problem. The plate may need to be repeated to ensure a more accurate quantification estimation, particularly when other parameters of the standard curve are not met. The examiner may also choose to adjust the quantification results to account/compensate for the potential over- or underestimation that results from a substantial shift in the Y-Intercept.

l. Verify that the Amplification Negative Control shows no demonstrable DNA signal. If signal is present in only one NTC, data from the run may still be used. If there is a signal present in both NTCs, the reaction plate must be re-run. Consult with the DNA Technical Leader or Supervisor for ways to troubleshoot the issue.

2. **Exporting Analyzed Data from the HID Real-Time PCR Analysis Software**

   a. Highlight all wells with data to export in the plate map.

   b. Select the tab to **View Well Table**; click **Group By** to view the drop-down menu; and select **Well Position (Column)**.

   c. Select **Export** from the toolbar.

   d. In the Export Properties tab of the Export Data window, select the following:

      i. Choose **Results** in the Select data to export section.

      ii. Choose **One File** from the Select one file or separate files drop-down menu.

      iii. Specify an appropriate export file name (e.g., BYY-NNN Results).

      iv. Choose **.xls** as the File Type.

      v. Use the Browse button to select a file location (e.g., on the network drive or flash drive).

      vi. Select **Start Export**.

3. **Exporting Results to the DNA Worksheets**

   a. Open the exported project .xls file in Excel. Copy all the data starting from cell A8 including the headers and paste it into cell A1 of the **PQ Results** sheet of the corresponding DNA Worksheets workbook. The data is summarized across each column, including [Human], [Y], Male: Total, Female: Male, [Degradation], [Human]/[Degradation], and IPC values.

4. **Internal PCR Control.** The IPC can be used to evaluate overall performance of a PowerQuant amplification reaction or detect PCR inhibitors in the DNA sample.

   a. If a sample yields no detectable amplification for the autosomal, Y, and degradation targets, but has an IPC amplification curve that crossed the amplification threshold without an IPC shift greater than 2 cycles, then this signifies there was insufficient DNA template in the sample for an amplification reaction.
b. If a sample has an IPC Shift value greater than 2 cycles or is undetermined, regardless of detectable amplification for the autosomal, Y and degradation quantification targets, then this indicates that a PCR inhibitor may be present in the amplification reaction. The PQ Results table shows the average CT value of the standards and the highest CT of any sample.

5. **[Auto]/[Y] Ratio:** This ratio can be used to evaluate whether a sample includes a male/female DNA mixture. The [Auto]/[Y] calculations from the DNA Worksheets workbook can be interpreted as follows:
   a. If a sample has no value for the [Auto]/[Y] ratio, then no male DNA was detected.
   b. If a sample has an [Auto]/[Y] ratio less than 2.0, then the sample may contain male DNA only or low levels of female DNA.
   c. If a sample has an [Auto]/[Y] ratio greater than or equal to 2.0, then the sample contains a possible mixture of male and female DNA.

6. **[Auto]/[D] Ratio:** This ratio can be used to evaluate whether a DNA sample is degraded. The [Auto]/[D] calculations from the DNA Worksheets workbook may be interpreted as follows:
   a. If a sample has an [Auto]/[D] ratio less than 6.0, then the DNA in the sample is likely not degraded, regardless of the value in the IPC Shift column.
   b. If a sample has an [Auto]/[D] ratio greater than or equal to 6.0 then the DNA in the sample is likely degraded but the sample does not contain PCR inhibitors. Samples with an “undetermined” [Auto]/[D] ratio are severely degraded.
   c. If a sample has an [Auto]/[D] ratio greater than 6.0 and an IPC Shift value greater than 2 cycles, then this sample likely contains PCR inhibitors and may or may not contain degraded DNA.

G. **Requirements for Quantification and Amplification:**

1. Quantification of reagent blanks (RB) is not required. However, at least one RB is typically quantified with the evidence sample set. If more than one RB is quantified, the RB demonstrating the greatest signal must be carried forward to amplification. If none of the samples in the quantified evidence set move forward for amplification, at least one RB must have been quantified or one RB must be amplified (if that RB skipped quantification).

2. When a sample does not forward to amplification, the justification for terminating analysis at quantification must be documented. Samples may not move forward to amplification for various reasons, such as:
   a. Low quantity of Human DNA or Male DNA detected in the sample
      i. Any sample may be stopped after quantification if it contain less than ~16pg of total DNA or male DNA.
      ii. Samples anticipated to contain the DNA from more than one donor may be stopped after quantification if the samples contain less than ~100pg of total DNA (e.g., touch DNA samples).
      iii. The analyst can decide to move samples forward to the amplification step, even if those samples contain a quantity of DNA less than the suggested thresholds.
   b. There is another potentially probative sample representing the same item that exhibits better quantity and/or quality for amplification.
   c. When male DNA is detected in the presence of a high quantity of Human DNA ([Auto]/[Y] ratio >50. The sample may be better suited for male-specific (Y-STR) testing.
   d. Poor quality (inhibited) or compromised DNA (severely degraded) is indicated and other methods could be employed to improve the quality. The sample may be better suited and preserved for another technology, such as Minifiler.
   e. Requested work was cancelled.

3. **Y-Screening Reporting Statements:** The following statements, or similar, are to be used when Y-screening is performed and samples are stopped after quantification.
   a. *Samples with male DNA > 16 pg and AUTO/Y < 50, however no autosomal STR analysis performed:* “Male DNA was detected in the following sample; however, this item was not selected for further testing at this time.”
   b. *Samples with male DNA < 16 pg:* “Due to an insufficient amount of male DNA, this item was not selected for further testing at this time.”
   c. *Samples with male DNA > 16 pg and AUTO/Y > 50:* “Due to an insufficient amount of male DNA compared to the amount of total human DNA, this item was not selected for further testing at this time.”
This sample may be better suited for Y-STR testing”

d. *No male DNA detected:* “Male DNA was not detected in the following sample. This sample was not processed further.”

B. HID Real-Time PCR Analysis Software Version 1.2 User Guide (P/N MAN0009819 Rev. C.0)

END OF DOCUMENT
I. Materials:

1. DNA extracts
2. DNA free 2.0 mL microcentrifuge tubes
3. Pipettes (10 µl, 20 µl, 100 µl, 200 µl, 1000 µl)
4. Pipette tips, barrier filtered
5. Concentration device (e.g. Microcon) / centrifuge
6. Evaporative centrifuge
7. TE-4 buffer
8. Sterile water

II. Protocols: Preparing samples for amplification may be as simple as diluting a DNA extract in order to adjust for total DNA mass and volume input, or it may involve reducing the volume of DNA extract to concentrate DNA to a desired quantity required for amplification. The protocols discussed below may be used individually or in combination to achieve the most desirable balance of conditions to accomplish quality amplification. For any technique or combination of techniques, the paired reagent (extraction) blank from the sample set must be treated in the same fashion as the evidence sample set. For example it must contain the same reagent components, and if concentrated, it must be concentrated to the same level as the evidence sample in the set with the greatest concentrated volume.

1. Dilution of samples:

   a. Each PCR amplification protocol requires a set total volume. The protocol sets a range of total input DNA as the template to achieve optimal PCR product. Samples that possess DNA concentrations exceeding the optimal input for PCR amplification need to be diluted.

   b. Procedure: Using a portion of the DNA extract, adjust the concentration using TE−4 to meet the target input. This can be accomplished similar to the following example:

      1. Required template volume input: 15 µl
      2. Optimal total DNA template: 1.0 ng
      3. Starting Sample Concentration: 10 ng/µl
      4. Required optimal PCR input concentration: 1.0 ng / 15 µl = 0.0667 ng/µl
      5. Formula to adjust Starting Concentration to Optimal Concentration:

         \[
         \frac{\text{Starting Sample Concentration}}{\text{Optimal Concentration}} = \text{Dilution Factor}
         \]

         \[
         \frac{10 \text{ ng/µl}}{0.0667 \text{ ng/µl}} = 150
         \]

         Therefore, dilute an aliquot of the starting extract 150 fold (1:150 DNA extract: TE-4 and 15uL will be used for amplification)

2. Concentration of samples:

   a. Samples that have volume greater than the required input volume but a concentration less than the optimal template concentration can be concentrated.

   b. The amount of concentration can be calculated similar to the following example:

      1. Required template volume input: 15 µl
      2. Optimal total DNA template: 1.0 ng
      3. Starting Sample Concentration: 0.05 ng/µl

      Formula to adjust Starting Concentration to Optimal Concentration:

      \[
      \frac{\text{Starting Sample Concentration}}{\text{Optimal Concentration}} = \text{Concentration Factor}
      \]

      \[
      \frac{0.05 \text{ ng/µl}}{0.0667 \text{ ng/µl}} = 0.75
      \]

      Therefore, concentrate an aliquot of the starting extract 0.75 fold (1:0.75 DNA extract: TE-4 and 15uL will be used for amplification)
4. Formula to adjust Starting Concentration to Optimal Concentration:

\[
\text{ng/0.05 ng/\mu L} = 20 \text{ uL of extract concentrated to 15uL}
\]

c. **Evaporative Centrifuge**

**Procedure:**

1. Turn on the evaporative centrifuge.
2. Select the samples requiring concentration and their corresponding reagent (extraction) blank(s). Transfer the desired amount of extract from each sample to separate amplification tubes. (Note: the paired reagent (extraction) blank must be concentrated to the same concentration volume as the sample with the highest concentrated volume in the sample set.) Place tubes (uncapped) into the centrifuge in an orientation to ensure that the weight is balanced throughout the rotor.
3. Close the centrifuge lid and make sure switch “D” is set to “High.”
5. Optional: Set the timer to allow for appropriate spin time (on average 1.5uL per minute is the evaporative rate).
7. Remove tubes and measure volumes.
8. Evaluate the volume of extracts. If volume is still substantially higher than desired, repeat evaporative steps; if the volume has been reduced to less than the desired volume, replenish volume using TE-4. If the sample has evaporated to dryness, reconstitute with the desired volume of TE-4 and heat the sample for 10 minutes at 56°C to dissolve DNA that may have precipitated onto the tube walls.

d. **Concentration devices** (such as a Microcon concentrator): Samples that need buffer exchange in addition to concentration should be concentrated through a concentration device. (Note: some DNA can be expected to be lost through this transfer device, so the analyst should use their best judgment in assessing the potential benefit of concentration versus the loss of DNA template).

**Procedure:**

1. Fill a labeled concentration device with a sufficient volume of TE-4 so that the sum of the DNA extract plus the TE-4 totals a volume of 500 µL. (Note: a paired reagent (extraction) blank must be treated similarly and concentrated to the same level as the evidence sample in the set with the greatest volume being concentrated.) For low level DNA samples, 1 μg of carrier RNA may be added to the concentration device prior to the addition of the extract: Add 1uL of reconstituted stock carrier RNA to 1 mL sterile water. Add 100 uL of the cRNA dilution to the microcon filter to pre-soak the filter prior to the addition of the extract.
2. Spin the concentration device down to dryness, typically 10-18 minutes at 14,000 RPM.
3. Add TE-4 to the membrane. The volume added is dependent on the volume needed for subsequent quantification and amplification(s).
4. Invert the concentration device chamber into a collection cup or tube and collect the concentrated DNA by spinning the concentration device at 4,000 RPM for typically 3-5 minutes.
5. If the volume is less than the required input volume for the PCR procedure the analyst may add TE-4 directly to the sample retentate to bring the volume up to the desired amount. (Note: At least 17 μL is needed for subsequent quantification and amplification.) Alternatively, TE-4 can be re-added to the membrane of the concentration device, inverted and spun down again to collect the volume and any residual DNA potentially remaining on the membrane.

3. **Overcoming inhibition:**

Many inhibitors of the Taq polymerase have been identified. Inhibitors routinely encountered in forensic casework include heme, clothing dyes, tannic acid, and humic acid. General pre-amplification schemes that have been used successfully to reduce inhibition are as follows:

a. Robotic Extraction Method:
The Qiagen Investigator kit/EZ-1 robot is an effective extraction method at removing inhibitors. The EZ-1 robot uses multiple washes while the DNA absorbs onto silica beads.

b. **Dilution Method:**

Reducing the inhibitor by diluting the sample is another effective technique, when sufficient DNA template is present. This process works for a range of approximately 5-10 fold dilutions of the DNA extract. Several amplifications may need to be attempted to bracket the proper balance of DNA template while reducing the inhibitor.

c. **Freeze-thaw method:**

When visible inhibitors (such as fabric dye) have co-extracted with the sample, the freeze-thaw method can be used to help overcome the inhibitor or reduce the amount of inhibitor. Many inhibitors can be partially precipitated within the DNA extract due to the solubility and density differences of the DNA relative to the inhibitor, particularly at low temperatures.

**Procedure:**

1. Freeze the DNA extract.
2. Remove the extract from the freezer and immediately centrifuge the tube at high speed 2-3 minutes.
3. Refreeze the extract without disturbing the pellet.
4. Repeat 2-4 more times. The freeze-thaw method will pellet/concentrate the inhibitor/dye to the bottom of the microcentrifuge tube due to the inhibitor's higher density.
5. Without disturbing the dye pellet, pipette/transfer the top portion of the extract to a new tube.
6. Retain the original tube containing the concentrated/ pelleted inhibitor.

END OF DOCUMENT
Amplification of Evidence Samples Using the PowerPlex® Fusion 6C System.

A. Introduction

1. The PowerPlex® Fusion 6C System is a 27-locus multiplex for human identification applications including forensic analysis, relationship testing and research use. This six-color system allows co-amplification and fluorescent detection of the 20 autosomal loci in the expanded CODIS core loci (CSF1PO, FGA, TH01, TPOX, vWA, D1S1656, D2S1338, D2S441, D3S1358, D5S818, D7S820, D8S1179, D10S1248, D12S391, D13S317, D16S519, D19S433, D21S11 and D22S1045) as well as Amelogenin and DYS391 for gender determination. The Penta D, Penta E, and SE33 loci are also included to increase discrimination and allow searching of databases that include profiles with these loci. Finally, two rapidly mutating Y-STR loci, DY5S70 and DY5S76, are included in the multiplex. This extended panel of STR markers is intended to satisfy both CODIS and ESS recommendations.

2. The PowerPlex® Fusion 6C System is compatible with the Applied Biosystems® 3500 and 3500xL Genetic Analyzers with Data Collection Software and the DC 6-Dye Module v1 License (Life Technologies).

B. Materials

1. Applied Biosystems ProFlex Thermal Cycler
2. The PowerPlex® Fusion 6C System is compatible with the Applied Biosystems® 3500 and 3500xL Genetic Analyzers with Data Collection Software and the DC 6-Dye Module v1 License (Life Technologies).

C. Controls and Samples

1. Reagent Blank Controls: At least one extraction (reagent) blank (RB) associated with the evidence extraction set must be amplified. The RB must be amplified under the same conditions as the evidence set (using the same amplification kit/primer set and using the same model thermal cycler). The RB must be concentrated in volume similar to the most concentrated in volume evidence sample.
   a. If an evidence sample is re-amplified at a higher target DNA amount than the original amplification, then the reagent blank must also be re-amplified under the different amplification volume conditions. If the evidence sample is re-amplified under the same conditions (volume and target DNA amount), re-amplification of the reagent blank is not necessary. QAS 9.5.3.2.

2. Amplification Controls: A positive and negative amplification control must be amplified concurrently with the evidence extraction set on the same thermal cycler instrument and with the same amplification kit (primers). QAS 9.5.2.
   a. If re-amplification of any sample is necessary, both positive and negative amplification controls are required.
   b. Number of samples x 1.2mm Manual Punch

D. Procedure for Amplification of Extracted DNA in a 25µL Reaction Volume Using the PowerPlex® Fusion 6C System

1. Reserve a sequential amplification run number from the amplification run log located on the Biology unit’s network folder: G:\Lab\Serology\Logs\Amp Log.
2. Turn on the ProFlex Thermal Cycler at least 15 minutes prior to running the amplification protocol.
3. Allow pre-amplification components to thaw, if frozen. Briefly spin down PowerPlex® Fusion 6C 5X Master Mix, PowerPlex® Fusion 6C 5X Primer Pair Mix, and 2800M Control DNA 10ng/µL. The optimal level of input DNA for each sample is 0.5-1.0µg per amplification. Resolution of mixtures of two or more sources of DNA may require input levels toward the higher end, such as 1.0ng to fully detect each donor. In cases of degraded DNA, excess template DNA addition (>1.0ng) may result in a successful amplification. Also bracketing the DNA input with a series of higher amounts of DNA may result in successful amplification of different loci and combining the loci to build a composite profile.
4. Obtain a 96-well plate and label it with the amplification run number or place the needed number of 0.2mL PCR tubes (thin wall tubes) into a rack and label each tube with the amplification run number and tube number. The tube number must correspond with the sample order listed on the DNA amplification worksheet. Be sure to include positive (2800M Control DNA) and negative amplification control tubes.
5. Prepare the PCR amplification mix by adding the following volumes of reagents to a microcentrifuge tube (prepared in a PCR prep hood):
   a. Number of samples x 5.0µL of PowerPlex® Fusion 6C 5X Master Mix
   b. Number of samples x 5.0µL of PowerPlex® Fusion 5X Primer Pair Mix
6. An additional 1-2 reactions may be added to account for normal volume loss during pipetting. The DNA amplification worksheet automatically incorporates the extra reactions needed to adjust for pipette loss.
7. Vortex the PCR amplification mix for approximately 5-10 seconds. Do not spin down after vortexing.
Infrequently, a complete profile will not be obtained using the direct amplification method. In these instances, those samples can either be re-amplified using the direct method or maybe extracted.

This procedure is to be used with buccal swabs and bloodstained FTA cards only, all other reference samples must be extracted, quantified, and amplified using the amplification procedure above.

### Thermal Cycling
Place each amplification tube into the ProFlex Thermal Cycler using the 0.2mL tube thermal cycle spacer and begin the thermal cycling process. Select “Set-up Run” on the center of the main screen, followed by “Open Method” on the next screen. Select “Fusion 6C” from the menu of methods to view the cycling parameters. Select “Verify Block” on the right bottom and finally, “Start Run” on the following screen. Total final time is approximately 1 hour.

#### Thermal Cycler Parameters

<table>
<thead>
<tr>
<th>Cycle Description</th>
<th>Temperature</th>
<th>Time</th>
<th>Number of Cycle(s)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Initial Incubation</td>
<td>96°C</td>

</tr>
</tbody>
</table>

3. At the completion of the thermal cycling process, remove the amplified samples and proceed either to fragment analysis on a capillary electrophoresis system (see Bio. 2. DNA.09) or temporarily store the amplified products protected from light at approximately 4°C. Amplified samples being stored long-term (i.e., greater than 1 week) should be stored at -20°C.

### Direct Amplification of Reference Samples Using the PowerPlex® Fusion 6C System

This procedure fails to be used with buccal swabs and bloodstained FTA cards only, all other reference samples must be extracted, quantified, and amplified using the amplification procedure above. Infrequently, a complete profile will not be obtained using the direct amplification method. In those instances, those samples can either be re-amplified using the direct method or maybe extracted, quantified, and amplified using the amplification procedure above.

#### PCR Setup

1. Reserve a sequential amplification run number from the amplification run log located on the Biology unit's network folder: G:\Lab\Serology\Logs\Amp Log.
2. Turn on the ProFlex Thermal Cycler at least 15 minutes prior to running the amplification protocol.
3. Allow pre-amplification components to thaw, if frozen. Briefly spin down PowerPlex® Fusion 6C 5X Master Mix, PowerPlex® Fusion 6C 5X Primer Pair Mix, 2800 Control DNA and Water, Amplification Grade to bring the contents to the bottom of the tube. If performing a direct amp from FTA cards, spin down the tube of 5X AmpSolution reagent as well.

#### Swab Preparation

1. Swab Preprocessing
   a. Place a half or whole buccal swab head in a 2.0mL microcentrifuge tube.
   b. Add 0.0mL of SwabSolution Reagent to each tube if using a whole swab, add a volume of SwabSolution reagent between 0.5mL and 1.0mL to each tube if using 1/2 a swab.
   c. Place each tube in a heat block and incubate at 70°C for ~30 minutes. Note: Buccal swab extracts can be stored at ~4°C for up to 24 months.
2. Prepare the PCR amplification mix for all buccal swab samples by adding the following volumes of reagents to a microcentrifuge tube (prepared in a PCR prep hood):
   a. Number of samples x 5.0µL of Water, Amplification Grade
   b. Number of samples x 2.5µL of PowerPlex® Fusion 6C 5X Master Mix
   c. Number of samples x 2.5µL of PowerPlex® Fusion 5X Primer Mix
   d. Number of samples x 2.5µL of 5X AmpSolution Reagent

#### Swab Punch Preparation

1. Ensure the puncher is free of contamination by either bleaching and thoroughly drying the puncher or performing punches on a blank portion or blank FTA card before using.
2. Using a manual 1.2mm puncher, take one 1.2mm punch from the bloodstain on a FTA card and directly eject it into a labeled 0.2mL PCR tube.
3. Prepare the PCR amplification mix for all Punch samples by adding the following volumes of reagents to a microcentrifuge tube (prepared in a PCR prep hood):
   a. Number of samples x 5.0µL of Water, Amplification Grade
   b. Number of samples x 2.5µL of PowerPlex® Fusion 6C 5X Master Mix
   c. Number of samples x 2.5µL of PowerPlex® Fusion 6C 5X Primer Mix
   d. Number of samples x 2.5µL of 5X AmpSolution Reagent

#### Thermal Cycling

Place each amplification tube into the ProFlex Thermal Cycler using the 0.2mL tube thermal cycle spacer and begin the thermal cycling process. Select “Set-up Run” on the center of the main screen, followed by “Open Method” on the next screen. Select “Fusion 6C” from the menu of methods to view the cycling parameters. Select “Verify Block” on the right bottom and finally, “Start Run” on the following screen. Total final time is approximately 1 hour.

<table>
<thead>
<tr>
<th>Cycle Description</th>
<th>Temperature</th>
<th>Time</th>
<th>Number of Cycle(s)</th>
</tr>
</thead>
<tbody>
<tr>

</tbody>
</table>

3. At the completion of the thermal cycling process, remove the amplified samples and proceed either to fragment analysis on a capillary electrophoresis system (see Bio. 2. DNA.09) or temporarily store the amplified products protected from light at approximately 4°C. Amplified samples being stored long-term (i.e., greater than 1 week) should be stored at -20°C.
6. Prepare a positive and negative amplification control.
   1. For the positive control, add 1.0µL of 2800 Control DNA (10ng/µL) to a labeled tube containing PCR amplification mix.
   2. For the negative control, just add the amplification reagents to a PCR tube.

D. If preparing a direct amplification for both swabs and FTA punches, prepare one positive control using the swab preparation and two negative amplification controls, one for each of the preparations.

E. Thermal Cycling: Briefly shake or spin down the tubes to bring the contents to the bottom. Ensure that each amplicon has a pink/purple color and that they all contain approximately the same volume of liquid before placing them on the thermal cycler. Place all prepared amplification sample tubes into the ProFlex Thermal Cycler using the 0.2mL tube thermal cycle spacer and begin the thermal cycling process. Select “Set-up Run” on the center of the main screen, followed by “Open Method” on the next screen. Select “Fusion 6C Direct Amp” from the menu of methods to view the cycling parameters. Select “Verify Block” on the bottom right and finally, “Start Run” on the following screen. Total cycling time is approximately 50 minutes.

   1. Thermal Cycler Parameters: The following thermal cycling parameters are used for the direct amplification of the PowerPlex® Fusion 6C loci on ProFlex PCR Systems. The parameters are pre-set under file name “Fusion 6C Direct Amp” under “Methods”.

</tbody>
</table>

   At the completion of the thermal cycling process, remove the amplified samples and proceed either to fragment analysis on a capillary electrophoresis system (see Bio.2.DNA.09) or store temporarily store the tubes protected from light at approximately 4ºC. Amplified samples being stored long-term (greater than 1 week) should be stored at -20ºC.

IV. References

A. PowerPlex® Fusion 6C System Technical Manual (TMD045 Rev. 10/15)
B. ProFlex™ PCR System User Guide Installation, Use, and Maintenance User Guide (P/N MAN0007697 Rev. A.0)

V. Amplification of Extracted DNA Samples Using the PowerPlex® Y23 System.

A. Introduction

B. Materials

   1. Applied Biosystems ProFlex Thermal Cycler
   2. Promega PowerPlex Y23 System, consisting of:
      - Pre-amplification Components
        - PowerPlex® Y23 5X Master Mix
        - PowerPlex® Y23 10X Primer Pair Mix
        - 2800M Control DNA 10ng/µL
      - Water, Amplification Grade
      - Post-amplification Components
        - PowerPlex® Y23 Allelic Ladder Mix
        - WEN Internal Lane Standard 500 Y23

   3. Storage Conditions: Upon receipt, store all components, except the 2800M Control DNA at -30ºC to -10ºC in a nonfrost-free freezer. Store the 2800M Control DNA at 2–10°C. Make sure that the 2800M Control DNA is stored at 2–10°C for at least 24 hours before use. After the first thaw, store the PowerPlex® Y23 System components at 2–10°C, where they are stable for 1 year. Do not refreeze. The PowerPlex® Y23 5X Primer Pair Mix, PowerPlex® Y23 Allelic Ladder Mix and WEN Internal Lane Standard 500 (WEN ILS 500 Y23) are light-sensitive and must be stored in the dark. When in use, limit exposure to light.

C. Controls and Samples

   1. Reagent Blank Controls: At least one extraction (reagent) blank (RB) associated with the evidence extraction set must be amplified. The RB must be amplified under the same conditions as the evidence set (using the same amplification kit /primer set and using the same model thermal cycler). The RB must be concentrated in volume similar to the most concentrated in volume evidence sample. The 2800M Control DNA must also be re-amplified under the same amplification volume conditions. If the evidence sample is re-amplified under the same conditions (volume and target DNA amount), re-amplification of the reagent blank is not necessary. QAS 9.5.3.2

   2. Amplification Controls: A positive and negative amplification control must be amplified concurrently with the evidence extraction set on the same thermal cycler instrument and with the same amplification kit (primers). QAS 9.5.2.

   3. DNA Samples: Evidence samples are quantified prior to amplification, see Human DNA Quantification Bio.2.DNA.06. Prior to amplification, samples with high concentrations of DNA may need to be diluted and samples with low concentrations of DNA may need to be concentrated. Refer to Bio.2.DNA.07 "Preparing Extracts for PCR Amplification" for additional information.

   D. DNA Target Amount: During validation, full profiles were detected consistently at 0.125ng and above from single source samples, full profiles were also observed in "some" samples with as low as 0.064ng of DNA. The optimal level of input DNA is 0.125ng - 0.25ng per amplification for single source samples and 0.250ng - 0.5ng for samples anticipated to be mixtures of male DNA. In cases of degraded DNA or samples that have an excessive amount of female DNA that may inhibit results, excess template DNA addition (~0.25ng) may result in a successful amplification.

   E. PowerPlex® Y23 System Sample Preparation

   1. Reserve a sequential amplification run number from the amplification run log located on the Biology unit's network folder.
   2. Turn on the ProFlex Thermal Cycler at least 15 minutes prior to running the amplification protocol.
   3. Allow pre-amplification components to thaw, if frozen. Briefly spin down PowerPlex® Y23 5X Master Mix, PowerPlex® Y23 10X Primer Pair Mix, 2800M Control DNA and Water, Amplification Grade to bring the contents to the bottom of the tube. Gently vortex each reagent for approximately 15 seconds before each use. (NOTE: In order to avoid creating a concentration gradient, do not centrifuge the primer and master mix after vortexing.)
   4. Samples will be amplified in a 96-well plate. The amplification run number should be written on the side of the plate. Be sure to include positive (2800M Control DNA) and negative amplification controls.
   5. Prepare the PCR amplification mix by adding the following volumes of reagents to a microcentrifuge or screw cap tube (prepared in a PCR prep hood):
      - Number of samples x 5.0µL of PowerPlex® Y23 5X Master Mix
b. Number of samples x 2.5µL of PowerPlex® Y23 10X Primer Pair Mix
c. Number of samples x 2.5µL of Water, Amplification Grade

6. An additional 1-2 reactions may be added to account for normal volume loss during pipetting. The DNA amplification worksheet automatically incorporates the extra reactions needed to adjust for pipette loss.

7. Vortex the PCR amplification mix for approximately 5-10 seconds. Do not spin down after vortexing.

8. Aliquot 10µL of PCR amplification mix into each plate well.

9. Vortex and briefly spin down the DNA extracts, if not already done so. DNA extracts at this stage have been either diluted, concentrated or are prepared in a volume necessary for amplification. Verify that the extract tubes are prepared and are in the correct order as specified in the amplification worksheet. One at a time, open the DNA extract tube and locate the corresponding well on the plate. Add up to 15µL of the DNA extract to the appropriate well. If adding less than 15µL, the remaining volume is made up using water, amplification grade for a total of 25µL.

10. Visually verify the entire DNA extract volume is expelled into the PCR amplification mix reagent. Recap both tubes. Continue similarly with the remaining extracts, handling one set of tubes at a time.

11. Prepare a positive and negative amplification control.
   a. For the positive control, vortex the pre-thawed tube of 2800M Control DNA and dilute an aliquot of 2800 Control DNA (10ng/µL) to target 0.200 ng of the positive control DNA. Dilute using the Amplification Grade Water. Add 15µL of a 1:750 dilution for a 0.200 ng input. Prepare a fresh DNA dilution for each set of amplifications.
   b. For the negative control, add 15µL of Amplification Grade Water.

12. Cover the plate. Optional: Briefly centrifuge the plate to bring contents to the bottom of the wells and remove any air bubbles. Ensure that each amplicon has a pink/purple color and that they all contain approximately the same volume of liquid before placing them on the thermal cycler.

F. Thermal Cycling: Place the 96 well plate into the ProFlex Thermal Cycler and begin the thermal cycling process. Select “Set-up Run” on the center of the main screen, followed by “Open Method” on the next screen. Select “Promega Y23” from the menu of methods to view the cycling parameters. Select “Verify Block” on the bottom right and finally, “Start Run” on the following screen. Total cycling time is approximately 1 hour 26 minutes.

1. Thermal Cycle Parameters: The following thermal cycling parameters are used to amplify the PowerPlex® Y23 kit on ProFlex PCR Systems. The parameters are pre-set under file name “Promega Y23” under “Methods”.

2. At the completion of the thermal cycling process, remove the amplified samples and proceed either to fragment analysis on a capillary electrophoresis system (see Bio.2.DNA.09) or temporarily
I. Capillary Electrophoresis Protocol Using the AB 3500 Genetic Analyzer

A. Materials

1. Applied Biosystems 3500 Genetic Analyzer
   - Dell computer with 3500 Series Data Collection Software 3, ver. 3.1 or ver. 4.0
   - 3500 Capillary Array (8 cap. 36cm uncoated, P/N 4404683)
   - Anode Buffer Container, 3500 Series (P/N 4393927)
   - Cathode Buffer Container, 3500 Series (P/N 4408256)
   - POP-4 Polymer for 3500/3500XL Genetic Analyzers (P/N 4393710, 4393715)
   - Ultra-pure, deionized (Hi-Di) formamide (P/N 4440753)
   - Conditioning Reagent, 3500 Series (P/N 4393718)
   - Promega WEN Internal Lane Standard 500
   - Promega PowerPlex Fusion 6C Allelic Ladder Mix
   - Promega PowerPlex 6C Matrix Standard
   - Promega WEN Internal Lane Standard 500 Y23
   - Promega PowerPlex Y23 Allelic Ladder Mix
   - Promega PowerPlex 5C Matrix Standard
   - 96-well reaction plates with septa
   - 96-well plate retainer assembly
   - Cathode buffer container septa
   - Microcentrifuge
   - Bucket centrifuge
   - Eppendorf ThermoStat C
   - Electronic Ice block
   - Pipettes with barrier filtered tips

II. Preparing the PCR-STR Product for Analysis on the AB 3500

Preparing amplified samples for analysis on the AB 3500 capillary electrophoresis (CE) unit involves diluting a portion of the PCR product in a mixture of Hi-Di formamide and WEN Internal Lane Standard (ILS) 500 or 500 Y23, followed by additional steps to keep the PCR product denatured.

A. Reserve a sequential CE run number from the CE run log located on the Biology unit's network folder: G/SupSvcsBur/LAB/Serology/Logs & Shared Run Wkshts.

B. Before preparing a plate for analysis, fill out the 3500 Worksheet tab of the Excel DNA Worksheet. Print a copy of the worksheet to assist with sample setup and as a record in the PCR room run binder. Samples can either be manually typed into the software's plate setup or imported electronically from a tab delimited document created from the 3500 Worksheet. Note: When batching samples with multiple analysts, the individual that performs the plate setup must initial the worksheet by hand.

C. Turn on the electronic ice block and ThermoStat C. Press the 95°C preset button on the Thermostat C and allow it to come to temperature.

D. Remove a previously aliquoted tube of Hi-Di formamide from the freezer to thaw. Note: Multiple freeze-thaw cycles or long-term storage at 4°C may cause breakdown of formamide. Use PPE when handling formamide; formamide is a teratogen and irritant.

E. Allow post-amplification components to thaw if frozen. If setting up samples amplified using Fusion 6C briefly spin down tubes of WEN ILS 500 and PowerPlex Fusion 6C Allelic Ladder Mix. If setting up samples amplified using Y23 briefly spin down tubes of WEN ILS 500 Y23 and PowerPlex Y23 Allelic Ladder Mix. Vortex each reagent for ~5-10 seconds before each use. Do not centrifuge after vortexing so as to avoid creating a concentration gradient. Also, minimize post-amplification components’ exposure to light.
F. Prepare a master mix by combining the necessary amount of Hi-Di formamide and WEN ILS 500 or WEN ILS 500 Y23 in a microcentrifuge or screw cap tube in the following proportion:

1. Number of samples x 9.5 µL Hi-Di formamide
2. Number of samples x 0.5 µL WEN ILS 500 or WEN ILS 500 Y23

Note: Include additional volume for allelic ladders and WEN ILS 500 or WEN ILS 500 Y23 blank samples and any volume loss during pipetting.

G. Vortex mixture for 5-10 seconds.

H. Label a 96-well plate with the appropriate run number.

I. Aliquot 10 µL of the master mix into each well that will contain either a PCR product, an allelic ladder, or a WEN ILS 500 or WEN ILS 500 Y23 blank. The capillary array injects from all 8 wells simultaneously, therefore, a sample or formamide blank must be present in all wells of a column in a plate. Do not allow capillaries to inject from dry wells; doing so will damage the capillary array.

J. Add 1.0 µL of PCR product or allelic ladder to the appropriate wells of the 96-well plate containing the master mix. When possible, load multiple allelic ladders in each run. The required frequency of allelic ladders is one for every 3 injections (24 samples) with a suggested minimum of two ladders per run. Vary the placement of ladders in order to utilize different capillaries of the array.

K. Cover the plate with a septa mat.

L. Briefly centrifuge the plate to remove any air bubbles and to ensure that the contents are all collected at the bottom of the wells.

M. Place the sample plate on the ThermoStat C to heat-denature at 95°C for three minutes.

N. Snap-cool the sample plate on the electronic ice block for three minutes. To prevent arcing issues, remove any moisture from the bottom of the plate with a lint-free lab wipe.

O. Place the sample plate into the plate base, then cover with the plate retainer. The cover should snap into place on both sides. Verify that the holes of the plate retainer and the septa are aligned.

P. The sample plate is now ready for analysis on the AB 3500 Genetic Analyzer.

III. Preparing the AB 3500 Genetic Analyzer System:

A. Instrument Set-up:

1. Turn on the computer and allow it to boot up completely.
2. Depress the power button on the front panel to turn on the instrument. Wait for the status indicator light on the instrument to turn solid green.
3. In the Windows login screen, select the "INSTR-ADMIN" icon (username: SUM-3500-1\Administrator) and type "INSTR-ADMIN" for the password.
4. Wait for the 3500 Server Monitor icon in the Windows notification area to completely launch, as indicated by a green check mark.
5. Double click on the 3500 icon on the desktop to launch the 3500 Series Data Collection Software. In the User Name field, type "Administrator" and in the Password field, type "Administrator1."
6. The Dashboard screen will launch.
7. On the right side of the Dashboard screen, click the "Refresh" button. Check if the consumable status is acceptable and for any maintenance notifications. Replenish consumables and perform maintenance tasks as necessary. As a maintenance task is completed, click the check mark to mark it as done. Actions are recorded in the Notifications Log.
8. Click "Start Pre-Heat" to begin pre-heating the oven and detection cell. The Oven Temperature and Detection Cell Temperature will turn green when at the proper temperature.
9. Visually check if there is sufficient buffer at or above the fill line.
10. Verify that the pump block and channels are free of bubbles. Run the Remove Bubbles Wizard from the Maintenance tab if needed.
11. Press the "Tray" button on the instrument to recall the autosampler to the front for loading. Pull down on the clip (on the left side if loading in position A, or right side if loading in position B) and place the sample plate and
retainer in the autosampler with the retainer label facing outward toward the instrument door. Release the clip when the plate assembly is seated properly in place.

12. Close the instrument door to home the autosampler and to re-initialize the instrument.

**B. Data Collection Plate Setup**

1. **Import Plate Setup**
   a. The plate sample setup can be created and imported from the 3500 Sample Worksheet. Ensure that the CE Run field of the 3500 sheet is properly filled out and save the 3500 Export sheet as a .txt (text tab delimited) file. Save the file on an accessible network drive or on a flash drive.
   b. From the Dashboard screen of the 3500 Data Collection software, click the Create New Plate button.
   c. In the following Define Plate Properties screen, click the Assign Plate Contents button near the bottom of the screen.
   d. Select the Import option on the top menu bar.
   e. Locate the file to be imported and click Open.
   f. Click OK when the plate setup has been successfully imported.
   g. Save the plate using the standard CE naming convention, DYY-XXX AA MM-DD-YY, where XXX is the sequential run number and AA is the operator's initials.

2. **Manual Plate Setup**
   a. From the Dashboard screen, click the Create New Plate button.
   b. In the Define Plate Properties screen, type in a name for the plate using the standard CE naming convention, DYY-XXX AA MM-DD-YY, where XXX is the sequential run number and AA is the operator's initials.
   c. For "Plate Type," select "HID" from the drop-down menu.
   d. Click the Assign Plate Contents button near the bottom of the screen.
   e. Proceed to populate the plate with sample names to match that of the corresponding prepared sample plate.
   f. In the bottom right of the screen, click to expand the Customize Sample Info pane.
   g. Highlight wells of interest in the plate view, and select its corresponding "Sample Type" from the drop-down menu in the Customize Sample Info pane. All wells are defaulted to "Sample," but at least one well must be designated as an "Allelic Ladder." Other sample type options include "Positive Control," "Negative Control," and "HiDi," but are not necessary in order to proceed with analysis.

   **Note:** The plate can alternatively be populated in a tabular fashion by selecting the Table View tab adjacent to the Plate View tab at the top left of the plate layout.

   h. If running samples amplified using Fusion 6C: In the "Assays" window to the bottom left of the plate layout, click Add from Library and select "HID 36_POP4_Promega_J6" if using 3500D or "HID_POP4_Promega_J6_13sInj" if using 3500E. This assay will have HID 36_POP4_1_Promega_J6 selected as the protocol and WEN_ILS_500 selected as the QC protocol.

j. In the "File Name Conventions" window just below the center of the plate layout, click "Add from Library" and select "CCC STR."

k. In the "Results Group" window to the bottom right of the plate layout, click Add from Library and select "Run."

l. Highlight wells of interest from the plate layout. Enable the checkbox adjacent to the chosen assay, file name convention, and results group to apply the selections to the samples.

m. Navigate to the Save Plate icon in the menu bar above the plate layout to save the changes to the plate.

3. Use a Plate Template

a. From the Dashboard screen, click the Create New Plate button.

b. Proceed to type a name for the plate using the CE naming convention, DYY-XXX AA MM-DD-YY, where XXX is the sequential run number and AA is the operator's initials.

c. Click on the New Plate option from the menu bar and then select Create New Plate from Template.

d. Select Promega PowerPlex Fusion 6C Plate Template or Promega PowerPlex Y23 Plate Template, and then click Open.

e. Click the Assign Plate Contents button on the bottom of the screen.

f. Proceed to populate the plate with sample names corresponding to the prepared plate.

- Highlight the populated wells and enable the checkboxes for the following:
  - "HID 36_POP4_Promega_J6" as the Assay for Fusion 6C or "HID 36_POP4_Promega_G5" for Y23.
  - "CCC STR" for File Name Conventions
iii. "Run" for Results Group

h. Navigate to the Save Plate icon in the menu bar to save the changes to the plate.

C. Link and Run a Plate

1. Click the Link Plate for Run button on the bottom of the screen to proceed to the Load Plates for Run screen. Select OK.

Note: Ensure that the plate is linked to the corresponding position on the software. Click the Switch Plates icon in the center to designate the plate to the other position as necessary.

2. Leave the Run Name to the default setting which is the date and time of the run.

3. On the bottom of the screen, click the Start Run button to proceed directly to running the plate in the defaulted plate column order with one injection for each column. Alternatively, click the Create Injection List button to go to the Preview Run Screen to specify the order of injections, add any duplicate runs or to delete injections. To modify the injection list, highlight the injection of interest from the list, and use any of the options from the menu bar above to create the desired injection order. Options include Move Up in List, Move Down in List, Delete, and Duplicate. When the injection list is finalized, click the Start Run button. Note: Navigating away from the Preview Run screen to edit plate details will clear the current injection list. Verify that the plate contents are accurate before creating an injection list.

4. The Monitor Run screen is displayed after clicking Start Run. The plate view shows the current injection highlighted in green. Each injection runs for approximately 40 minutes and the status bar shows an estimated run time. The menu bar at the top of the Monitor Run screen displays options to edit the injection order, re-inject, delete, pause, resume, and abort the run.

Note: Re-injections must be inputted before the run completes.

5. When an injection is finished running, it is flagged with a check mark icon in the "Injection" and "Analysis" columns of the injection list. The software can detect if the sequence or sample quality falls below the user-specified quality thresholds set in the protocol and displays a flag in the "Flags" column in those instances. If no samples are listed in this column, the samples have passed quality checks. If a flag is displayed, proceed to expand the “Flag” pane at the bottom right of the screen. The table will show a more specific flag identifying sample wells that may need further review.

   a. Sample quality is in suspect range and should be reviewed

   b. Indicative of offscale peaks and/or suspect sample quality

D. Review HID Analysis Results

1. Access the View Fragment/HID Results screen from either the Monitor Run screen by clicking Review Results or the Dashboard by clicking View Run Results.

2. While an instrument run is in progress, the samples table lists results for completed injections in the current run in the View Fragment/HID Results Screen.

3. Select one or more samples in the sample table to display the data in the plot view and sizing table view.

   a. Review Sample Quality: In the sample view, click the Table Settings button. Pay special attention to the following columns and flags:

      i. Offscale: A yellow indicator is present when at least one data point in the analysis range has saturated the CCD camera.

      ii. Broad Peak: A yellow indicator is present when at least one peak exceeds the broad peak threshold.

      iii. Sizing Quality: A red indicator is present when the sizing quality fails and the yellow indicator is present when sizing quality is suspect.

   b. Click a flag in the samples table, or select samples in the samples table to display the associated data in the Plot View and Sizing Table View.

E. Methods for Dealing with Saturated Data (Fusion samples only)

A. There are two methods approved for reducing the effects of saturated data: a decreased 7 second injection or diluting the amplicon in a 1:10 or 1:20 water dilution.
A. When performing a 7 second injection, the "7s_Inj_HID 36_POP4_Promega_J6" assay must be selected and applied.

B. If diluting the amplicon is preferred, prepare a 1:10 or 1:20 amplicon to water dilution and use 1.0 uL for sample setup on the 3500.
   i. Clearly label the sample as a dilution or 7 second injection on the CE run sheet and electropherogram.

F. Changing the Capillary Array
   1. The manufacturer suggests replacing a capillary array around 160 injections. (This is a conservative value and is left to operator discretion for capillary replacement.)
   2. To install a new capillary, click the Maintenance tab on the menu bar of the Collection Software. Navigate to the Wizards menu from the left navigation pane. Select the Install Capillary Array button and follow the prompts to remove the old array and install the new array. When the Install Capillary Array Wizard is complete, proceed to Spatial Calibration.

G. Spatial Calibration
   1. A spatial calibration is performed to establish a relationship between the signal emitted by each capillary and the position where the signal falls on and is detected by the CCD camera.
   2. A Spatial Calibration is performed when:
      a. A capillary array is installed or replaced.
      b. The capillary array is temporarily removed from the detection block.
      c. The detector door is opened or the detection cell is moved.
      d. The instrument is moved.
      e. A service engineer performs an optical service procedure, such as realigning or replacing the laser or CCD camera.
   3. Creating a Spatial Calibration File
      a. Access the Spatial Calibration screen through the Maintenance tab, and then select Spatial Calibration from the navigation pane.
      b. In the "Options" box, select the Fill button to fill the array with polymer before commencing the calibration. Select No Fill if the array already contains fresh polymer.
      c. Check the box for Perform QC Checks to have the software check each capillary against the specified range for spacing and signal intensity. An error message will pop up during the calibration if any of the calculations do not meet a threshold condition.
      d. Click Start Calibration.
   4. Guidelines for a passing Spatial Run:
      a. Similar peak heights
      b. A cross-hatch at the top of each peak with no misplaced crosses
      c. Single sharp peaks for each capillary; small shoulders are allowed
      d. The spacing difference between adjacent positions should be between 13 to 16 pixels in both the left spacing and right spacing columns.
   5. If the calibration passes, click Accept.
   6. If the calibration fails, select Reject and repeat the calibration. Refer to AB 3500/3500XL Genetic Analyzer User Guide for additional troubleshooting help.

H. Replenishing/Replacing Polymer
   1. POP-4 polymer for use on 3500 Series instruments comes in a ready-to-use pouch and is stable for 14 days after installation.
   2. Each pouch is rated for the stated amount of injections on the pouch. Usage is tracked by the 3500 Data Collection Software and can be easily found on the Dashboard display. Each polymer pouch includes additional volume to accommodate for volumes used during installation, running wizards, and during routine operation.
Excessive use of wizards reduces the number of remaining samples and injections based on how many times certain wizards are run.

3. If the POP-4 pouch on the instrument is expired or there is insufficient polymer to complete the run, remove a POP-4 pouch from 4ºC storage, and allow it to warm to room temperature.
   a. To change just the POP-4 pouch, click the Replenish Polymer Wizard button and follow the on-screen prompts.
   b. To wash the pump and channels and change the POP-4, navigate to the Wizards menu under the Maintenance tab and select Wash Pump and Channels. Follow the on-screen prompts to install a conditioning reagent pouch and then the POP-4 pouch. This wizard takes approximately 40 minutes to complete.

4. A pouch of POP-4 can be removed from the 3500 for storage. If removed, place a pouch cap (PN 4462785) onto the pouch, rinse the connection valve with deionized water, and then place a pouch of conditioning reagent on the connector to prevent desiccation of any residual polymer.

I. Replenishing/Replacing Buffers

1. The Anode and Cathode Buffer Containers (ABC and CBC) contain 1X running buffer to support all electrophoresis applications. The buffers are stable for 240 injections or 14 days after installation on the instrument.

2. Replace the ABC or CBC on the instrument if it is expired, past 14 days, or when buffer levels are below their fill line.
   a. Remove the buffer containers from 4ºC storage and allow them to equilibrate to room temperature.
   b. The Anode Buffer Container has a built in overflow chamber to maintain constant fluid height. Check that the plastic seal is still intact, and invert and tilt the container until the buffer is displaced to the larger reservoir. Carefully peel the plastic seal from the top.
      i. Open the instrument door and turn the container so that the RFID label faces into the instrument. Position the ABC below the pump with the anode in the larger reservoir of the container, then slide it up and back towards the instrument until it’s fixed in place.
      ii. Close the instrument door to reinitialize the system.
   c. The Cathode Buffer Container has two sides. One side contains the cathode running buffer and the other side holds the rinse fluid for the capillary. Check that the plastic seal has not been compromised before gently tilting the container back and forth to evenly distribute the buffer across the top of the baffles. Slowly peel off the plastic seal and wipe off any buffer or condensation around the container using separate lint-free lab wipes for each side.
      i. Cover the container with the appropriate septa for each side. Ensure that it is properly aligned with the holes and it is firmly seated in place.
      ii. Press the "Tray" button and allow the autosampler tray to stop in the loading position before opening the instrument door.
      iii. While using the thumb to hold up the front of the container and the forefinger to pinch the semi-circular notch on the back of the container, lower it into position on the tray. When installed correctly, the front tabs will click into place and the RFID tag faces right.
      iv. Close the instrument door to home the autosampler and reinitialize the instrument.
   d. Click the Refresh button on the Dashboard to update consumable information.

J. Spectral Calibration

1. A separate Spectral Calibration is performed when:
   a. A new dye set is used on the instrument.
   b. The polymer type is changed or the capillary array is changed.
   c. The laser or CCD camera has been realigned or replaced.
   d. The instrument has been moved.
   e. There is a noticeable decrease in spectral separation (pull-up/pull-down) in the raw or analyzed data.
   f. A service engineer performs an optical service procedure, such as realigning or replacing the laser or CCD camera.
2. Fusion 6C: The PowerPlex 6C Matrix Standard consists of DNA fragments labeled with six fluorescent dyes (FL-6C, JOE-6C, TMR-6C, CXR-6C, TOM-6C and WEN) in one tube. The spectral calibration is performed using the J6 dye set. Once generated, the spectral calibration file is applied during sample detection to calculate the spectral overlap and separate the raw fluorescent signals into individual color signals. Spectral standards are run in all eight capillaries.

3. Y23: The PowerPlex 5C Matrix Standard consists of DNA fragments labeled with five fluorescent dyes (fluorescein, JOE, TMR-ET, CXR-ET, and WEN) in one tube. The spectral calibration is performed using the G5 dye set. Once generated, the spectral calibration file is applied during sample detection to calculate the spectral overlap and separate the raw fluorescent signals into individual color signals. Spectral standards are run in all eight capillaries.

4. **Storage Conditions**: Upon receipt, store all components of the Matrix standard at –30°C to –10°C in a nonfrost-free freezer. After the first use, store the Matrix Standard components at 2–10°C. The PowerPlex® Matrix Standard is light-sensitive. Dilute the 5C or 6C Matrix Mix in the Matrix Dilution Buffer in the provided amber tube.

5. **Preparing the Spectral Calibration Chemistry**
   a. Remove the tube of 5C or 6C Matrix Mix, one tube of Matrix Dilution Buffer, and a tube of Hi-Di formamide from the freezer. Allow the reagents to equilibrate to room temperature.
   b. Vortex the Matrix Mix for ~10-15 seconds. Add 10 µL of the Matrix Mix to the tube of Matrix Dilution Buffer. Vortex the mixture for ~10-15 seconds. Label the tube with the date of dilution. This can be stored for up to 1 week at 2-10°C.
   c. Add 10 µL of the diluted 5C or 6C Matrix mixture into a tube of 500 µL of Hi-Di formamide. Vortex for ~10-15 seconds.
   d. Add 15 µL of the matrix/Hi-Di formamide mixture into all 8 wells of an entire column of a 96-well plate. Ensure the specific column is noted and selected in the spectral calibration menu later.
   e. Cover the wells with septa mat and centrifuge briefly to remove any bubbles. **Do not heat-denature.**
   f. Place the sample plate into the plate base and cover with the plate retainer.
   g. Load the plate onto the 3500 autosampler tray.

6. **Performing and Running the Spectral Calibration**
   a. Pre-heat the 3500 oven to 60°C in the **Dashboard** of the Data Collection Software. Do not start the spectral calibration run until the oven is preheated to 60°C.
   b. Navigate to the **Maintenance** tab and select **Spectral Calibration** from the left navigation pane. Under the **Calibration Run** tab, select "Matrix" under the "Chemistry Standard" drop-down menu and "Promega J6" for Fusion 6C or "Promega G5" for Y23 under the "Dye Set" drop-down menu. Specify the column that the matrix was loaded into here.
   c. Enable the checkbox for "Allow Borrowing."
   d. Click **Start Run** to begin the calibration.

7. **Evaluating the Spectral**
   a. The calibration is set up to run up to 3 injections. If all eight capillaries do not meet the Quality Value and Condition Number criteria limits in the first injection, the system moves onto a second injection. If the second injection fails, there is a third injection. If borrowing is enabled, information from a failed capillary is replaced with an adjacent passing capillary with the higher Quality Value. Only one adjacent capillary borrowing event is allowed.
   b. Passing capillaries are displayed in green and failing capillaries are displayed in red. Borrowed capillaries are displayed in yellow with an arrow indicating where borrowed results originated. Click a capillary in the table to view its spectral and raw data.
   c. If the data for all capillaries meet the criteria, click the **Accept Results** button. See the AB 3500/3500xL Genetic Analyzer User Guide for the ranges the software uses to determine if a capillary passes or fails.
   d. If any capillary data does not meet the criteria, click **Reject Results** and refer to AB 3500/3500xL Genetic Analyzer User Guide for troubleshooting help.

END OF DOCUMENT
I. Procedure for the use of GeneMapper ID-X software to analyze PowerPlex Y23 Data

A. Materials:
   1. GeneMapper ID-X v 1.5 software

B. Analyzing Data Files using GeneMapper ID-X v 1.5 Software
   1. GeneMapper-IDX (GMIDX) software is used to size DNA fragments and assign genotypes using one or more allelic ladder(s) and an internal lane standard.
   2. The data collection files must be retained on the 3500 computer until archived in the following location: C:/AppliedBiosystems/Runs/{Unique Run Folder}.
   3. Open GeneMapper ID-X and log into the software. The username is gmidx followed by your initials, then enter the password. NOTE: The computer with the Full Installation must be on to access GeneMapper ID-X from a computer with a Client Installation.
   4. Create a new project by selecting Add Samples to Project under the Edit menu, or click Add Samples to Project.
   5. In the Files tab of the Add Samples to Project window, locate the correct sample files and click Add to List. The run folder(s) should appear in the column on the right under Samples to Add. When done adding samples files, click Add on the bottom right of the window.
   6. View Raw Data and Sample Information: Click on the run folder on the left and expand the file to view the list of sample files within the folder. To view the sample info, click on a sample file. To view the raw data, click on a sample file and then click the Raw Data tab on the right. Check the raw data of each sample file to make sure the samples ran correctly on the genetic analyzer, including resolution, spikes, and baseline. To view the electrophoresis, power, and temperature (EPT) data, click on the EPT Data tab. When finished viewing, return to the main window by clicking on the run folder or the project icon.
   7. Begin the analysis in the Project window using the "CCC Fusion" Table Settings within the Samples tab of GeneMapperID-X. Remove sample files that are not needed by selecting Delete from Project under the Edit menu. Note: this move cannot be undone. Make sure that all "Sample Types" are set correctly. Allelic ladders should be set to Allelic Ladder, 2800M control should be set to Positive Control, and the negative control and reagent blanks should be set to Negative Control. All others should be assigned as a Sample.
   8. In the Project Window, apply analysis settings:
      a. Under the Analysis Method column, select "PowerPlex Y23".
      b. Click the Analysis Method column header to select the column. Under the Edit menu, select Fill Down (or use keyboard shortcut "Ctrl+D").
      c. Under the Panel column, select "PowerPlexY23_IDX_v2.0". Click the Panel column header to select the column. Under the Edit menu, select Fill Down (or use keyboard shortcut "Ctrl+D").
      d. Under the Size Standard column, select "WEN_ILS_500_IDX". Click the Size Standard column header to select the column. Under the Edit menu, select Fill Down (or use keyboard shortcut "Ctrl+D").
      e. Click the Analyze button . When prompted, name and save the project using the convention: GMX XX-XXXXX-X_AAA, where X refers to the Laboratory Case Number and AAA refers to the analyst's initials. Save the GMX project to the Security Group. The software will begin data analysis.

C. Viewing Data
   1. When analysis is completed, the software identifies any conditions that may prevent analysis or cause unexpected results. It sets a flag for the Analysis Requirements Not Met (ARNM) Process Quality Value (PQV) and displays the Analysis Requirements Summary (ARS) if a sample in the project does not meet one or more analysis requirement(s).
   2. There are three tabs available from the main screen after samples are analyzed. They are as follows: Samples, Analysis Summary and Genotypes.

D. The Analysis Summary tab:
   1. Provides a summary of the analysis status for all or a subset of samples in a project.
   2. Displays an overview of allelic ladder, control, and sample quality.
   3. Visually separates passing samples from samples that do not meet one or more quality thresholds.
   4. Allelic ladders, control samples, and samples where all thresholds are met will be listed in the "All thresholds met" column. Samples that have not met all quality thresholds will be listed in the "One or more thresholds not met" column.
GeneMapper ID-X Analysis Summary Tab

5. The samples can be displayed in each of these columns by clicking on the blue hyperlinked number within the column.

6. The hyperlink will open up a filtered samples tab. Each sample in the table will have sample-level Process Quality Value (PQV) flags as shown below:

<table>
<thead>
<tr>
<th>Acronym</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SOS</td>
<td>Sample Off-Scale</td>
<td>Indicates if any fluorescence signal within the analysis range exceeds the detection threshold of the instrument.</td>
</tr>
<tr>
<td>SQ</td>
<td>Sizing Quality</td>
<td>Evaluates the similarity between the fragment pattern for the size standard dye specified in the size standard definition and the actual distribution of size standard peaks in the sample.</td>
</tr>
<tr>
<td>SSKP</td>
<td>Spike</td>
<td>Indicates if spikes are detected within or between two defined marker size ranges.</td>
</tr>
<tr>
<td>MIX</td>
<td>Possible Mixed Source</td>
<td>Indicates a potential mixed-source sample.</td>
</tr>
<tr>
<td>OMR</td>
<td>Outside Marker Range</td>
<td>Indicates if labeled peaks are detected between two marker size ranges defined in the panel.</td>
</tr>
<tr>
<td>CGQ</td>
<td>Composite Genotyping Quality</td>
<td>Indicates overall sample/allelic ladder quality. Considers the individual marker GQ values.</td>
</tr>
</tbody>
</table>

7. Select a sample from the filtered samples table, then click (Display Plots). The plot for the selected sample will open in a Samples Plot window.

8. Select Data Interpretation 5Dye from the Plot Settings drop-down list.

9. Click (No Table) in the Samples plot toolbar only view the electropherograms.

10. Click to display the electropherogram, marker-level PQV flags and the Quality Value Details (QVD) pane.
E. 1. Each marker header will be either green, yellow or red. A yellow or red marker header indicates that the marker has a **marker-level Process Quality Value (PQV)** flag. At the bottom left of the sample plot is a table of the marker-level Process Quality Value flags, as shown below. The details of the specific marker-level PQV flags will be displayed to the bottom right of the sample plot for the specific marker selected.

![Marker-Level Quality Assessments Table](image)

F. **Examining the Sizing Quality (SQ) Results**

1. A yellow or red flag under SQ indicates that the sizing quality is below the passing range specified in the analysis method. To view the size standard for the sample, select the sample in the Samples table and click **I**.

2. In the Size Match Editor check that all the size standard peaks are present and labeled correctly. They should be called above the analytical threshold and have good morphology. The following are the sizes of the internal lane standard fragments: 60, 65, 80, 100, 120, 140, 160, 180, 200, 225, 250, 275, 300, 325, 350, 375, 400, 425, 450, 475 and 500 bases. The fragments should be assigned as shown below.
H. Reviewing Allelic Ladders

1. GeneMapper ID-X has a built in allelic ladder quality assessment, which:
   a. Evaluates allelic ladders before proceeding to sample analysis.
   b. Flags run folders without at least one passing allelic ladder.
   c. Automatically excludes low-quality ladders from analysis and continues analysis with passing ladders.

2. To check the allelic ladders, select the Analysis Summary tab in the Project window. Check any low-quality ladders by clicking the link under the column for the flagged allelic ladder samples.

3. Select the ladder sample in the filtered samples table and click (Display Plots). The plot for the selected allelic ladder sample will open in a Samples plot.

4. Select Data Interpretation_5Dye from the Plot Settings drop-down list.

5. To investigate why a particular marker failed the allelic ladder quality assessment, click the red or yellow marker header on the plot to display the quality assessment data in the Quality Value Details (QVD) section at the bottom right of the screen.

6. Assess passing allelic ladders and select at least one to use to analyze the samples within the project.

7. After selecting the ladder to use for the project, the other ladders may be deleted from the project, or the Sample Type may be re-assigned as a "Sample". Deleting the ladders cannot be undone.

8. The samples will need to be re-analyzed. Click the green arrow in the toolbar to re-analyze the samples using the selected ladder.

9. NOTE: Sample migration differences over the course of an entire run may result in differences between a particular sample relative to the allelic ladder selected for data analysis in GeneMapper ID-X. Such differences can result in off-ladder allele (OL) designations during GeneMapper ID-X analysis. This situation can be alleviated by averaging allelic ladder sizes for the analysis of the sample(s). This is automatically done in GeneMapper ID-X if the sample type "allelic ladder" is chosen for more than one allelic ladder. This situation may also be alleviated by choosing an allelic ladder for the analysis of the sample(s) that ran closer in time to the sample(s) in question and analyzed as a separate project.

I. Reviewing Control Samples

1. Select the Analysis Summary tab in the Project window.

2. Manually review the control data by clicking the blue hyperlinks within each column. If a control has met all thresholds and the resulting profile was obtained with no anomalies detected, it will be under the "All thresholds met" column.

3. If any samples are flagged under the "One or more thresholds not met" column, investigate the quality of that sample by clicking the hyperlink within that column.

4. Positive Amplification Control
   a. Positive Amplification Control: The positive amplification control (2800M for the PowerPlex Y23 kit) monitors the success of the amplification process. One positive amplification control is required with each amplification assay.
   b. Evaluation of the positive amplification control requires that all expected alleles be adequately amplified (alleles at DYS385 greater than the stochastic threshold of 1100 RFU) and correctly typed at all loci.
   c. If the positive amplification control does not exhibit expected results, the analyst should first assess whether a procedural problem exists. If an error is found, the analyst must take the necessary steps to correct the procedural error and re-evaluate the sample set.
   d. If no procedural error is found, or if the analyst's corrective measures do not produce expected results in the positive controls, the DNA Technical Leader will be notified of the quality issue, and the DNA Technical Lead will have the discretion to decide if the results will be reported. The Unit Supervisor and DNA Technical Lead will review the corrective action and have the discretion to determine the appropriate course of action. Refer to the Corrective Action Policy BIO.5.QAQC.14.
   e. The analyst will document the issue in the case notes. A Level II Quality Incident Report (QIR) form or Corrective Action may be used to document the issue. When the results cannot be reported, it will also be conveyed in the lab report with a brief description of the reason.

5. Negative Controls:
   a. Two negative controls are required with the amplification of each sample set: a reagent blank and a negative amplification control. Negative controls are designed to test for the unintentional introduction of DNA during the DNA process.
   b. Reagent Blank: A reagent blank is a sample containing all the reagents used in the extraction and amplification process, but contains no DNA. The purpose of the reagent blank is to monitor for any possible reagent contamination that might occur at any point in the process, between samples being processed, or from previously amplified product.
   c. Negative Amplification Control: The purpose of the negative amplification control is to monitor the success of the amplification by amplifying a sample with no added DNA. This negative control monitors for DNA contamination in the amplification reagents and PCR set-up environment.
d. The laboratory's tolerance level for contamination is one allele above the analytical threshold. If the reagent blank and negative control should yield a single peak above the analytic threshold, the associated sample data is considered acceptable for reporting purposes. If either of the negative controls exhibit more than one DNA peak above the analytical threshold, the analyst must attempt to identify the cause and document this in the case file. The analyst should evaluate and document whether the contamination is due to a sample switch, sample-to-sample carry-over, from the analyst's own DNA, or due to factors beyond the analyst's control, such as contaminated manufacturer consumables and/or reagents. Note that if there was actual contamination present in the negative amplification control, one would also expect contamination to be detected in the reagent blank. If the amplification kit reagents are found to be contaminated, the samples should be amplified with a new lot, if possible.

e. Identifying the cause of the contamination may require DNA processes to be repeated in order to pin-point where the contamination occurred and to correct the issue, if possible. The analyst may analyze below the standard analytical threshold or enhance the detection of the DNA in the control (increased injection time, more PCR cycles) to aid in troubleshooting the source of the contamination, but this data will not be reported.

f. If a DNA process cannot be repeated because one or more of the associated samples have been consumed, the DNA Technical Leader may permit the reporting of results provided that:
   i. The second reagent blank in the sample set (if relevant) demonstrates that the laboratory’s reagents are not contaminated, and
   ii. The DNA types detected in the negative control are not observed in the sample or
   iii. The typing results in the negative control are significantly lower RFU (at trace levels) than the sample.

g. All instances of failed negative controls will be documented in the case notes. When the failed negative control results in the results not being able to be reported, it must also documented in the lab report with a brief description of the reason.

J. Examining and Evaluating Sample Files
1. Select the Analysis Summary tab in the Project window.
2. Manually review the samples by clicking the blue hyperlinks under each column. If a sample has met all thresholds, it will appear under the "All thresholds met" column.
3. If any samples are flagged under the "One or more thresholds not met" column, investigate the quality of that sample by clicking the hyperlink within that column.
4. The filtered samples table displays the selected samples. Note the and sample-level PQVs for these samples.

K. Designation of Alleles and Artifacts
1. After data has been processed, an analyst examines the peaks that have been called, and based on experience they may or may not edit the calls made by the GeneMapper ID-X software. Decisions to edit a software-designated peak come from an understanding of biological and instrumental artifacts. Any edits will be documented in an analyst's case notes.
2. Locus Designation
   a. Each Y-STR locus has a set of alleles that span a range of base pair sizes, each with a minimum and maximum base pair size.
   b. Alleles are assigned to a locus by virtue of their size and the locus-specific primer attached to the amplicon.
   c. Occasionally an allele may be detected outside of the designated range of expected alleles for a given marker. The allele may fall within a bin or be called "OL" and may be detected in the upper or lower range of an adjacent locus.
   d. A yellow or red PQV flag will be present in the marker-specific PQV box for OVL (overlapping alleles). This indicates that a labeled peak falls within the size ranges of two neighboring markers. An attempt should be made to determine which marker the allele should fall into, but sometimes this is not possible. If the proper locus assignment of the allele cannot be determined, the locus or loci may be designated as inconclusive. Alternatively, the sample may be amplified with a different STR kit to help resolve the true locus of the allele. Any yellow or red marker-level flag in the OVL box will automatically trigger a flag in the sample-level OMR (out of marker range) box.
   e. If an allele falls above the largest allele or below the smallest allele of an allelic ladder or virtual bin of a locus, the allele will be designated as either greater than (>) or less than (<) the respective ladder allele (e.g., 8,>15). When this designation is used, the relative size of the allele should be estimated in order to compare among samples. However, extrapolating an allele designation beyond one repeat unit from the ladder should be avoided.
   f. Occasionally, deletion of a portion of the Y-chromosome or a primer-binding site mutation can result in the failure to detect one or more Y-STR loci.
3. Allele Designation
   a. Allele designations are assigned to sample peaks by comparison of their base pair size to those obtained from the known alleles in the allelic ladder. Numerical allele designations have been assigned in accordance to the recommendations of the International Society of Forensic Genetics (formerly the DNA Commission of the International Society of Forensic Haemogenetics). The GeneMapper-IDX software uses bins, which are specific regions in the electrophoretic space that define the expected sizes for each known allele from a Y-STR locus.
   b. Typically single source Y-STR profiles have one allele at each locus, with the exception of multi-copy loci (in the Y23 kit DYS385 a/b is multi-copy). However, it is possible to have more than one allele at any Y-STR locus. For multi-copy loci, both alleles are reported in order of smallest to largest.
   c. The majority of duplications (~83%) result in alleles that differ in size by 1 repeat unit, while ~17% of duplications involve 2, 3, 4 and partial repeat unit differences. The proximity of certain loci on the Y-chromosome allows for the simultaneous duplication of alleles at multiple loci. Tri-alleles have also been reported at DYS385 a/b and DYS635.
   d. Rare alleles may be encountered in casework that are not represented in the allelic ladder. The GeneMapper-IDX software can accurately label alleles including those not present in the allelic ladder, such as microvariant alleles containing incomplete repeats
that fall within a virtual bin. Other alleles not present in the ladder or that fall outside of a bin may be designated "OL" (off-ladder) by the Genemapper software. When this occurs, the allele designation must be manually calculated. See "f" below.

e. Alleles containing an incomplete repeat motif and also falling within the span of the ladder alleles, are represented by the following convention: the number of complete repeats, followed by a period, and then the number of base pairs between those ladder alleles. Each increment approximately represents the base pair size for each increment. Add the number of increments to the smaller ladder allele to establish a size range that includes the size of the unknown microvariant. Estimate the base pair size range for the increment(s) by calculating the +/- 0.5 base pair range for the increment(s) and compare the values to the microvariant. Alternatively, the Butler method may be used.

f. To designate an off-ladder allele such as a microvariant that falls outside an allelic ladder bin or virtual bin, calculate the size difference between two allelic ladder alleles that bracket the OL allele. Divide the difference by the number of basepairs between those ladder alleles. Each increment approximately represents the base pair size for each increment. Add the number of increments to the smaller ladder allele to establish a size range that includes the size of the unknown microvariant. Estimate the base pair size range for the increment(s) by calculating the +/- 0.5 base pair range for the increment(s) and compare the values to the microvariant. Alternatively, the Butler method may be used.

g. Allelic ladders and virtual bins contain many incomplete repeats for each marker, but some of the more uncommon micro-variants are not and will be labeled OL by the Genemapper ID-X software. A yellow or red PQV flag will be present in the marker-specific PQV box for BIN if labeled peaks do not fall inside a virtual bin for a given marker. Inject these microvariants at least twice to demonstrate reproducibility of sizing for the variant.

4. Labeling an OL as an Allele
   a. To label an OL as an allele, click on the peak label, then right click, and select Rename Allele Label followed by Custom Allele Label.
   b. In the resulting dialog box, enter the allele call and click OK.
   c. In the Reason(s) For Change dialog box, enter the reason for the change (e.g., microvariant), and then click OK.
   d. Select the marker row with the edit and right click on the box for its GQ PQV.

5. Allele designations for samples intended for CODIS entry must conform to the Combined DNA Index System (CODIS) recommendations.

L. Evaluation of Artifacts and Non-allelic Peaks:

1. Artifacts can rise above the analytical threshold in any locus, so it is necessary to identify any potential non-allelic peaks prior to interpretation and comparison of the DNA data. Non-allelic peaks may be the result of the PCR process (amplification driven) or a result of the electrophoresis process (electrophoretic). Non-allelic peaks detected above the analytical threshold will be evaluated and every attempt will be made to identify the type of artifact. The verification of the artifact will be noted in the case file.

2. Stutter: A normal amplification artifact seen as a small peak at a number of repeat units more (e.g., N+4, N+2) or less (e.g., N-2, N-4, N-8) than the primary peak, and is generally a reproducible artifact.

   a. Stutter tends to follow several trends. Alleles with long stretches of the same repeat generally increase the amount of stutter, therefore larger alleles within a locus tend to show greater stutter. Interruptions in the homologous sequence tend to decrease the amount of stutter, hence microvariants with partial repeat structures tend to show less stutter.

   b. Peaks in a stutter position exceeding these values may indicate the presence of a low level contributor, such as in a mixture. However, a true allele may co-locate in a stutter position and may not be detected as a true allele unless it exceeds the stutter threshold value for that locus. These peaks should be considered as possible true allelic peaks if the potential stutter peak height is consistent with or greater than the peak heights observed for the minor contributor (after stutter contribution in the peak has been taken into consideration).

c. A stutter threshold of 15.8% will be applied for forward stutter - two repeats (n+8) at DYS385.

3. Off-scale data: Analyzed peak heights above the optimal range (>30,000 RFU) may be "off-scale" in the raw data, meaning that the CCD camera may be saturated. As a result, the analyzed peak may be assigned a lower value due to smoothing and baselining functions. This can
allow the relative percent stutter for an off-scale peak to appear inordinately high and cause baseline noise to be called above the analytical threshold. If the stutter peak is greater than the established cut-off and the analyzed primary peak is nearing saturation and/or has been labeled with an off-scale flag, the analyst should interpret the results with caution. Mixture samples with off-scale data should not be used when determining minor contributors to a mixture. The amplified product may be diluted and re-injected to help resolve this issue.

4. **Shoulder:** Shoulder peaks are peaks approximately 1-4 base pair (bp) smaller or larger than main alleles. Shoulder peaks can be recognized by their shape; they do not have the shape of an actual peak, rather they are continuous with the primary peak. As a result of poor resolution, a stutter peak may be elevated if it falls within the raised shoulder of a tailing peak. This can lead to an accentuated stutter peak height with ratios above the established cut-off. A loss in resolution defined by broad peaks could also suggest the capillary needs to be replaced.

5. **Pull-up:** The forming of a false peak in a certain dye caused by over-saturation of a true peak in another dye when its fluorescence nears CCD camera saturation. As a result, this phenomenon termed "pull-up" results in small artifact peaks that appear in other colors under the true peak. Pull-up follows a regular order among the dye colors and is detected as a small peak with the same sizing as the over saturated peak.

   a. Spectral overlap between dyes is normally corrected by the spectral calibration. Pull-up results when the spectral calibration cannot correct this spectral overlap due to oversaturation of the CCD camera by greater-than-optimal amounts of fluorescence. To distinguish pull-up peaks: the base pair size should be the same or very close in size to the true peak and the pull-up peak. If a pull-up peak is above the minimum peak height detection threshold, it will be sized at the same size (or close to the same size) as the true peak. Pull-up can occur as a result of the following:

   i. Application of a sub-optimal spectral calibration can cause pull-up. If necessary, a new spectral calibration may need to be run.

   ii. Amplification using excessive input DNA can lead to off-scale peaks (see above). The spectral calibration may not perform properly with off-scale data. The amplified product can be diluted and re-injected to help resolve this issue.

6. **Artifacts Arising from Room Temperature Fluctuations:** Significant room temperature changes during the course of an entire run may cause sample migration differences that result in significant sizing variations between the peaks of the allelic ladder and the samples. Sample peaks differing by more than 0.5 bp from bins may result in off-ladder allele designations during GeneMapper ID-X analysis. This may be alleviated by analyzing a different injection of the allelic ladder that more closely represents the migration of the sample(s). Multiple allelic ladders are typically injected throughout the course of a run in order to compensate for the difference in sample migration. If necessary, the sample(s) and the allelic ladder may be re-injected until a match in migration is found.

7. **Dye Blobs or Dye Artifacts:** Dye blobs are non-allelic peaks thought to be caused by fluorescent dye molecules that have detached from the primer. Dye blobs can exist in all of the fluorescent dye colors. They are typically distinguishable from allelic peaks in an electropherogram by their broad irregular shaped morphology. Dye blobs are typically reproducible between injections, but may be resolved with different reagents/chemistry. Once determined to be an artifact, edit it as such, or apply a higher analysis threshold to remove the artifact.

8. **Spikes:** Spikes can be the result of electrical fluctuations during the electrophoresis process, due to the presence of crystal formations in the polymer (POP-4), or due to air bubbles traveling past the laser detector window. Spikes are generally narrow peaks that occur at various heights and are typically represented in multiple dye channels. If the peak has been determined to be an artifact, it can be edited as such, or a higher analysis parameter can be applied to the data to remove the artifact. Spikes are typically not reproducible and re-injecting the sample should resolve the suspected spike artifact.

   a. GeneMapper ID-X may automatically label a spike artifact as **“spike”** with a pink border on the electropherogram. To confirm the spike:

   i. **Select Peak Raw Data** from the drop-down menu.

   ii. Review the raw data and peak morphology to confirm that the selected peak is a spike.

9. **Elevated Baseline fluctuation:** Fluorescent background noise is an artifact of the electrophoresis process. Normal variation in the baseline can be seen at very low relative fluorescent levels. Background fluorescence is generally below the analytical threshold, however, occasional raised baselines or baseline noise labeled above the analytical threshold can be observed. If the peak has been determined to be an artifact, edit it as such, or apply a higher analysis parameter to correct for the elevated background noise. Raised baselines are typically not reproducible between injections, thus the sample should be re-injected to assist in interpreting the data. Elevated baselines may be indicative of an improperly functioning spectral. The analyst may choose to run a new spectral calibration or dilute and re-inject the sample to help resolve this issue.

10. **Poor Injections:** The genetic analyzer applies a voltage to the DNA sample to draw it into the capillary. The efficacy of the injection can be affected by the levels of salt in a sample. Salt ions compete with DNA molecules, causing less DNA from a sample to be preferentially injected into the capillary. As a result, different injections of the same sample can vary in signal intensities. Poor capillary and electrode alignment as well as bubbles in the sample tube or pump block can also cause poor injections. Capillaries must not be allowed to dry out. Polymer crystals forming around the capillary opening can form a physical obstruction resulting in poor or no current. A failing capillary may also display symptoms of a poor injection, such as broad peaks.

11. Several DNA-Dependent artifacts and DNA-Independent artifact peaks may be observed with the PowerPlex Y23 System. They are listed in the table below.
13. Editing Artifacts

a. To label a peak as an artifact, click on the peak label, then right click and select **Rename Allele Label** and the **Custom Artifact Label**. Complete the custom artifact label dialog box using the appropriate abbreviation from the table below, click **OK**.

i. In the Reason(s) For Change dialog box, enter a reason for the edit, using the abbreviations below then click **OK**. The reason typed into this box will appear on the electrophrogram. The marker header will turn grey.

M. Data for Notes

1. Duplicate sample files can be deleted from the GeneMapper ID-X project but all collection files are maintained electronically in the run folder. Printouts of the GeneMapper ID-X electropherograms for all samples being reported as well as corresponding substrate controls (if applicable) are to be included in the case packet. Printouts of the amplification positive and negative controls, QC sample, reagent blanks, allelic ladders and WEN ILS standards are not necessary for the case packet. These will be reviewed electronically during technical review.

2. Multiple amplification and/or injections: All raw data files are kept in the run folder including data not used for analysis or interpretation. In the event that a sample has undergone multiple amplifications or injections, the analyst will use the result with the most genetic information for comparison and statistical calculations. The sample used for interpretation must be printed out for the case file. Creation of a composite profile will not be done.

N. Saving the Project

1. The GeneMapper ID-X project must be saved prior to exporting. To save the project, select **File>Save Project As** and use the naming convention mentioned previously. If the project is closed prior to saving, GeneMapper ID-X will automatically prompt with, “Do you want to save changes?” Click “Yes.”

O. Exporting the Project

1. After analysis is complete, export the project by opening **Tools>GeneMapper Manager**, select the project to export and click the Export button. Export the project to its corresponding case folder within the appropriate Run Folder on the laboratory's internal network drive. This is typically done after technical review.

P. Creating the Data Summary Table

1. Refer to the instructions contained in the Excel workbook, "Y23 Summary."

Q. Documenting Results on the Summary Data Sheet

1. The Summary Data Sheet will contain, at a minimum, the analyzed DNA results from all references and evidence samples. These results will be interpreted, and from the interpretation, a conclusion will be drawn, when applicable.

2. One sample row will contain the raw data. Another sample row should be created when the analyst is able to interpret a major or minor contributor's profile.
II. Interpretation of Y-STR Data

A. Introduction

1. The interpretation of results is a matter of professional judgment and expertise. Not every situation can be covered by a pre-set rule nor is it reasonable to expect competent analysts to always be in full agreement with the interpretation of every case. However, it is the goal of the laboratory to develop criteria, based on validation studies, users' manuals, literature references, and casework experience to provide a framework for objective interpretation of results that all analysts can follow. As technology progresses and the laboratory’s experience evolves with it, these interpretation guidelines will continue to evolve.

2. The purpose of these guidelines is to establish an outline to ensure interpretations are made as objectively and consistently as possible from analyst to analyst and to ensure reported conclusions are scientifically supported by the analytical data.

3. The Biology Unit’s Interpretation Guidelines are patterned after the SWGDAM Interpretation Guidelines for Y-Chromosome STR Testing (2014).

B. Thresholds used for Data Analysis and Interpretation

1. Analytical Threshold (AT): The minimum height requirement at and above which peaks can be reliably distinguished from background noise. Based on validation data, the minimum peak height threshold is 140 RFU for the blue, green, orange, and red dyes and 210 for the yellow dye. While peaks can be observed below the analytical threshold and may indicate the presence of a true allele, peaks below these levels will not be registered as alleles for reporting purposes.

2. Stochastic Threshold: The stochastic threshold (ST) is the peak height above which it is reasonable to assume that dropout of a sister allele of a heterozygote pair has not occurred.
   a. The stochastic threshold is not applicable to single copy Y-STR loci and therefore will only be used in the interpretation of alleles detected at DYS385. Based on validation data, the stochastic threshold is 1100 RFU.
   b. Low template amplifications may result in drop-out of a duplicated allele at a Y-STR locus that is typically single-copy. While duplications have been observed in single-copy Y-STR loci, they are rare. In view of this, a reasonable profile frequency estimate will generally be obtained by searching the database using the observed allele. Accounting for an undetected second allele would not result in a practical difference in probability.

3. Peak Height Ratios
   a. Peak height ratios (PHR) are calculated by dividing the peak height (in RFUs) of the lower RFU allele by the peak height of the higher RFU allele, and then multiplying by 100 to express the PHR as a percentage.
   b. If two alleles are detected at locus DYS385, the peak height ratio between the two alleles should be ≥60% for samples 4000 RFU and higher and ≥30% for peaks between 1100 RFU and 3999 RFU. However, lower peak height ratio imbalance may be observed in samples with low template amount, degraded DNA or in the presence of PCR inhibitors.
   c. Peak height ratio's will also be used to determine major versus minor alleles in a Y-STR mixture. See mixture interpretation section below.

4. Steps of Y-STR Data Interpretation
   a. The interpretation of DNA data is considered a combination of qualitative and quantitative assessment. An analyst should note all analysis and interpretation observations within the case notes. This can be done on the electropherogram, a mixture worksheet, or a separate note page. Mixture deconvolutions require documentation of all assumptions used, including but not limited to the assumed number of contributors, any known contributors, and assumptions regarding those contributors, where applicable. This documentation must be included in the report.
   b. Interpretation of the evidence samples must be performed prior to any comparison to known haplotypes.
   c. Step 1: Characterize the quality of the amplification
      i. Inhibition is when a substance is present in the DNA sample that affects the amplification reaction. An excessive amount of female DNA (Female to Male ratio >2000:1) in a sample may inhibit Y-STR amplification. An increased amount of male DNA template may result in successful amplification.
      ii. Degradation is when the DNA molecule has been broken into small pieces due to environmental insult or other factors. This results in a gradual loss of signal affecting the high molecular weight loci first and is often observed as a downward ski slope pattern. Degraded DNA can result in partial DNA profiles or no DNA results because the DNA fragments could not be amplified.
      iii. Differential Degradation is where contributors to a DNA mixture possess different degrees of degradation. This is of particular importance with mixture interpretation where different contributions to a DNA mixture may have different levels of degradation; this could have a significant impact on interpreting mixture ratios across the profile depending on the severity of the disproportionate degradation.
      iv. When evaluating any DNA data, it is dependent on the observations of the quality and quantity of the data.
   1. Quantity: Evaluate whether the data in the sample is detected at low or at optimal RFU levels. The overall quantity of DNA in the sample will have an effect on the overall allele height intensities.
2. \textbf{Quality:} Evaluate those loci for which quality issues are suspected and where drop out of alleles due to degradation, inhibition, or stochastic affects is possible.

\begin{itemize}
  \item[v.] When evaluating the overall quality and quantity of the sample, the analyst should consider whether the DNA data across all typeable loci is detected at a level where the number of contributors can be confidently assumed and whether there is data at a sufficient number of loci to clearly assess the number of contributors.

  \item[vi.] Should the DNA quality/quantity objectively limit determining or assuming the number of contributors in the sample, the DNA results will be deemed insufficient for further interpretation and no conclusions will be offered.

  \item[vii.] If the quality of the data allows the number of contributors to be determined or assumed, proceed to step 2. In some instances when the number of contributors can be assumed, but the sample contains loci affected by unresolved quality issues, those loci may not be considered for interpretation and comparison.
\end{itemize}

\textbf{d. Step 2: Determining whether the sample is single source or a mixture}

\begin{itemize}
  \item[i.] All DNA data falls into two categories: single source or mixture. To assess the number of contributors, all alleles above the analytical threshold will be used. Peaks below the analytical threshold may be observed and may aid in determining if a sample is single source or a mixture.

  \item[ii.] \textbf{Single Source Profiles}

    \begin{itemize}
      \item[1.] When DNA data represented in a full profile contains no more than one allele at the single copy loci and no more than two alleles at the multi-copy locus, it is highly probable the DNA results are attributable to a single contributor. Exceptions to the one (or two) allele maximum per locus rule have been documented, as persons with duplications, or primer binding site variations.

      \item[2.] Any sample that exhibits less than a complete profile is considered a partial profile. Partial profiles can result from degraded or inhibited samples or samples originating from low quantity. A partial profile contains less genetic information for assessing the potential number of contributors in the sample; therefore, caution is needed when determining whether the observed DNA originated from a single contributor. Partial profiles, while expressing less genetic information than a full profile, may still provide useful information for purposes of inclusion and exclusion.

      \item[3.] The minimum number of loci for inclusion/exclusions is 15 loci.

      \item[4.] In single source profiles with an allele below the stochastic threshold (1100 RFU) at DYS385 the possibility of allelic dropout must be considered and this locus considered partial.
\end{itemize}

  \item[iii.] \textbf{Mixture Profiles}

    \begin{itemize}
      \item[1.] Evaluating the number of contributors in a mixture entails considering the number of alleles at all loci, the peak height ratio of alleles at DYS385, and the presence of peaks in stutter positions that are significantly higher than the stutter threshold. Generally a sample is considered to be a mixture of more than one individual if two or more alleles are present at two or more single-copy loci, and/or peak height ratios fall outside of the expected ranges at the multi-copy locus.
\end{itemize}

\end{itemize}

\textbf{e. Step 3: Determine the minimum number of contributors in a mixture}

\begin{itemize}
  \item[i.] The minimum number of contributors can typically be estimated based on the single-copy locus with the greatest number of alleles. A mixture of two males is expected to contain no more than two alleles per locus (up to four alleles at DYS385). A mixture of three males is expected to contain no more than three alleles per locus (up to six alleles at DYS385).

  \item[ii.] Barring mutation, all males within a maternal bloodline will have the same Y-STR profile and therefore the actual number of males in a mixture will not be able to be determined when relatives may be contained within a mixture.
\end{itemize}

\textbf{f. Step 4: Consider and factually describe known information from which reasonable inferences can be assumed about the sample.}

\begin{itemize}
  \item[i.] \textbf{Intimate Samples:} An intimate sample is any sample where there is a reasonable expectation that an individual's DNA would be present. These include samples that originate directly from an individual's body (such as fingernails, hair, body orifice or body swabs), as well as clothing belonging to/removed from an individual. An analyst can make the assumption that an individual's DNA may be present on their intimate sample. This assumption must be stated in the case notes.

  \item[ii.] Once the assumed person is determined to be present in the mixture, the individual’s contribution to the mixture can be accounted for and used to deduce the profile of the remaining contributor in the mixture.
\end{itemize}

\textbf{g. Step 5: Characterize the DNA contribution ratio of each contributor in the mixture, if possible.}

\begin{itemize}
  \item[i.] \textbf{Mixtures of Two Contributors}

    \begin{itemize}
      \item[1.] A ratio of the major contributor to the minor contributor should be calculated for the loci where allele sharing between contributors is not occurring. A minimum mixture ratio of 3:1 should be seen between contributors to determine if the profile contains a single major contributor (distinguishable mixture).

      \item[2.] Major peaks should be at a minimum of 1100 RFUs to be considered for the interpretation of a major contributor.

      \item[3.] When stutter may be significantly contributing to the height of a potential minor allele, the maximum expected stutter percentage can be subtracted out of the height of the peak before calculating the mixture ratio.

      \item[4.] Application of Peak Height Ratios to determine major contributor:

        \begin{itemize}
          \item[1.] \textit{Single-copy loci:}

            \begin{itemize}
              \item[1.] The peak height ratio must be \textless{}45\% between the major and minor allele, when two alleles are present and the major contributor is greater than 4000 RFU, and \textless{}30\% between the major and minor allele when the major allele is less than 4000 RFU.
            \end{itemize}

          \item[2.] \textit{Multi-copy loci}
        \end{itemize}
    \end{itemize}
\end{itemize}
Step 7: Comparison with Known Samples and Conclusions:

i. Exclusion (elimination): A known reference sample will be reported as "excluded" when a sample has no contributors to an individual. Statistical calculations will be performed to state an exclusion.

ii. Inclusion (match): A known reference sample will be reported as "included" when a sample matches the reference haplotype. Statistical calculations will be performed to state an inclusion.

iii. Inconclusive: A conclusion of "inconclusive" is reported when a sample may contain a partial haplotype (less than 15 interpretable loci), for example, as a result of allelic dropout, stochastic effects, degradation, or a low amount of template DNA. These Y-STR mixtures may be used for exclusionary purposes but are not required to support the inclusion of an individual on his or her own intimate sample.

iv. No results: A conclusion of "no result" is reported when no amplified DNA has been detected above the analytical threshold at any locus.

Step 8: Statistical Analysis

i. Once a questioned sample is compared to a known reference and an inclusion is made, a frequency estimation of the haplotype must be determined. All inclusions of a probative nature will have a statistical interpretation provided. Statistical calculations are not required to support the inclusion of an individual on his or her own intimate sample.

ii. Statistical calculations shall be performed on single source profiles and deduced major/minor contributors with a minimum of 15 loci.

iii. All Y-STR loci analyzed in the Y23 kit are physically linked on the Y-chromosome, therefore the entire Y-chromosome haplotype must be treated as a single locus. Haplotype frequencies are estimated using the counting method.

iv. The counting method involves searching a given haplotype against a population database to determine the number of times the haplotype is observed in that database. The frequency of the haplotype in the database is then estimated by dividing the count by the number of haplotypes searched.

v. A Y-STR haplotype frequency estimation is calculated from the observed haplotype frequency estimate by attaching a 95% confidence interval to capture the effect of database size.

vi. Haplotype Frequency (p) = x/N where x is the number of times the haplotype is observed in a database containing N number of haplotypes.

1. If the haplotype has not been previously observed in the database, the formula for calculating the upper 95% confidence limit is: 1-(0.05)1/n where n is the database size.
2. If the haplotype is observed in the database, the formula used for calculating the 95% confidence limit is that of an exact confidence interval, using the formula as described by Clopper and Pearson.
vii. The laboratory will use the YHRD database (http://YHRD.org) or DOJ's Y-Mix Filter 4.2 to determine haplotype frequencies.

viii. Entry of the haplotype profile into the database must be performed per the user directions provided on the YHRD Database website or in the Y-Mix Filter workbook, whichever is used. Both statistical tools calculate the haplotype frequency and profile probability estimates using the 95% confidence interval.

ix. The search must include all populations and results will be reported for Caucasians, African Americans, Hispanics, and Asians.

x. The result for the search will be printed out for the case file and saved on the laboratory's internal network drive in the case folder contained within the 3500 run folder.

xi. The statistical calculations must be reported to the same number of significant figures as displayed on the results sheet.

xii. Reduced Locus Searches

1. Because there are more Y-STR haplotypes from Yfiler in the databases, haplotype searches should be conducted using the Y23 loci and the Yfiler loci. This typically avoids the situation where more loci yield a less discriminating frequency estimate because there are fewer database entries with the more discriminating set.

2. Regardless of the number or selection of loci searched, the most discriminating search is generally the one which gave the lowest proportion of matching haplotypes per number of profiles compared.

3. When performing reduced locus searches, any “matches” that would have been non-matches had more of the evidence profile been searched should be excluded. The comparisons should be included in the case file and the number of matching haplotypes should be adjusted accordingly. The Y-Mix Filter, which contains the US haplotypes from the YHRD database R60, is typically used to perform reduced locus searches because the database profiles can be viewed and easily reduced manually.

4. The upper 95% confidence interval must be manually calculated when a search is performed at a reduced number of loci and the number of matching haplotypes has been reduced due to non-matching alleles at the additional (non-searched) loci. The adjusted confidence interval should be calculated using the Excel formula =BETAINV(0.95,x+1,N-x); where 0.95 is the confidence interval upper bound, x is the number of matching haplotypes, and N is the total number of haplotypes compared.

C. Reporting

1. Single Source Profiles

   a. Match: The result should be reported as: "The single source Y-STR/partial Y-STR profile obtained from (the evidence item description and #) matches/is consistent with the Y-STR profile from (known sample and item #)" or similar.

   b. Exclusion: The result should be reported as: "The Y-STR profile obtained from (Name) is excluded as the source of the Y-STR profile obtained from (the evidence item description and #)" or similar.

2. Mixtures

   a. The result should be reported as: "A Y-STR mixture of (# of contributors) males was obtained from (the evidence item description and #). The Y-STR profile for the major/minor contributor obtained from the mixture matches the profile of (Name) or The Y-STR profile obtained from (Name) is excluded as the source of the major/minor Y-STR profile obtained from the mixture" or similar.

3. Mixture with intimate contributor

   a. The result should be reported as: "A Y-STR mixture of (# of contributors) males was obtained from (the evidence item description and #). (Name) is an assumed contributor due to the intimate nature of the sample. The Y-STR profile obtained for the major/minor contributor obtained from the mixture matches the profile of (Name) or The Y-STR profile obtained from (Name) is excluded as the source of the major/minor Y-STR profile obtained from the mixture" or similar.

4. Indistinguishable mixture for exclusionary purposes only

   a. The result should be reported as: "An indistinguishable mixture of two contributors/at least two contributors was obtained from (the evidence item description and #). (Name) appears to be excluded as a contributor to the mixture. However, due to the nature of the data, the results for this Y-STR mixture are unsuitable for inclusions" or similar.

5. Inconclusive

   a. The result should be reported as: "A Y-STR mixture of at least (# of contributors) males was obtained from (the evidence item description and #). The Y-STR profile is inconclusive due to the complexity of the data/low level/number of contributors" or similar.

6. No Result

   a. The result should be reported as "No Y-STR DNA results were obtained" or similar.

7. Statistical Statements

   a. May be reported as: Therefore, (name) and any male paternal relatives are included as potential DNA donors to this sample. Using the YHRD Database, this Y-STR profile has been observed:

      i. X in n African American males
         X in n Caucasian males
         X in n Hispanic males
         X in n Asian males

      ii. Applying the 95% upper confidence interval results in approximately:

         1 in every __ African American males
         1 in every __ Caucasian males
         1 in every __ Hispanic males
         1 in every __ Asian males
iii. Where X is the number of times the profile was seen in the database and n is the number of profiles in the database

I. Procedure for the use of GeneMapper ID-X software to analyze PowerPlex Fusion 6C Data

A. Materials:
   1. GeneMapper ID-X v 1.5 software

B. Analyzing Data Files using GeneMapper ID-X v 1.5 Software
   1. NOTE: A separate GeneMapper ID-X project will be created for samples interpreted using STRmix. See BIO.2.DNA.13 section "Creating Tables in GeneMapper ID-X v1.5 to export into STRmix v2.6" for instructions on creating those projects.
   2. GeneMapper ID-X (GMIDX) software is used to size DNA fragments and assign genotypes using one or more allelic ladder(s) and an internal lane standard.
   3. The data collection files must be retained on the 3500 computer until archived in the following location: C:/AppliedBiosystems/Runs/ {Unique Run Folder}.
   4. Open GeneMapper ID-X and log into the software. The username is gmidx followed by your initials, then enter the password. NOTE: The computer with the Full Installation must be on to access GeneMapper ID-X from a computer with a Client Installation.
   5. Create a new project by selecting Add Samples to Project under the Edit menu, or click .
   6. In the Files tab of the Add Samples to Project window, locate the correct sample files and click Add to List. The run folder(s) should appear in the column on the right under Samples to Add. When done adding samples files, click Add on the bottom right of the window.
   7. View Raw Data and Sample Information: Click on the run folder on the left and expand the file to view the list of sample files within the folder. To view the sample info, click on a sample file. To view the raw data, click on a sample file and then click the Raw Data tab on the right. Check the raw data of each sample file to make sure the samples ran correctly on the genetic analyzer, including resolution, spikes, and baseline. To view the electrophoresis, power, and temperature (EPT) data, click on the EPT Data tab. When finished viewing, return to the main window by clicking on the run folder or the project icon.
   8. Begin the analysis in the Project window using the “CCC Fusion” Table Settings within the Samples tab of GeneMapperID-X. Remove sample files that are not needed by selecting Delete from Project under the Edit menu. Note: this move cannot be undone. Make sure that all "Sample Types" are set correctly. Allelic ladders should be set to Allelic Ladder, 2800M control should be set to Positive Control, and the negative control and reagent blanks should be set to Negative Control. All others should be assigned as a Sample.
   9. In the Project Window, apply analysis settings:
      a. Under the Analysis Method column, select "PowerPlex Fusion 6C" or "FUSION XXXX" based on the analysis start point being used.
      b. Click the Analysis Method column header to select the column. Under the Edit menu, select Fill Down (or use keyboard shortcut "Ctrl+D").
c. Different analysis methods/parameters may be used within a project. Variations can occur within a run that may require the use of different analysis start points. Samples can have varying quality issues, such as low level DNA, off-scale DNA and/or may contain artifacts. The analyst may use an RFU level that is appropriate for analysis of the data. The analysis RFU threshold selected can be any value ranging between the analytical threshold (80/110RFU) and the stochastic threshold (600 RFU), but is typically the analytical threshold.

d. Under the Panel column, select "PowerPlex_Fusion_6C_Panels_IDX_v1.1". Click the Panel column header to select the column. Under the Edit menu, select Fill Down (or use keyboard shortcut "Ctrl+D").

e. Under the Size Standard column, select "WEN_ILS_500_CS". Click the Size Standard column header to select the column. Under the Edit menu, select Fill Down (or use keyboard shortcut "Ctrl+D").

10. Click the Analyze button. When prompted, name and save the project using the convention: GMX XX-XXXXX-X_AAA, where X refers to the Laboratory Case Number and AAA refers to the analyst's initials. Save the GMX project to the Security Group. The software will begin data analysis.

C. Viewing Data

1. When analysis is completed, the software identifies any conditions that may prevent analysis or cause unexpected results. It sets a flag for the Analysis Requirements Not Met (ARNM) Process Quality Value (PQV) and displays the Analysis Requirements Summary (ARS) if a sample in the project does not meet one or more analysis requirement(s).

2. There are three tabs available from the main screen after samples are analyzed. They are as follows: Samples, Analysis Summary and Genotypes.

3. The Analysis Summary tab:

   a. Provides a summary of the analysis status for all or a subset of samples in a project.

   b. Displays an overview of allelic ladder, control, and sample quality.

   c. Visually separates passing samples from samples that do not meet one or more quality thresholds.

   d. Allelic ladders, control samples, and samples where all thresholds are met will be listed in the “All thresholds met” column. Samples that have not met all quality thresholds will be listed in the “One or more thresholds not met” column.
The samples can be displayed in each of these columns by clicking on the blue hyperlinked number within the column.

The hyperlink will open up a filtered samples tab. Each sample in the table will have sample-level Process Quality Value (PQV) flags as shown below:

### Process Quality Value (PQV) Flags

<table>
<thead>
<tr>
<th>Acronym</th>
<th>Full Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SOS</td>
<td>Sample Off-Scale</td>
<td>Indicates if any fluorescence signal within the analysts range exceeds the detection threshold of the instrument</td>
</tr>
<tr>
<td>SQ</td>
<td>Sizing Quality</td>
<td>Evaluates the similarity between the fragment pattern for the size standard dye specified in the size standard definition and the actual distribution of size standard peaks in the sample.</td>
</tr>
<tr>
<td>SSPK</td>
<td>Spike</td>
<td>Indicates if spikes are detected within or between two defined marker size ranges.</td>
</tr>
<tr>
<td>MIX</td>
<td>Possible Mixed Source</td>
<td>Indicates a potential mixed-source sample.</td>
</tr>
<tr>
<td>OMR</td>
<td>Outside Marker Range</td>
<td>Indicates if labeled peaks are detected between two marker size ranges defined in the panel.</td>
</tr>
<tr>
<td>CGQ</td>
<td>Composite Genotyping Quality Values</td>
<td>Indicates overall sample/allelic ladder quality. Considers the individual marker GQ values</td>
</tr>
</tbody>
</table>

4. Select a sample from the filtered samples table, then click (Display Plots). The plot for the selected sample will open in a Samples Plot window.

5. Select Data Interpretation_6Dye from the Plot Settings drop-down list.

6. Click (No Table) in the Samples plot toolbar only view the electropherograms.

7. Click to display the electropherogram, marker-level PQV flags and the Quality Value Details (QVD) pane.
8. Each marker header will be either green, yellow or red. A yellow or red marker header indicates that the marker has a **marker-level Process Quality Value (PQV)** flag. At the bottom left of the sample plot is a table of the marker-level Process Quality Value flags, as shown below. The details of the specific marker-level PQV flags will be displayed to the bottom right of the sample plot for the specific marker selected.

9. D. Examining the Sizing Quality (SQ) Results

1. A yellow or red flag under SQ indicates that the sizing quality is below the passing range specified in the analysis method. To view the size standard for the sample, select the sample in the Samples table and click [ ] .

2. In the Size Match Editor check that all the size standard peaks are present and labeled correctly. They should be called above the analytical threshold and have good morphology. The following are the sizes of the internal lane standard fragments: 60, 65, 80, 100, 120, 140, 160, 180, 200, 225, 250, 275, 300, 325, 350, 375, 400, 425, 450, 475 and 500 bases. The fragments should be assigned as shown below.

   WEN ILS 500 Size Standard
E. Reviewing Allelic Ladders

1. GeneMapper ID-X has a built in allelic ladder quality assessment, which:
   a. Evaluates allelic ladders before proceeding to sample analysis.
   b. Flags run folders without at least one passing allelic ladder.
   c. Automatically excludes low-quality ladders from analysis and continues analysis with passing ladders.

2. To be considered passing, a ladder must:
   a. Have all ladder alleles specified in the panel detected.
   b. Have a peak height ratio of greater than 50% between adjacent peaks. This eliminates allelic ladders where the stutter peak is called as an allele.
   c. Have no spikes detected above 20% of the highest allele peak in the same dye color.
   d. Have a peak height ratio between the lowest and highest peak that is greater than or equal to 15%.

3. To check the allelic ladders, select the Analysis Summary tab in the Project window. Check any low-quality ladders by clicking the link under the column for the flagged allelic ladder samples.

4. Select the ladder sample in the filtered samples table and click (Display Plots). The plot for the selected allelic ladder sample will open in a Samples plot.

5. Select Data Interpretation_6Dye from the Plot Settings drop-down list.

6. To investigate why a particular marker failed the allelic ladder quality assessment, click the red or yellow marker header on the plot to display the quality assessment data in the Quality Value Details (QVD) section at the bottom right of the screen.

7. Assess passing allelic ladders and select at least one to use to analyze the samples within the project.

8. After selecting the ladder to use for the project, the other ladders may be deleted from the project, or the Sample Type may be re-assigned as a "Sample". Deleting the ladders cannot be undone.

9. The samples will need to be re-analyzed. Click the green arrow in the toolbar to re-analyze the samples using the selected ladder.

10. NOTE: Sample migration differences over the course of an entire run may result in differences between a particular sample relative to the allelic ladder selected for data analysis in GeneMapper ID-X. Such differences can result in off-ladder allele (OL) designations during GeneMapper ID-X analysis. This situation can be alleviated by averaging allelic ladder sizes for the analysis of the sample(s). This is automatically done in GeneMapper ID-X if the sample type “allelic ladder” is chosen for more than one allelic ladder. This situation may also be alleviated by choosing an allelic ladder for the analysis of the sample(s) that ran closer in time to the sample(s) in question and analyzed as a separate project.

F. Reviewing Control Samples

1. Select the Analysis Summary tab in the Project window.

2. Manually review the control data by clicking the blue hyperlinks within each column. If a control has met all thresholds and the resulting profile was obtained with no anomalies detected, it will be under the "All thresholds met" column.

3. If any samples are flagged under the "One or more thresholds not met" column, investigate the quality of that sample by clicking the hyperlink within that column.

4. Positive Amplification Control and Quality Control Sample
   a. Positive Amplification Control: The positive amplification control (2800M for the PowerPlex Fusion 6C kit) monitors the success of the amplification process. One positive amplification control is required with each amplification assay.
   b. Quality Control (QC) Sample: A QC sample is a sample, typically blood, that has been previously typed. Although a QC sample is optional, when it is included, it can monitor for each analytical process, specifically verification of the extraction process. A QC sample is typically included when samples are expected to contain low DNA template.
   c. Evaluation of the positive amplification control and QC sample requires that all expected alleles be adequately amplified (homozygous alleles greater than the stochastic threshold of 600 RFU) and correctly typed at all loci.
   d. If either the positive amplification control or QC sample do not exhibit expected results, the analyst should first assess whether a procedural problem exists. If an error is found, the analyst must take the necessary steps to correct the procedural error and re-evaluate the sample set.
e. If no procedural error is found, or if the analyst’s corrective measures do not produce expected results in the positive controls, the DNA Technical Leader will be notified of the quality issue, and the DNA Technical Lead will have the discretion to decide if the results will be reported. The Unit Supervisor and DNA Technical Lead will review the corrective action and have the discretion to determine the appropriate course of action. Refer to the Corrective Action Policy BIO.5.QAQC.14.

f. The analyst will document the issue in the case notes. A Level II Quality Incident Report (QIR) form or Corrective Action may be used to document the issue. When the results cannot be reported, it will also be conveyed in the lab report with a brief description of the reason.

5. Negative Controls:
   a. Two negative controls are required with the amplification of each sample set: a reagent blank and a negative amplification control. Negative controls are designed to test for the unintentional introduction of DNA during the DNA process.
   b. Reagent Blank: A reagent blank is a sample containing all the reagents used in the extraction and amplification process, but contains no DNA. The purpose of the reagent blank is to monitor for any possible reagent contamination that might occur at any point in the process, between samples being processed, or from previously amplified product.
   c. Negative Amplification Control: The purpose of the negative amplification control is to monitor the success of the amplification by amplifying a sample with no added DNA. This negative control monitors for DNA contamination in the amplification reagents and PCR set-up environment.
   d. The laboratory's tolerance level for contamination is one allele above the analytical threshold. If the reagent blank and negative control should yield a single peak above the analytic threshold, the associated sample data is considered acceptable for reporting purposes. If either of the negative controls exhibit more than one DNA peaks above the analytical threshold, the analyst must attempt to identify the cause and document this in the case file. This should be done by including the electropherogram for the negative control.
   e. The analyst should evaluate and document whether the contamination is due to a sample switch, sample-to-sample carry-over, from the analyst's own DNA, or due to factors beyond the analyst's control, such as contaminated manufacturer consumables and/or reagents. Note that if there was actual contamination present in the negative amplification control, one would also expect contamination to be detected in the reagent blank. If the amplification kit reagents are found to be contaminated, the samples should be amplified with a new lot, if possible.
   f. Identifying the cause of the contamination may require DNA processes to be repeated in order to pin-point where the contamination occurred and to correct the issue, if possible. The analyst may analyze below the standard analytical threshold to aid in troubleshooting the source of the contamination, but this data will not be reported.
   g. If a DNA process cannot be repeated because one or more of the associated samples have been consumed, the DNA Technical Leader may permit the reporting of results provided that:
      i. The second reagent blank in the sample set (if relevant) demonstrates that the laboratory’s reagents are not contaminated, and
      ii. The DNA types detected in the negative control are not observed in the sample, or
      iii. The typing results in the negative control are significantly lower RFU (at trace levels) than the sample.
   h. All instances of failed negative controls will be documented in the case notes. When the failed negative control results in the results not being able to be reported, it must also be documented in the lab report with a brief description of the reason.

6. Substrate Controls:
   a. When appropriate, a portion of the substrate adjacent to a questioned stain should be sampled to check for human material in the substrate background. The substrate should duplicate the environment of the stain and be close enough to the stain to pick up endogenous DNA contamination, but far enough to avoid undetected portions of the stain. The substrate control is not expected to be negative and should be treated in the same manner as the stain. If the stain is diluted or concentrated, the same must be done equally to the substrate.
   b. When interpreting the DNA results, there must be a clear difference in the amount of DNA in the evidence sample when compared to the substrate control in order to conclude that the detected fluid or stain is responsible for the DNA results rather than the background. The taking of a substrate control becomes more deliberate and necessary when the stain material in the substrate background. The substrate should duplicate the environment of the stain and be close enough to the stain to pick up endogenous DNA contamination, but far enough to avoid undetected portions of the stain. The substrate control is not expected to be negative and should be treated in the same manner as the stain. If the stain is diluted or concentrated, the same must be done equally to the substrate.
   c. Identifying the cause of the contamination may require DNA processes to be repeated in order to pin-point where the contamination occurred and to correct the issue, if possible. The analyst may analyze below the standard analytical threshold to aid in troubleshooting the source of the contamination, but this data will not be reported.
   d. If a DNA process cannot be repeated because one or more of the associated samples have been consumed, the DNA Technical Leader may permit the reporting of results provided that:
      i. The second reagent blank in the sample set (if relevant) demonstrates that the laboratory’s reagents are not contaminated, and
      ii. The DNA types detected in the negative control are not observed in the sample, or
      iii. The typing results in the negative control are significantly lower RFU (at trace levels) than the sample.
   e. All instances of failed negative controls will be documented in the case notes. When the failed negative control results in the results not being able to be reported, it must also be documented in the lab report with a brief description of the reason.

G. Examining and Evaluating Sample Files
   1. Select the Analysis Summary tab in the Project window.
   2. Manually review the samples by clicking the blue hyperlinks under each column. If a sample has met all thresholds, it will appear under the “All thresholds met” column.
   3. If any samples are flagged under the “One or more thresholds not met” column, investigate the quality of that sample by clicking the hyperlink within that column.
4. The filtered samples table displays the selected samples. Note the ▶ and ◁ sample-level PQVs for these samples.

H. **Designation of Alleles and Artifacts**

1. After data has been processed, an analyst examines the peaks that have been called, and based on experience they may or may not edit the calls made by the GeneMapper ID-X software. Decisions to edit a software-designated peak come from an understanding of biological or instrumental artifacts. Any edits will be documented in an analyst's case notes.

2. **Locus Designation**
   a. Each STR locus has a set of alleles that span a range of base pair sizes, each with a minimum and maximum base pair size range. The span of alleles at each locus is reflective of the span of alleles in the allelic ladder. Bins are provided by the manufacturer that enable electrophoretic peaks to be designated as STR alleles for each tested locus, consisting of common alleles and known or reported “off-ladder” microvariants, in bins, virtual bins, and also outside the ladder range.
   b. Alleles are assigned to a locus by virtue of their size and the locus-specific primer attached to the amplicon. Occasionally an allele may be detected outside of the designated range of expected alleles for a given marker. Evidence of this may be a locus with a tri-allele pattern adjacent to a locus with an apparent homozygous pattern. The errant allele may fall within a bin or fall outside a normal bin and likely would be detected in the upper or lower range of the adjacent locus. Determining the proper locus assignment of the allele may depend on allele intensities and the ability to make allele pairing.
   c. A yellow or red PQV flag will be present in the marker-specific PQV box for OVL (overlapping alleles). This indicates that a labeled peak falls within the size ranges of two neighboring markers. An attempt should be made to determine which marker the allele should fall into, but sometimes this is not possible. If the proper locus assignment of the allele cannot be determined, the locus or loci may be designated as inconclusive. Alternatively, the sample may be amplified with a different STR kit to help resolve the true locus of the allele. Any yellow or red marker-level flag in the OVL box will automatically trigger a flag in the sample-level OMR (out of marker range) box.
   d. If an allele falls above the largest or below the smallest allele of the allelic ladder or virtual bin at a locus, the allele will be designated as either greater than (> or less than (<) the respective ladder allele (e.g., 8,>15). When this designation is used, the relative size of the allele should be estimated in order to compare among samples. However, extrapolating an allele designation beyond one repeat unit from the ladder should be avoided.

3. **Allele Designation**
   a. Allele designations are assigned to sample peaks by comparison of their base pair size to those obtained from the known alleles in the Allelic Ladder. Numerical allele designations have been assigned in accordance to the recommendations of the International Society of Forensic Genetics (formerly the DNA Commission of the International Society of Forensic Haemogenetics). The GeneMapper ID-X software uses bins, which are specific regions in the electrophoretic space that define the expected sizes for each known allele from an STR locus.
   b. Rare alleles may be encountered in casework that are not represented in the allelic ladder. The Genemapper ID-X software will accurately label alleles including those not present in the allelic ladder, such as microvariant alleles containing incomplete repeats that fall within a virtual bin. Other alleles not present in the ladder or that fall outside a bin may be designated "OL" by the Genemapper software. When this occurs, the allele designation needs to be manually calculated. See "d." below.
   c. Alleles containing an incomplete repeat motif and falling within the range span of the ladder alleles, are represented by the following convention: the number of complete repeats, followed by a period, and then the number of base pairs within the incomplete repeat. For example, an allele with 18 repeats plus 2 base pairs is designated 18.2.
   d. To designate an off-ladder allele such as a microvariant that falls outside an allelic ladder bin or virtual bin, use one of the following methods: 1. Calculate the size difference between two allelic ladder alleles that bracket the OL allele. Divide the difference by the number of basepairs between those ladder alleles. Each increment approximates represents the base pair size for each increment. Add or multiply the number of increments needed to the base pair size of the smallest ladder allele to establish a size range that includes the size of the unknown microvariant. Estimate the base pair size range for the increment(s) by calculating the +/- 0.5 base pair range for the increment(s) and compare the values to the microvariant. 2. The variant allele size calculation method in DNA Box 3.2 in "Advanced Topics in Forensic DNA Typing: Interpretation".
   e. The allelic ladders and virtual bins contain many of the incomplete repeats for each marker, but some of the more uncommon micro-variants are not and will be labeled OL (off-ladder) by the Genemapper ID-X software. A yellow or red PQV flag will be present in the marker-specific PQV box for BIN if labeled peaks do not fall inside a virtual bin for a given marker. Inject these microvariants at least twice to demonstrate reproducibility of sizing for the variant.
   f. **Labeling an OL as an Allele**
      i. To label an OL as an allele, click on the peak label, then right click, and select **Rename Allele Label** followed by **Custom Allele Label**.
      ii. In the resulting dialog box, enter the allele call and click **OK**.
      iii. In the Reason(s) For Change dialog box, enter the reason for the change (e.g., microvariant), and then click **OK**.
      iv. Select the marker row with the edit and right click on the box for its GQ PQV.
g. Allele designations for samples intended for CODIS entry must conform to the Combined DNA Index System (CODIS) recommendations.

4. Evaluation of Artifacts and Non-allelic Peaks:

a. Artifacts can rise above the analytical threshold and can be observed in any locus, thus it is necessary to identify any potential non-allelic peaks prior to interpretation and comparison of the DNA data. Non-allelic peaks may be the result of the PCR process (amplification driven) or a result of the electrophoresis process (electrophoretic). Non-allelic peaks detected above the analytical threshold will be evaluated and every attempt will be made to identify the type of artifact. The verification of the artifact will be noted in the case file.

b. Amplification artifacts:

i. Stutter: A normal amplification artifact seen as a small peak a certain number of repeat units more (e.g., N+4, N+2, etc.) or less (e.g., N-2, N-4, N-8, etc.) than the parent peak, and is a generally reproducible artifact which can be compensated for in analysis of data. The largest stutter peaks observed in all loci are four bases smaller than the primary peak, N-4, with lower amounts of N+4, N-8, N-2, and N+2 occurring at certain loci as well. Stutter is more prominent under extreme overamplification conditions due to excessive amounts of amplified DNA, and may lead to stutter peaks being elevated over the set thresholds.

1. Stutter tends to follow several trends. Alleles with long stretches of the same repeat generally show greater stutter, therefore larger alleles within a locus tend to show greater stutter. Interruptions in the homologous sequence tend to decrease the amount of stutter, thus microvariants with partial repeat structures tend to show less stutter.

2. Stutter peaks are evaluated by examining the ratio of the stutter peak height to the height of the appropriate adjacent allele, and is expressed as a percentage. The height of stutter peaks can vary by locus, and longer alleles within a locus generally have a higher percentage of stutter. Maximum expected percentages of stutter for the PowerPlex Fusion 6C Loci are as follows:

e. Additionally, a stutter threshold of 2.1% is set for N+2 stutter at SE33.

ii. Peaks in a stutter position exceeding these values may indicate the presence of a low level contributor, such as in a mixture. Additionally, a true allele may co-locate at a stutter position and may not be detected as a true allele unless it exceeds the stutter threshold value for that locus. These peaks should be considered as possible true allelic peaks if the potential stutter peak height is consistent with or greater than the peak heights observed for the minor contributor (after stutter contribution in the peak has been taken into consideration).

i. **Off-scale data:** Analyzed peak heights above the optimal range may be "off-scale" in the raw data, meaning that the CCD camera may be saturated. As a result, the analyzed peak may be assigned a lower value due to smoothing and baselining functions. This can allow the relative percent stutter for an off-scale peak to appear inordinately high and cause baseline noise to be called above the analytical threshold. If the stutter peak is greater than the established cut-off and the analyzed primary peak is nearing saturation and/or has been labeled with an off-scale flag, the analyst should interpret the results with caution. Mixture samples with off-scale data should not be used when determining low level minor components. The amplified product may be diluted and re-injected to help resolve this issue.

ii. **Shoulder:** Shoulder peaks are peaks approximately 1-4 bp smaller or larger than main alleles. Shoulder peaks can be recognized by their shape; they do not have the shape of an actual peak, rather they are continuous with the main peak. As a result of poor resolution, a stutter peak may be elevated if it falls within the raised shoulder of a tailing peak. This can lead to an accentuated stutter peak height with ratios above the established cut-off. Peaks showing shoulders that are tailing due to poor resolution can be re-injected to help resolve this issue. A loss in resolution defined by broad peaks could also suggest the capillary needs to be replaced.

iii. **Non-template directed minus 'A' nucleotide addition:** This is a split peak or shoulder artifact 1 base pair less than the parent peak and is caused by the incomplete 3' extension of an additional nucleotide beyond the template amplicon by Taq polymerase. Normally this action is remedied by extending the last extension step of the thermocycling program, however, the ability of Taq to add this nucleotide to all amplicon products is dependent on the level of DNA template.

1. Amplification conditions have been set to maximize the non-template addition of a 3' terminal nucleotide by AmpliTaq Gold DNA polymerase. Failure to attain complete terminal nucleotide addition results in "band splitting", visualized as two peaks one base pair apart. This is most often seen when an excessive amount of DNA is amplified or amplification is performed under sub-optimal PCR conditions. With the exception of microvariants, the presence of peaks differing by one base pair is suggestive of this problem. Extremely over-amplified samples should be re-amplified with less template DNA. Alternatively, for samples anticipated to have higher template DNA, a longer extension time can be added to compensate for the nucleotide "A" addition.

iv. **Pull-up:** The forming of a false peak in a certain color caused by over-saturation of a true peak in another color when its fluorescence nears CCD camera saturation. As a result, this phenomenon termed "pull-up" results in small artifact peaks that appear in other colors under the true peak. Pullup follows a regular order among the dye colors and is detected as a small peak with the same sizing as the over saturated peak.

1. Spectral overlap between the dyes is normally corrected by the spectral calibration. Pullup results when the spectral cannot correct this spectral overlap, due to the over-saturation of the CCD camera by greater-than-optimal amounts of fluorescence. To distinguish pull-up peaks: the base pair size will be the same or very close between the true peak to the pull-up artifact, and the pull-up peak is the "adjacent" color. If a pull-up peak is above the minimum peak height detection threshold, it will be sized at the same size (or close to the same size) as the true peak. Pull-up can occur as a result of the following:

2. Application of a sub-optimal spectral calibration can cause pull-up. If necessary, a new spectral calibration may need to be prepared.
3. Amplification using excess input DNA can lead to off-scale peaks (see above). The spectral calibration may not perform properly with off-scale data. The amplified product can be diluted and re-injected in order to help resolve this issue.

g. Editing Artifacts

i. To label an OL as an artifact, click on the peak label, then right click and select Rename Allele Label and the Custom Artifact Label. Complete the custom artifact label dialog box, using the appropriate abbreviation from the table below, click OK.

1. In the Reason(s) For Change dialog box, enter a reason for the edit, using the abbreviations below then click OK. The reason typed into this box will appear on the electropherogram. The marker header will turn grey.

2.
I. Data for Notes

1. Duplicate sample files can be deleted from the GeneMapper ID-X project, but all collection files are maintained electronically in the run folder. Printouts of the GeneMapper ID-X electropherograms for all samples being reported as well as corresponding substrate controls (if applicable) are to be included as part of the case packet. Printouts of the amplification positive and negative controls, QC sample, reagent blanks, allelic ladders and WEN ILS standards are not necessary for the case packet. These will be reviewed electronically during technical review.

2. Multiple amplification and/or injections: All data is kept in the electronic run folder including data not used for analysis or interpretation. In the event that a sample has undergone multiple amplifications or injections, the analyst will use the result or combination of results with the most genetic information for comparison and statistical calculations. The sample(s) used for interpretation must be printed out for the case file. When DNA results across the different loci from multiple injections or amplifications of the same sample are assembled for a profile for interpretation and comparison, the profile is considered a composite profile and will be labeled as such.

J. Saving the Project

1. The GeneMapper ID-X project must be saved prior to exporting. To save the project, select File>Save Project As and use the naming convention mentioned previously. If the project is closed prior to saving, GMIDX will automatically prompt with, "Do you want to save changes?". Click "Yes"

K. Exporting the Project

1. After analysis is complete, export the project by opening Tools>GeneMapper Manager, select the project to export and click the Export button. Export the project to its corresponding case folder in the appropriate Run Folder on the laboratory's internal network drive.

L. Creating the Data Summary Table.

NOTE: Summary Tables will only be created for cases where interpretation using binary methods is performed.

1. Refer to the instructions contained in the excel workbook "Fusion Summary Sheet".

M. Documenting Results on the Summary Data Sheet

1. The Summary Data Sheet will contain, at a minimum, the analyzed DNA results from all references and evidence samples. These results will be interpreted, and from the interpretation, a conclusion will be drawn, when applicable.

2. One sample row will contain the raw data. Another sample row should be created when the analyst is able to interpret a major or minor contributor's profile.

3. Symbols may be used on the Summary Data Sheet. The following symbols may be used:
   a. +, will be used to denote an obligate allele for CODIS searching.
   b. * or _ will be used for single source samples and deduced major/minor contributors to indicate a single peak below the stochastic threshold. This should be added after a single STR allele that is below 600 RFU to indicate that the sister allele at that location may have dropped out.
   c. Other symbols used on the summary sheet will be noted with a brief comment about their meaning.

4. On occasion, an analyst may be unable to differentiate a peak as an allele from an artifact (e.g., electronic noise, dye blob, spikes, stutter, pullup, etc.). The analyst may label this peak a “possible allele” and also document it on the summary data sheet as “poss” followed by the allele designation. An explanation in the case notes must be given that describes why the allele is inconclusive.

5. A separate line in the Summary Data Sheet may be filled out for any CODIS profiles. The DNA data in a CODIS profile may appear differently than the deduced profile, due to the searching algorithms of CODIS. A separate tab in the Fusion Summary

workbook, may be filled out to indicate any profile(s) that will be entered into the CODIS database. If a profile is to be entered into CODIS, the CODIS Eligibility sheet of the Fusion Summary Sheet must be filled out to include the following information:

a. A justification for why the profile is eligible to be entered into the database
b. The unique specimen name (exactly how it will be entered into CODIS)
c. The category in which it will be entered into CODIS (e.g., forensic unknown, mixture, etc.)
d. The agency and their case number
e. The offense date
f. If an elimination sample is needed and the request date

N. Performing QC Profile Comparisons on Sample Results

1. The profile comparison tool does the following for all samples in a project:
   a. Groups samples with 100% concordant profiles.
   b. Compares samples within the project against all other samples in the project.
   c. Compares samples in the project against lab references, custom controls and QC sample profiles stored in the Profile Manager.

2. It is important to evaluate samples and edit allele labels to ensure there are no OLs present before running the profile comparison tool because samples containing OL labeled peaks are not considered in comparisons.

3. To run the sample comparison tool, select Tools > Profile Comparison. The Profile Comparison tool opens to the Sample Concordance tab. This lists any samples with 100% concordance. Click the + sign to expand the samples view.

4. Click on the Lab Reference Comparison tab. Keep the Percent Match Threshold at 90%, then click Compare Profiles.

5. Review the results. This will list any lab reference samples that have profiles that meet the 90% match threshold.

6. Importing Lab Reference and Custom Control Profiles
   a. Before adding lab references and custom control samples to GeneMapper ID-X, the samples must be reviewed and all artifacts/OLs must be edited.
   b. From the Table Setting drop-down list, select Import Reference Profiles
   c. Highlight a sample in the samples tab
   d. In the Profile ID column of the Samples tab, enter the Reference samples unique Profile ID number
   e. Select Tools>Add Profile>Lab Reference or Tools>Add Profile>Custom Control
   f. Click Close
   g. In the Project window, select Tools>Profile Manager, you can view the genotypes stored in the GeneMapper ID-X database for each lab reference and custom control sample.

*Alleles in red will need to be designated as "<the lowest" or " the highest CODIS ladder designation for CODIS entry*
I. Analysis and Evaluation of Identifiler Data

A. Preliminary Evaluation of Data:

1. DNA Data detected by the Genetic Analyzer is routinely evaluated for the following conformance:

   a. **Resolution:** The electropherogram must have adequate resolution to provide clear separation of alleles. Resolution is inspected with each electropherogram. All peaks must display sharp, distinct beginning and ending arms. Poorly resolved peaks generally require re-injection. Loss of resolution can be linked to a single bad electrokinetic injection, in which case the sample can simply be re-injected. The loss of resolution may be linked to a failing capillary, in which case the capillary should be replaced and the samples re-injected.

   b. **Signal Intensity/ Relative Fluorescent Unit:** When excited by the laser, the fluorescent dye tags incorporated into the DNA primers emit a characteristic color of light. The amount of light emitted is quantitatively analyzed by the Genetic Analyzer's CCD detector, and this response is shown on the Y axis of the resulting electropherogram in relative fluorescent units (RFU.) The 310 Genetic Analyzer has a maximum response of 8191 RFU.

      Ideally, analyzed DNA peaks are detected in the range of 1000 to 3500 RFU. Empirical data from validation studies show this range provides the best balance of allele heights, between and within loci, with a minimum of artifacts. This signal intensity is in part related to the input level of DNA for amplification, which is optimized between 0.75ng and 1.5ng at 28 cycles. Validation data also shows reproducible and accurate results for data outside this "optimal" range, with input as low as 0.25ng resulting in responses as low as 200 RFU providing reproducible genotype results depending on the quality of the DNA.

   c. **Peak Height Imbalance:** Heterozygous peaks within a locus generally display peak height ratios (lower height divided by higher height x 100) of 60% or greater. Peak height ratios less than 60% may indicate alleles from two separate sources (i.e. mixtures), or could be the result of stochastic effects or poor amplification, or more rarely, a tri-allelic pattern, or a primer site mutation.

B. Guidelines for assessing Signal Intensities:

1. **Input DNA:**

   a. The optimal level of input DNA is 0.75 - 1.5 ng per amplification. Acceptable amplification has been obtained with input levels as low as 0.25 ng of total human DNA when the DNA is of good quality (non-degraded or inhibited). Resolution of mixtures of two or more sources of DNA may require slightly higher input levels, such as 1.5 to 2.0 ng to adequately detect each donor. In cases of degraded DNA, excess template addition (>2.0 ng) has resulted in successful amplification.

2. **Fluorescence Intensities:**

   a. **Analytical Threshold:** Based on validation data, the minimum peak height threshold is 50 RFU. While peaks can be observed below 50 RFU and may indicate the presence of a true allele, peaks below 50 RFU will not be registered as alleles for reporting purposes.

   b. **Stochastic Threshold/Trace level DNA:** Peaks can readily be designated as alleles in the 50 to 200 RFU range; however stochastic fluctuations are known to occur at this level (i.e. a known heterozygote can be misinterpreted as a homozygote). It is highly recommended that samples showing such low amplification be injected and analyzed in duplicate to demonstrate reproducible allele calls.

      i. For samples with low input levels of DNA several measures can be used to enhance detection sensitivity. Two measures an analyst can use are increased injection time and post amplification purification.

      ii. A sample may be re-injected for an increased injection time in an effort to increase peak heights above the analytical threshold. Any corresponding negative and substrate controls must also be re-
C. Evaluation of Internal Size Standards and Allelic Ladders:

1. The sizing of amplicons is conducted by comparing the unknown amplified DNA amplicons to an internal size standard consisting of DNA fragments of known size. The internal size standard is referred to as GS 500 and is a plasmid derived series of LIZ labeled DNA fragments of known size. The internal size standard is added to each amplified sample, including the allelic ladder. To size the unknown amplified amplicons, the amplicons are compared to the DNA fragments contained within an allelic ladder which has also been sized against the internal size standard. The designation of alleles is dependent on the precise sizing of each of the DNA amplicons.

2. An Allelic ladder is prepared and required to be injected with each batch of injected samples within a designated ABI 310 run. QAS 9.5.4. When sized, using the internal size standards, the allelic ladder(s) provide the means for assigning allele designations to the amplified products in each sample. Allelic ladders are evaluated in GeneMapper to assess the following:

   a. Adequate peak height (generally 500 to 3000 RFU)
      Appropriate peak resolution
      Correct range (minimally, the 75 through 450 base pair peaks should be recorded for Identifiler.)
      Presence of each declared GS 500 peak for the sample.

   b. Each of these artifacts can affect interpretation depending on the degree of over-saturation. The presence of these artifacts does not preclude interpretation of the sample, provided that the examiner can qualify the anomalous results as artifacts. (For instance, in a sample with no other indication of a mixture in which an anomalous blue peak coincides in sizing to an over-saturated green peak, the examiner would be justified in discounting the anomalous blue peak as pull-up.) Active measures the examiner may take to address artifacts caused by over-amplification include dilution of the amplified product and re-injecting, re-amplification at a lower amount of template DNA or re-injection at a lower injection time.

   c. Low Level DNA: DNA detected between 200 RFU and 500 RFU is considered low level DNA. Based on validation studies, it is reasonable to assume that at a given locus, allelic dropout of a sister allele has not occurred when DNA is detected above the 200RFU Stochastic Threshold. However, occasional random peak imbalances (i.e. known paired heterozygous alleles displaying less than a 60% peak height ratio) were noted among samples across most loci at this signal intensity. This variation appeared to be amplification mediated as the imbalance was not reproducible between duplicate amplifications. The 60% peak height ratio is one parameter considered in assessing mixtures, and more importantly, in assessing paired alleles in mixtures. Additional caution should be used in assigning major and minor contributor types in mixtures at this intensity level.

   d. Optimal Level DNA: Analyzed data values detected in the 500 to near 5000 RFU range provides adequate data for most interpretations, however peak height balance and balance between loci with minimal amplification artifacts are best displayed between 1000 and 3500 RFU.

   e. Saturated DNA Level: Analyzed Data detected between the 5000 to ≥8100 RFU will begin to exhibit symptoms of oversaturation. Peaks displaying values greater than 8100 RFU have exceeded the dynamic range of the CCD camera. Oversaturated data can lead to one or more of the following undesirable artifacts:
      i. Pull-up peaks in the nearest spectral color adjacent to the saturated color.
      ii. Anomalously high stutter peaks relative to the saturated peak.
      iii. Incomplete nucleotide addition termed (-A) or (INA).

   f. Each of these artifacts can affect interpretation depending on the degree of over-saturation. The presence of these artifacts does not preclude interpretation of the sample, provided that the examiner can qualify the anomalous results as artifacts. (For instance, in a sample with no other indication of a mixture in which an anomalous blue peak coincides in sizing to an over-saturated green peak, the examiner would be justified in discounting the anomalous blue peak as pull-up.) Active measures the examiner may take to address artifacts caused by over-amplification include dilution of the amplified product and re-injecting, re-amplification at a lower amount of template DNA or re-injection at a lower injection time.
a. Adequate peak height (generally above 200 RFU)
  Appropriate peak resolution
  Absence of anomalous peaks such as spikes
b. Allelic ladders will be inspected to verify that each intended allele is present and called. The technical reviewer will also verify the Allelic ladder(s).

D. Evaluation of the Amplification Positive Control and the Quality Control Sample:

1. An amplification positive control is required to monitor that the amplification and typing process worked properly. Because the positive control is amplified concurrently and analyzed with the evidence set, the amplification positive control (9947A) in the Identifiler kit serves as a verification that the amplification conditions used to amplify the evidence samples performed as expected. The correct DNA profile for the 9947A must be obtained across all loci and the alleles must be adequately amplified (>200 RFU).

2. An optional positive extraction control (quality control sample) of known DNA type may be added with the extraction sample set. Because the QC sample is extracted and typed concurrently with the evidence set, it serves to monitor that the procedures worked properly from extraction through typing. The correct DNA profile of the quality control sample must be obtained across all loci and the alleles must be adequately amplified (>200 RFU).

3. If either of the positive controls do not provide the expected results, an investigation into the root cause needs to be conducted. If the cause is deemed to be due to analyst error and not a problem with the amplification process itself, the analyst should take steps to troubleshoot and correct the problem. If the root cause is due to improper performance of equipment, reagents or supplies, the DNA Technical Lead and/or Supervisor must be immediately notified to prevent further potential detrimental DNA results. In both cases, the reliability of the DNA typing results will be evaluated. If the corrective measures taken correct the problem and it can be demonstrated that the results are reliable in spite of the performance issues, the results may still be reported. The analyst will document the performance issue using a Level II Quality Incident Report form or equivalent to describe how the performance issue was corrected and how the results are considered reliable and valid.

When a result cannot be reported, it will be conveyed in the lab report with a brief description of the reason. A level III Corrective Action (see FSD.15) will document the problem, investigation, corrective measures taken, the result/resolution, cause and prevention. A copy of the Corrective Action will be placed in the case notes or reference to the Corrective Action in LIMS will be documented in the case notes. The Unit Supervisor and DNA Technical Lead will review the Corrective Action and have the discretion to determine the appropriate course of action. See Corrective Action Policy BIO.5.QAQC.14.

E. Evaluation of Negative Controls that Monitor for Contamination:

Negative controls are designed to test for unintentional introduction of exogenous DNA into the reagents or sample. Each negative control monitors for DNA contamination during different procedural steps.

1. A **reagent blank** is required for each extraction set. The reagent blank is carried through the extraction, concentration, quantification, amplification and typing process, therefore it serves to monitor for all reagents and consumables utilized, as well as the set-up environment of each process. The reagent blank should contain no detectable DNA at the most sensitive analysis conditions used to analyze the evidence set, such as at the lowest analysis threshold or the highest injection time used and at the most concentrated level.

2. An **amplification negative control** is required for each amplification set-up. The negative control monitors for DNA contamination of the PCR Kit reagents and PCR set-up environment. The negative control should contain no detected amplified DNA at the lowest analysis threshold used to analyze the associated evidence set.

3. If DNA contamination (genomic or amplified DNA) is detected in the reagent blank (RB) or negative control, an investigation into the root cause and source of the contamination needs to be conducted. If the DNA detected in the RB or negative control is due to sample process handling, such as a sample switch, sample or PCR product carry-over, or the analyst's DNA, the analyst will take steps to re-trace where the problem occurred and correct the problem. If the contamination is suspected to be due to contaminated consumables, the set-up environment, manufacturer's reagents or factors beyond the analyst's control, the analyst will attempt to identify the source and correct the problem, where possible.

4. To correct the problem and to confirm that the results are reliable for reporting, repeating one or more of the set-up steps, such as the CE set-up, re-amplifying the affected samples, and/or re-extraction of the evidence material may be required. If the corrective actions taken correct the problem and demonstrate that the results are reliable, then the results may be reported. The analyst will document the contamination event using a Level II Quality Incident Report form or equivalent to describe how it was corrected and how the results are considered reliable and valid.

If the PCR kit reagents are suspected to be contaminated, the samples should be re-amplified utilizing a new STR...
kit. (Note: If the contamination in the negative control is due to the PCR Kit reagents, contamination would also be expected to be observed in the reagent blank.)

5. If the analyst cannot correct the problem because sample no longer remains to repeat the analysis, or, if at the analyst's discretion the analyst chooses not to repeat the analysis, the analyst must demonstrate that the DNA results are reliable and valid in spite of the contamination. This must be demonstrated prior to reporting the results. Results may be reported if the analyst can demonstrate that the contamination event meets any of the following:

a. The unexpected DNA/DNA profile observed in the reagent blank/negative control is not observed in the evidence sample(s), or the unexpected DNA does not account for the genotypes/profiles observed in the associated evidence sample(s).

b. The unexpected DNA/DNA profile is observed in RB/negative control and the evidence sample, however the detected level (quantity) of unexpected DNA in the control could not account for the detected level (quantity) of DNA in the evidence sample(s) or for the interpreted component of a DNA mixture.

c. A second RB associated with the same evidence set demonstrates that the laboratory's reagents are not contaminated.

All contamination events will be documented in the case notes. The analyst will document the problem, investigation, corrective measures taken, the result/resolution, cause and prevention, when applicable, and justify the reasons why the results are reliable using a Level II Quality Incident Report form or equivalent. A copy of the Quality Incident Report will be placed in the case notes and in the Analytical Controls Log.

In the event the analyst cannot demonstrate the results are reliable, the results will be deemed invalid and the result(s) will not be reported. When a result cannot be reported, it will be conveyed in the lab report with a brief description of the reason. A level III Corrective Action (see FSD.15) will document the problem, investigation, corrective measures taken, the result/resolution, cause and prevention. A copy of the Corrective Action will be placed in the case notes or reference to the Corrective Action in LIMS will be documented in the case notes. The Unit Supervisor and DNA Technical Lead will review the Corrective Action and have the discretion to determine the appropriate course of action.

F. Designation of Alleles:

1. Peaks are distinct, reproducible, triangular projections above the baseline of the electropherogram. Analyzed peaks appear as a single color with distinct beginning and ending branches at the baseline. Peaks varying by at least 2 basepairs can readily be resolved from other peaks at the baseline. A peaks 1 basepair apart (i.e. a 9.3, 10 combination) rests on either the beginning or ending shoulder of its neighboring peak. The peak may appear as a hump or shoulder on the side of its neighboring peak because peaks 1 basepair apart cannot be individually resolved as a single peak down to the baseline.

2. Locus Assignment:

a. Locus assignment is performed through GeneMapper software. The software defines the range of expected alleles for a given locus which is portrayed as a gray box in the electropherogram plots. Loci labeled with the same color dye tag do not have overlapping sized alleles.

3. Allele Designation:
An allele is a variation/form of DNA at a particular site on a chromosome. For purposes of determining whether a peak is an allele, the allele must meet minimum standards for analysis such as resolution and signal intensity.

a. Whenever possible, allele designations will be based on the number of repeat sequences contained within the allele. Alleles will be assigned based on comparison to the accepted Allelic Ladder.

b. The designation of alleles containing an incomplete repeat motif (i.e. an off-ladder allele falling within the range spanned by the ladder alleles) will be designated by the number of complete repeats, a period, and then followed by the number of base pairs in the incomplete repeat (e.g. FGA 18.2.)

c. Uncommon micro-variants (i.e. uncommon alleles, differing by 1 to 3 base pairs from the common motif, and not present in the allelic ladder) should be injected at least twice to demonstrate reproducibility of sizing for the variant.

d. If an allele falls above the largest or below the smallest allele of the Allelic Ladder, the allele should be injected at least twice to demonstrate reproducibility of sizing for the variant.

e. Allele designations for CODIS entry conform to the Combined DNA Index System (CODIS) recommendations.
4. Designation of artifacts:
Artifacts are a phenomena observed in electropherograms that can complicate interpretation. Artifacts can be either amplification mediated or electrophoretic mediated.

a. Amplification artifacts:

i. Stutter: A normal amplification artifact seen as a small peak one tetranucleotide repeat unit (N-4) less that the parent peak, and is generally a very reproducible artifact which can be compensated in analysis of data. The most common stutter peaks observed in all loci are four bases smaller than the primary peak ("n-4"). Under extreme overamplification conditions, due to excessive amounts of amplified DNA, stutter peaks may be observed at N-8 and N+4 repeats. Stutter, caused by repeat slippage during amplification, tends to follow several trends. Alleles with long stretches of homologous repeats generally show greater stutter, therefore larger alleles within a locus tend to show greater stutter. Interruptions of the homologous sequence tend to decrease the amount of stutter, thus micro-variants with partial repeat structures tend to show less stutter.

ii. Stutter peaks are evaluated by examining the ratio of the stutter peak height to the height of the appropriate adjacent allele, expressed as a percentage. The height of stutter peaks can vary by locus, and longer alleles within a locus generally have a higher percentage of stutter. Maximum expected percentages of stutter for the Identifiler Loci are:

b. Peaks in a stutter position greater than these values may indicate a true allele, such as in a mixed sample. Stutter peaks can also be elevated above established thresholds due to the following:

i. Analyzed peak heights above the optimal range may be "off-scale" in the raw data, meaning that the CCD camera may be saturated. Peaks with a height of 8191 RFU are off-scale. However, the analyzed peak may be assigned a lower value due to smoothing and baselining functions. This can allow the relative percent stutter for an off-scale peak to appear inordinately high. If the stutter peak is greater than the established cut-off and the analyzed primary peak is nearing or above 5000 RFU and/or has been labeled with an off-scale flag, the analyst should interpret the results with caution. To correct, the amplified product may be diluted and re-injected to help resolve this issue.

ii. As a result of poor resolution, a stutter peak may be elevated if it falls within the raised shoulder of a tailing peak. This can lead to an accentuated stutter peak height resulting in ratios above the established cut-off. Peaks showing shoulders that are tailing due to poor resolution can be re-injected to help resolve this issue.

iii. A stutter peak falling in an area where the baseline is elevated may exhibit an accentuated peak height and thus an accentuated stutter percentage. Elevated baselines may indicate an improperly functioning matrix. Stutter peaks can also reside in the pull-up of an adjacent color allele. The analyst may choose to apply a different matrix or dilute and re-inject the sample to help resolve this issue.

iv. Non-template directed minus 'A' nucleotide addition: This is a split peak or shoulder artifact 1 base pair less than the parent peak and is caused by the incomplete 3’ extension of an additional nucleotide beyond the template amplicon by Taq polymerase. Normally this action is promoted by extending the last extension step of the thermocycling program, however the ability of Taq to add this nucleotide to all amplicon products is dependent on the level of DNA template.

Amplification conditions have been set to maximize the non-template addition of a 3’ terminal nucleotide by AmpliTaq Gold DNA polymerase. Failure to attain complete terminal nucleotide addition results in "band splitting", visualized as two peaks one base pair apart. This is most often seen when an excessive amount of DNA is amplified or amplification is performed under sub-optimal PCR conditions. Except for microvariants, the presence of peaks differing by one base pair apart is diagnostic of this problem. Extremely over-amplified samples should be re-amplified with less template DNA. Alternatively, for samples target and anticipated to have higher template DNA, a longer extension time can be added to compensate for the nucleotide "A" addition.

v. Pullup: The forming of a false peak in a certain color caused by over-saturation of the true peak when its fluorescence nears or is ≥8100 RFU. As a result, this phenomenon termed "pull-up" results
in small artifact peaks that appear in other colors under the true peak. Pullup follows a regular order among the dye colors and is detected as a small peak with the same sizing as the over saturated peak.

Spectral overlap between the dyes normally is corrected by the matrix. Pullup results when the matrix cannot correct this spectral overlap, due to the over-saturation of the CCD camera by greater-than-optimal amounts of fluorescence. To distinguish pull-up peaks: the data point (sizing) will be the same or very close between the true peak and the pull-up artifact, and the pull-up peak will be the "adjacent" color. If a pull-up peak is above the minimum peak height detection threshold, it will be sized at the same size (or close to the same size) as the true peak. Pull-up can occur as a result of the following:

1. Application of a sub-optimal matrix can cause pull-up. If necessary, matrix standards can be prepared after the analytical run and a new matrix can be created and applied.
2. Amplification using excess input DNA can lead to off-scale peaks (see above). The matrix may not perform properly with off-scale data. The amplified product can be diluted and re-injected to help resolve this issue.

d. Electropherogram artifacts:

   i. In addition to amplification artifacts described above, the following anomalies can arise during electrophoresis and analysis:

   1. Significant room temperature fluctuation may cause sizing variations between injections such that Allelic Ladder peaks differ by more than 0.5 bp from allele peaks in other injections. This will cause GeneMapper to assign these alleles as off-ladder alleles. Genotyping with a different Allelic Ladder injection may correct this problem. If desired, the sample(s) and the Allelic Ladder may be re-injected to confirm the typing.
   2. Non fluorescent tag derived peaks. Occasionally non-allele based peaks are observed in electropherograms. Sometimes referred to as "blobs" or "dye artifacts", the size and broad shape of these artifacts provide a means to distinguish them from true alleles. A higher analysis parameter can be applied to analyze the data, when possible, to remove artifacts.
   3. Electronic noise. The electropherogram may show very narrow "spikes" of various heights. These do not have a true peak shape, and often are represented in multiple colors at the same data point. Sometime a spike can be present in a single color. When the peak has been determined to be an artifact, a higher analysis parameter can be applied to analyze the data, when possible, to remove the artifact.
   4. Baseline fluctuation: This artifact of the electropherogram response is a normal variation seen at very low relative fluorescent levels. Fluctuations are generally corrected to levels below 50 RFU, however occasional raised baselines in a single color are observed.

G. Documenting Results

1. The amplified DNA results will be captured in the case notes and will be listed on a Summary Data Worksheet. The Summary Data Worksheet will contain, at minimum, the analyzed DNA results from all references and evidence samples. These results will be interpreted, and from the interpretation, a conclusion will be drawn, when applicable.

2. Typically, the standard 5-second injection is used for interpretation. When an injection time other than the standard 5-second injection is used for the interpretation and for the reporting of a conclusion, the DNA results from the altered injection will be displayed on the Summary Data Worksheet. The sample name will include the altered injection time (i.e 3 sec or 10 sec) to indicate the DNA results are from an altered injection time.

3. If post-amplification purification was performed, the sample will be labeled with "post" to indicate the results are from a post-amplification purification. The Summary Data Worksheet will display both the standard 5-second injection results as well as the post-amplification results, if the post-amp results are being used for interpretation and reporting a conclusion.

4. One sample row (optional) may be displayed to capture the analyst's assessment of the data. This row is not an interpretation of the data but an assessment of the results and its qualities, such as peak heights, peak height imbalances, and stochastic range alleles:
   a. The > symbol can be used to denote peak height balance (imbalance) of less than 60% either between two alleles or a set of alleles within a locus. Peak height balances between 55% and 59% may be denoted as > to convey that the peak height balance is approximately 60%. This symbol typically is only useful with two-person mixtures when denoting alleles attributable to the contributors in the mixture.
   b. Brackets "[ ]" are used to document low level alleles that are within or are nearing the stochastic threshold range. This means that there is the potential that one of the alleles from a heterozygous pair could have
dropped below the analytical threshold (below detection). Alleles that are below the stochastic threshold (200 rfu) but above the analytical threshold (50 rfu) will be placed in brackets on the data summary sheet. Alleles that are slightly over the stochastic threshold could have drop out; therefore, caution is needed for those alleles nearing the stochastic threshold. Bracketing alleles that are over but near the stochastic threshold is at the analyst's discretion.

c. On occasion, an analyst may be unable to differentiate a peak as an allele from an artifact (electronic noise, dye blob, spikes, stutter, pullup, etc). The analyst may call this peak a “possible allele” and it will be documented on the summary data sheet as “poss” followed by the allele designation. An explanation in the case notes will be given that describes why the allele is inconclusive. When a peak is called/labeled under enhanced run conditions, such as a 10 second injection or post-amplification purification, but the peak is not detectable above the baseline in the standard run condition, the peak will be reported as a possible allele. Possible alleles will not be used for interpretation purposes.

5. At least one sample row should be created when the analyst is able to interpret a major or minor contributor's profile or a deduced mixture profile.

6. A separate row, typically at the bottom of the Summary Data Sheet, will be created to indicate any profile(s) that will be entered into the CODIS database. The DNA data in a CODIS profile may appear differently than the deduced profile due to the searching algorithms of CODIS. If a profile is to be entered into CODIS, the top portion of the Summary Data Sheet must be filled out to include the following information:
   a. A justification for why the profile is eligible to be entered into the database
   b. The unique specimen name (exactly how it will be entered into CODIS)
   c. The category in which it will be entered into CODIS (forensic unknown, mixture, etc.)
   d. If the source of the profile has been identified
   e. The agency and their case number
   f. The offense date
   g. If an elimination sample is needed and when it was requested

H. Interpretation

1. Single Source Profiles
   When the DNA data represented in a full 15 locus profile contains no more than two alleles at each locus and each allele pair within a given locus is balanced within expectations, it is highly probable the DNA results are attributable to a single contributor. Exceptions to the two allele maximum per locus are persons with a triallele genotype.

Any sample that exhibits less than a complete 15 locus profile is considered a partial profile. Partial profiles can result from degraded or inhibited samples or samples which contain a primer binding site mutation or samples originating from low quantity. A partial profile contains less genetic information for assessing the potential number of contributors in the sample, therefore additional caution is needed when determining whether the observed DNA has originated from a single contributor. Single source partial profiles, while expressing less genetic information than a full fifteen locus profile, still can provide useful information for purposes of inclusion and exclusion.

For all single source samples, full or partial, the genotypes of the individual are readily discernable at each locus. An individual may be included as a possible source of the DNA when the sample matches across all the interpreted loci to the loci observed in the reference.

1. Typically a Random Match Probability (RMP) statistic is applied to a single source sample. (See Statistics section below)

2. For a single source profile, where any of the loci contain a single allele and the single allele is in the stochastic range (<200 rfu), the \( f = 2^*p^*(1- p) \) formula should be applied to calculate the genotype frequency of that allele.

2. Mixture Interpretations:
   The interpretation of mixtures is complex and no single expression may clearly convey the information in a mixed sample. The assessing of mixtures involves evaluation of all the loci for the presence of more than two alleles within one or more loci, and the presence of allele pairs that show peak height imbalance. While allele pair imbalances alone could indicate a mixture, there may be other causes for peak height imbalances besides mixtures, such as stochastic effects due to low input DNA and/or amplification, and primer site mutations leading to differential amplification.

Steps to evaluating a mixture:
a. Characterize the quality of the amplification
   i. Describe the objective signs of degradation and/or inhibition evident in the sample and overall quality of the sample.
      1. Quantitatively describe the overall level of amplification (well, moderate or poor amplification) of the sample based on the overall allele heights or the sum of allele heights.
      2. Identify those loci for which quality issues suggest that complete or partial drop out is possible due to loci with stochastic level alleles.
      3. Identify those loci for which quality issues limit assessing the potential number of contributors in the mixture due to potential drop out of alleles.
      4. Identify those loci that no longer are useful for elimination purposes and remove these uninformative loci from further consideration.

b. Identify that a mixture is present
   In general, the presence of more than 2 alleles at multiple loci, or in combination with peak height imbalance, is an indicator that a mixture is present. (Rare tri-allelic patterns due to trisomy, unequal crossover, gene duplication, or somatic mutation (mosaicism) can display three allele patterns at a single locus.)
   i. Identify loci with more than 2 alleles (artifacts are assumed to have been addressed)
   ii. Evaluate whether the intensity variation between alleles is inconsistent with single source. In general, PHR's <60% can be a indication of a mixture however this is also dependent on the quality of amplification.

c. Determine the number of contributors or the minimum number of contributors. Consider the number of alleles at any one locus and evaluate peak height imbalances between alleles.

d. Consider and factually describe known information from which reasonable inferences can be assumed about the sample.
   i. Intimate Samples- the donor of the sample can be assumed to be present in the sample
   ii. Proximal Evidence-an unknown DNA profile may be assumed to be potentially observed elsewhere on other closely related evidence
   iii. Given the case circumstances or the location of the collected evidence, there may be a high potential for related individuals to be part of the mixture

e. Characterize the DNA contribution ratio of each contributor in the mixture, if possible.
   i. Separate and identify any clear major contributor profile from any minor contributor profile(s).
   ii. For samples where a 2-person mixture has been determined, consider deconvolution of contributors in the mixture (consider using Least Squares Deconvolution)
   iii. When possible, use factual information to apply inference regarding the presence of at least one of the contributors in the mixture
   iv. Consider the quality of the DNA results and how it affects the interpretation of ratios overall. Evaluate whether the ratios remain constant across the loci (even under degrading conditions) or is there evidence of differential degradation between the contributors.

f. Assign genotypes to the major, minor, or to the mixture component, where possible.
   The extent to which a major or minor donor profile can be interpreted from a mixture is dependent on factors such as whether a supported factual assumption can be made about one or more of the contributors in the mixture (i.e. intimate or proximal contributors). The complexity of the mixture may limit or prohibit complete or even partial interpretation of the donors (i.e. indistinguishable 3 or more person mixture where no single profile can be deduced or assumed). Quality issues, such as stochastic level allele limit or prohibit complete or partial interpretation of the mixture due to the potential for missing genetic information.
   i. Mixtures displaying distinguishable major and/or minor contributors at all loci:
      In some mixtures, the relative proportions of the donors are such that the genotype of individual profiles can be easily distinguished at all loci. A sample which displays a distinct difference in signal intensities between alleles may be classified as a mixture with major and minor contributors. When
In other mixtures, the genotypes may need to be "deduced" from the mixture when there is not a readily clear profile of the major or minor contributor. Deduction of the contributor's profile may be possible at all 15 loci or may only be possible at some loci resulting in a partially profile.

An allele potentially located in the same location as a stutter peak may not be detected as a true allele if the total RFU does not surpass the stutter percentage. Stutter peaks should be considered as possible allelic peaks when the stutter peaks are at heights consistent with or greater than the minor contributor peaks. Contribution of stutter to the overall peak height needs to be taken into consideration when determining potential minor contribution to the stutter peak. A 2p frequency calculation may need to be applied to the minor allele after stutter contribution has been taken into consideration if the remaining overall height of the peak at a stochastic level.

When a single genotype profile or a deduced single genotype profile of the major or minor contributor can be distinguished at each interpretable loci, the individual profile is calculated using RMP in the same way as a single-source profile.

ii. Mixtures composed of a set of selected loci:

In mixtures where the individual donor profiles cannot be deduced to a set of single genotypes at all loci, a "set of genotypes" may be assigned to one or more of the individual donors in the mixture. This approach assumes a single major or minor contributor and that the major or minor profile is contained within the set of alleles detected at each locus as either a distinct allele, a masked allele or within a stutter artifact. Deduction of the contributor's profiles may be possible at all 15 loci or may only be possible at some loci resulting in a partially deduced profile.

Assignment of the set of genotypes at each locus requires derivation/deconvolution or subtraction of other components/contributors in the mixture. When all possible genotypes have been deduced at each locus, the frequency of each genotype is summed and calculated using Modified RMP. Deduction of the contributor's profile may be possible at all 15 loci or may only be possible at some loci resulting in a partially deduced profile.

A "set of genotypes" can be assigned to a mixture profile when the number of contributors in the mixture or in the interpreted component of the mixture (i.e. major component) can be defined and the quality of the DNA results supports that all of the DNA from the defined number of contributors can be accounted for in the mixture (i.e. complete drop of any one contributor has not occurred). A complete mixture profile or a partial mixture profile may result from the interpretation and is dependent on the complexity and quality of the DNA results.

An alternate statistical approach to assessing a mixture is the Combined Probability of Inclusion or CPI. CPI does not rely upon distinguishing individual donors into major or minor contributors, nor does it necessarily require an assumption of the number of contributors. The CPI module calculates the frequency of "every" possible genotype combination at a given locus based on the set of alleles detected at that locus. As a result, the frequency of the set of genotypes at each locus are summed and each locus is multiplied. CPI assumes each of the donors are represented in the set of alleles detected, therefore CPI requires good amplification of each of the contributors in the mixture (i.e. no drop out). In most cases, CPI can only be used for well amplified mixture samples, typically consisting of no more than 2 to 3 donors. The following is the CPI formula:

\[
f = \left( p_1 + p_2 + \ldots + p_k \right)^2 \text{ where } p_1 + p_2 + \ldots + p_k \text{ are the frequencies of the alleles detected at the locus, and } k \text{ is the number of alleles. The frequencies determined for each locus may then be incorporated into the product rule.}
\]

i. Mixtures with known contributors:

In some mixtures, one or more of the DNA donors to a sample is known or can reasonably be assumed to be present (for example, the female contribution to a vaginal swab.) The genetic profile of the unknown contributor may be deduced by subtraction or deconvolution using the known contributor's profile. If a single source profile is deduced, the frequency for the unknown profile is calculated using RMP. If a "set of genotypes" is deduced, the frequency for the unknown profile is calculated using Modified RMP.

iv. Mixture with indistinguishable contributors:

Indistinguishable mixtures where there is no clear single discernable profile are often obtained from mixtures of 3 or more contributors. Inclusions and exclusions may still be made based on the presence or absence of detected alleles. If a mixture component profile also cannot be deduced, then
I. Conclusions based on Interpretation of Results:

The following conclusions are used to address comparisons between casework questioned samples and reference samples:

a. Exclusion (Elimination): A person will be reported as being "excluded" when the sample has one or more non-matching alleles when compared to the reference source. The result should be reported as "could not be the donor of the questioned stain" or similar wording.

b. Inclusion (match): A person will be reported as "included" when the sample matches across all interpreted loci when compared to the reference source. The result should be reported as "included as a potential donor of the questioned stain" or similar wording. Inclusions will be qualified with a statistical analysis of the estimated frequency of occurrence of the questioned stain profile (see statistical analysis below.)

c. Uninterpretable/Inconclusive: A conclusion of "uninterpretable or no conclusion" is reported in situations when the DNA results are below interpretable levels, or much of the interpretable component is at stochastic levels or with confounding complex mixtures (mixtures of 3 or more persons with much of the genetic information at stochastic levels). An inconclusive finding will be reported when the genetic information contained in the DNA results is insufficient to include or exclude the reference source as the donor of or contributor to the questioned sample.

d. No results: A conclusion of "no result" is reported when no amplified DNA has been detected above the analytical threshold at all loci.

J. Statistics

1. Statistical interpretations provide an objective means to assess the strength or significance of an inclusion (match). All inclusions of a probative nature will have a statistical interpretation provided. Statistical calculations are not required to support the inclusion of an individual on his or her own intimate sample. An intimate sample is any sample where there is a reasonable expectation that the individual's DNA would be present, regardless of the circumstance of the alleged crime. These include samples that originate directly from an individual's body (such as fingernails, hair, body orifice or body swabs), as well as clothing, accessories, and other personal effects documented as belonging to or removed from an individual.

2. The following formulas are adopted from The Evaluation of Forensic DNA Evidence, compiled by the Committee on DNA Forensic Science, National Research Council, and published through the national Academy Press (1996).

   a. Heterozygote frequencies will be calculated using the formula \( f(pq) = 2pq \). (NRC 1996 4.1b)

   b. Frequency calculations for homozygotes will be calculated using: \( f(pp) = p^2 + p(1-p)\theta \) with \( \theta = 0.01 \). (NRC 1996 4.4a) In cases of small, isolated populations (e.g., Native Americans), frequency calculations for that population will use 0.03 for \( \theta \).

   c. A five-event minimum allele frequency will be used for rare alleles (i.e. 5/2N.) For each individual allele, an observed allele count less than five is raised to five. This modified allele count is converted to a frequency and used for all subsequent genotype calculations.

   d. When a single allele is detected at a level (~200 RFU) where a paired allele may have been lost at a locus, the frequency of the stochastic allele in question is set at 2p. No assumption is made regarding the other allele. The 2p formula double-counts a homozygote, therefore another, more accurate representation of the genotype frequency is:

      i. \( f = 2 * p^*(1-p) \)

   e. In situations where more than one allele is at a level where a paired allele may have been lost, the stochastic alleles may be summed and multiplied by 2, with double counted homozygote and heterozygote combinations then subtracted. As an example, for stochastic alleles p and q:

      i. \( f = 2(p + q) - (p^2) - (q^2) - (2pq) \)

3. The laboratory has developed Excel worksheets to automatically calculate probabilities of inclusion using RMP (Random Match Probability), Modified RMP (selected genotypes), and CPI (Combined probability of Inclusion).
and Hispanic populations and will be calculated using the respective Heterozygote and Homozygote formulas described above. Frequency estimates will be reported to two significant figures. The source of the data used to calculate statistical frequencies will be cited and documented in the examiner's casework notes.

4. Biological relationships:

a. In cases where potential biological relationships exist between possible contributors and the evidence sample, the best course of action is to directly test those involved relatives who may have deposited the biological stain. In certain circumstances these reference samples may not be available. It is possible to estimate the conditional probability that a corresponding profile exists between relatives.

b. For non-inbred, unilineal relatives (generally non-sibling relationships) the following formulae estimate the chance probability of identical genotype:

   i. Homozygote: \( P = p_i^2 + 4p_i(1 - p_i)F \)  
      Heterozygote: \( P = 2p_ip_j + 2(p_i + p_j - 4p_ip_j)p_i \)  
      Where \( F \) is the kinship coefficient (parent and offspring = 1/4; half-siblings, uncle, nephew = 1/8; first cousins = 1/16.)

   ii. For siblings (with a bilineal relationship):

      i. Homozygote: \( P = (1 + 2p_i + p_i^2)/4 \)  
         Heterozygote: \( P = (1 + p_i + p_j + 2p_ip_j)/4 \)

5. Parentage Cases:

The laboratory uses Excel worksheets developed by DOJ to calculate Kinship Index.

a. The statistical significance of relationship (kinship) testing (including parentage) uses the Likelihood model where competing hypotheses are compared. Kinship testing is performed in certain situations. These include cases where an evidentiary stain/sample is compared to a relative, and for criminal paternity cases. In these cases, the likelihood ratio model is used to calculate the kinship (paternity, maternity, sibship, parentage) index.

b. Biological parent to child relationships may be estimated through the use of Paternity Index (PI) or Probability of Exclusion (PE) calculations. Paternity Index assesses the likelihood that a particular person is the biological parent of an individual compared to a random individual selected from the same population group. This relationship is generally reported as "it is X times more likely to observe the child's profile if the (suspect) is the biological parent of the child than observing the child's profile if the father is a randomly selected individual from the (race) population."

c. Probability of Exclusion estimates the probability of excluding a random individual as a biological parent from a selected population given the profiles of a child's and a known parent's profile. This relationship is generally reported as "the (suspect) is not excluded as the biological parent of the child. Approximately X% of randomly selected (race) individuals would be eliminated as the biological parent." The paternity formulas listed below require three genetic profiles for comparison:

   i. Known Parent
   ii. Child
   iii. Alleged Parent

d. Paternity Index: The likelihood of parentage is calculated according to the following ratio:

   Probability of genetic observations conditional on parentage

   \[ PI = \frac{\text{Probability of genetic observations conditional on parentage}}{\text{Probability of genetic observations conditional on non-parentage}} \]

   Probability of genetic observations conditional on non-parentage

f. The Parentage Index can be estimated for a DNA profile according to the product rule using the following equation:

   \[ PI = \prod_{i=1}^{n} P_{loci} \]
where PI of locus is estimated according to the genetic relationships listed in the PI and RMNE table below.

g. Probability of Exclusion:

i. The probability of exclusion is estimated for a DNA profile according to the product rule using the following expression:

\[
PE = 1 - \text{RMNE}_{\text{combined}}
\]

where \(\text{RMNE}_{\text{combined}}\) is the product of the individual RMNE estimates according to the genetic relationships listed in the PI and RMNE table below.

h. The following table lists the possible genotypic relationships among the three tested individuals. Given alleles A, B, C, and D with respective allele frequencies a, b, c, and d:

6. CODIS

a. Database Match Probability

A search against a database has more opportunities for comparing the evidence profile against multiple other profiles, therefore the chance of a coincidental match increases. The chance of a coincidental match increases even more when the profile has less discriminating potential, such as when it is a partial profile or mixture profile. The formula used to calculate the coincidental match is:

\[
N \times P
\]

N represents the number of individuals in the database at the time the CODIS match occurred. P represents the random match probability (RMP) calculated for the evidence profile.

An analyst will calculate and document the estimated coincidental match in their case notes. This calculation will typically be limited to case notes that support a CODIS confirmation examination. The coincidental match estimate will be reported in a laboratory report when the RMP is less than the size of the CODIS database at the time the match occurred. The purpose of reporting the coincidental match is to convey to the customer the significance of the match and its potential for a coincidental match.

When calculating and/or reporting the database coincidental match, an estimate should be reported for
each of the three major population groups (African American, Caucasian, and Hispanic). For example:

A coincidental match occurring with a person in the database is estimated to occur:

1 in XXXX databases of African Americans
1 in XXXX databases of Caucasians
1 in XXXX databases of Hispanics
I. Interpretation of STR Data

A. Introduction

1. The interpretation of results is a matter of professional judgment and expertise. Not every situation can be covered by a pre-set rule nor is it reasonable to expect that competent analysts will always be in full agreement in the interpretation of every case. However, it is the goal of the laboratory to develop criteria, based on validation studies, users’ manuals, literature references, and casework experience to provide a framework for objective interpretation of results that all analysts can follow. As technology progresses and the laboratory’s experience evolves with it, these interpretation guidelines will continue to evolve.

2. The purpose of these guidelines is to establish an outline to ensure interpretations are made as objectively and consistently as possible from analyst to analyst and to ensure reported conclusions are scientifically supported by the analytical data.

B. Relative Fluorescent Units:

Upon PCR amplification, STR fragments are created with primers that contain a fluorescent dye tag. The fragments are separated by base size when they pass through the capillary of the CE instrument. The fragments are detected when they pass the laser, which excites the dyes resulting in an emission of light. The emission spectra is captured by the CCD (Charged Coupled Device) camera and the signal is displayed as peaks. The resultant peak heights are a measurement of the amount of fluorescence detected. Therefore, there is a quantitative relationship between the amount of DNA amplified and the resultant peak height. The peaks are graphically displayed in six dyes by plotting the amount of signal detected which is displayed on the Y axis as relative fluorescent units (RFU) versus the electrophoresis time (scan number) which is displayed on the X axis. The graphical display is termed an electropherogram.

C. Thresholds used for Data Analysis and Interpretation

1. **Analytical Threshold (AT):** The minimum height requirement at and above which peaks can be reliably distinguished from background noise. Based on validation data, the minimum peak height threshold is 80 RFU for the blue, green, purple, and orange dyes and 110 for the yellow and red dyes. While peaks can be observed below the analytical threshold and may indicate the presence of a true allele, peaks below these levels will not be registered as alleles for reporting purposes.

2. **Stochastic Threshold:** The stochastic threshold (ST) is the peak height above which it is reasonable to assume that dropout of a sister allele of a heterozygote pair has not occurred. Based on validation data, the stochastic threshold is 600RFU. Peaks can readily be designated as alleles below 600RFU; however stochastic fluctuations are known to occur at this level. Depending on the interpretation being performed, peaks at/below the stochastic threshold may still be used for comparison and interpretation, but when peak heights are below 600RFU the potential for allelic drop-out of a paired peak should be considered. Note that when an allele is in a stutter position, the “stacking” of stutter with the peak can artificially inflate the peak height. Allele stacking must be considered when assessing whether a contributor's allele lies above or below the ST.

D. Levels of DNA Input

1. The optimal level of input DNA is 0.5 - 1.25 ng per amplification with a suggested target amount of 0.5 - 0.75ng for single source samples. Resolution of mixtures of two or more sources of DNA may require slightly higher input levels, such as 1.0 - 1.25 ng to adequately detect each donor. In cases of degraded DNA, excess template addition (>1.0 ng) can result in successful amplification.

2. During the validation, full single source profiles were detected consistently at 0.1 ng or above, and full single source profiles could be detected in some samples as low as 62pg.

3. **Optimal Level of DNA:** A target amount of 0.5ng for single source samples produced an average peak height of 3600 RFU during validation. Analyzed data values detected in the 600 to near 20000 RFU range provide...
adequate data for most interpretations.

4. **Trace/Stochastic Level DNA:** DNA detected below 600RFU is considered low level. Based on validation studies, it is reasonable to assume that at a given locus, allelic dropout of a sister allele has not occurred when DNA is detected above the stochastic threshold of 600RFU. Dropout should be taken into consideration when interpreting profiles with alleles below the stochastic threshold. Additional caution should be used when interpreting samples at this intensity level.

5. **Saturated Level DNA:** The CCD camera on the 3500 may become saturated at 27,500 RFU. Following peak detection, such peaks in the analyzed data are assigned an artificial height value which is not representative of the true amplitude. Peak height values for off-scale peaks should be used with caution in quantitative aspects of interpretation. Trace/stochastic level contributors should not be interpreted in mixture samples at loci with saturated data.

**E. Peak Height Ratios**

1. Peak height ratios are calculated by dividing the peak height (in RFUs) of the lower RFU allele by the peak height of the higher RFU allele, and then multiplying by 100 to express the PHR as a percentage.

2. Based on validation studies, the minimum expected PHR for single-source samples, where there is no indication of a mixture and 0.5ng of template DNA is amplified, is 60%. This ratio, however, may be lower with lower amounts of DNA. Peak-height-ratio imbalance may also result from degraded DNA or the presence of PCR inhibitors. The following peak height ratios should be used when assessing data at the following allele heights in RFUs.

<table>
<thead>
<tr>
<th>Allele height of taller peak (RFU)</th>
<th>PHR</th>
</tr>
</thead>
<tbody>
<tr>
<td>&gt;2500 RFU</td>
<td>60%</td>
</tr>
<tr>
<td>1400 - 2499 RFU</td>
<td>30%</td>
</tr>
<tr>
<td>600 - 1399 RFU</td>
<td>13%</td>
</tr>
</tbody>
</table>

**II. Steps of STR Data Interpretation** The interpretation of DNA data is considered a combination of qualitative and quantitative assessment. The primary goal of mixture interpretation shall be to determine the possible genotype combinations of the contributors. The determination of contributing genotypes will allow for inclusions or exclusions based upon those genotypes and not merely the presence or absence of alleles in a mixture. An analyst should note all analysis and interpretation within the case notes, including number of contributors, quality issues affecting the sample, assumptions used, and major/minor contributors deduced. Mathematical calculations must be shown to support the deduction of any major/minor contributors.

**A. Step 1: Characterize the quality of the amplification**

1. **Quality:** Evaluate those loci for which quality issues are suspected and where complete or partial drop out of alleles, and/or allele imbalances due to degradation, inhibition, or stochastic affects is possible.
   a. **Inhibition** is when a substance is present in the DNA sample that affects the amplification reaction. This may cause certain loci to amplify better than others regardless if they are high or low molecular weight loci.
   b. **Degradation** is when the DNA molecule has been broken into small pieces due to environmental insult or other factors. This results in a gradual loss of signal affecting the high molecular weight loci first and is often observed as a downward ski slope pattern. Degraded DNA can result in partial DNA profiles or no DNA results at all because the DNA fragments could not be amplified.
   c. **Differential Degradation** is where contributors to a DNA mixture possess different degrees of degradation. This is of particular importance with mixture interpretation where different contributions to a DNA mixture may have different levels of degradation; this could have a significant impact on interpreting mixture proportions across the profile depending on the severity of the disproportionate degradation.

2. **Quantity:** Evaluate whether the data in the sample is detected at low, or at optimal RFU levels. The overall quantity of DNA in the sample may be based on the overall allele height intensities or the sum of allele heights.
   a. **Peak height imbalance:** Peak height imbalances from known heterozygous paired alleles can randomly occur and were noted during validation to occur in samples across most loci and signal intensities. Peak height imbalances can result from stochastic effects in low amplified DNA, poor amplification, or more rarely, a tri-allelic pattern, or a primer site mutation. Peak height variation appears to be amplification mediated as imbalances were not reproducible between duplicate amplifications. Peak height ratios are one parameter considered in assessing mixtures, and more importantly, in assessing paired alleles in mixtures. Additional caution should be used in assigning major and minor contributor types in mixtures at lower intensity levels.
   b. When the DNA template copy number is low, stochastic PCR effects due to chance sampling may result in substantial imbalance between alleles. This alone is not a basis for excluding the data for interpretation or for concluding the imbalance is due to a mixture. While stochastic sampling is known to occur as input...
DNA amounts decrease, it is not observed in all amplifications of small DNA quantities. Single peaks <600 RFU (the lab’s stochastic threshold) will be evaluated for allelic drop out. If possible, the analyst can re-amplify or re-inject the sample to attempt to obtain reproducible amplification for comparison.

3. Objective signs of degradation and/or inhibition combined with DNA detected at low levels may impede the analyst’s ability to determine the number of contributors in a sample.
   a. When evaluating the overall quality and quantity of the sample, the analyst should consider whether the DNA data across all typeable loci is detected at a level where the number of contributors can be confidently assumed and whether there is data in a sufficient number of loci to clearly assess the number of contributors.
   b. When there is a possibility of allele drop-out and a fixed number of contributors to a mixture cannot be reasonably assumed for the component in question this leads to uncertainty about the possibility of entire genotypes being undetected in a mixture and the entire profile or a specific component (for example, minor component) may be considered uninterpretable.

B. Step 2: Determining whether the sample is single source or a mixture
   1. To assess if the sample is single source or a mixture, all alleles above the analytical threshold will be used. Peaks below the analytical threshold may be observed and considered in the interpretation regarding possible number of contributors.
   2. Single Source Profiles
      a. When the DNA data represented in a full profile contains no more than two alleles at each locus and each allele pair within a given locus is balanced within expectations, it is highly probable the DNA results are attributable to a single contributor. Exceptions to the two allele maximum per locus rule have been documented, those are persons with a triallele genotype and peak height imbalances from primer binding site variations.
   3. Partial Profiles
      a. Partial profiles can result from degraded or inhibited samples or samples originating from low quantity. A partial profile contains less genetic information for assessing the potential number of contributors in the sample; therefore, additional caution is needed when determining whether the observed DNA has originated from a single contributor. Partial profiles, while expressing less genetic information than a full profile, still can provide useful information for purposes of inclusion and exclusion.
      b. Single-source profiles with heterozygous alleles below stochastic threshold (ST): In single source samples, the primary concern with using alleles below ST is the possibility of allelic dropout. An apparent homozygous allele below ST may in fact be a heterozygote with dropout of the sister allele. If both sister alleles of a heterozygote are present below the ST, dropout is not a possibility and therefore the alleles may be considered a genotype. Because this relies on the assumption of a single-source sample, the assumption must be documented on the electropherogram and in the report.
   4. Mixture Profiles: (See flowchart at the end of this document)
      a. Generally a sample is considered to be a mixture of more than one individual if three or more alleles are present at more than one locus, and/or peak height ratios fall outside of expected ranges, suggesting allele sharing.

C. Step 3: Determine the number/minimum number of contributors in a mixture
   1. Evaluating the number of contributors in a mixture entails considering the number of alleles at all loci and the peak height ratio of those alleles in relation to each other.
   2. Number of Alleles: The minimum number of contributors can typically be estimated based on the locus with the greatest number of alleles, such as: Up to 4 alleles at a locus = at least 2-person mixture, 4 to 6 alleles at a locus = at least 3-person mixture, More than 6 alleles at a locus = at least 4-person mixture.
   3. When interpreting a mixture with multiple individuals, the possibility of additive allele sharing must be considered, where one peak may be from multiple copies of one allele from different donors. Allele sharing will be more common at less polymorphic loci and with relatives. The greater the amount of allele sharing the less likely the number of contributors can be recognized based on allele counting.
   4. Peak Height Ratios: Samples with peak height ratios falling outside the expected values for heterozygous samples can be an indication of a mixture. Stochastic effects and preferential amplification (smaller alleles being amplified better than larger alleles) may also account for the imbalances. When several peak height imbalances are observed with several alleles at a locus that cannot pair due to their peak height ratios, there is the potential for a greater number of contributors and greater potential for allele sharing to occur. For example, a mixture that presents as a two-person mixture based on the presence of 4 alleles, can actually be greater than two individuals
when three of the alleles cannot equally pair with the fourth allele. Additionally, each of the three alleles may
share a sister allele stacking in the fourth allele causing the peak height imbalance.

5. The number of contributors to a mixture may be assumed if information at all loci across the profile show no
indication of an additional contributor below threshold, peak heights are above stochastic threshold (at least for
the lower molecular weight loci), and there are at least five loci indicating that number of contributors (for
example 5 loci with 5 or 6 loci could indicate three-person mixture).

6. The three Y-STR loci contained within the Fusion 6C kit can be used for determining the minimum number of
males to a mixture. However, all males within a paternal bloodline will have the same Y-STR profiles and
therefore the actual number of males in a mixture will not be able to be determined, especially when relatives
may be contained within a mixture.

D. Step 4: Consider and factually describe known information from which reasonable inferences can be assumed
about the sample.

1. Intimate Samples: When the donor of the sample can be assumed to be present in the sample. An intimate
sample is any sample where there is a reasonable expectation that the individual's DNA would be present. These
include samples that originate directly from an individual's body (such as fingernails, hair, body orifice or body
swabs), as well as clothing belonging to or removed from an individual.

2. Once the assumed person is determined to be present in the mixture, the individual's contribution to the mixture
can be accounted for and used to deduce the profile(s) of the remaining contributor(s) in the mixture.

3. Proximal Evidence: An unknown DNA profile generated from a given item may be assumed to be potentially
observed elsewhere either on the same item of evidence or closely related evidence. For example, different swabs
collected from the same SAEK or swabs collected from different areas of the same firearm.

4. Familial Relationships: Given the case circumstances or the location of the collected evidence, there may be a
high potential for related individuals to be part of the mixture.

5. Different fractions of the same sample: When a sample is divided into different fractions, for example during a
differential digestion, the profiles generated from one fraction can be assumed to be present in the other fraction
and used to determine profiles in the other fraction. A statement such as “the sperm donor and the victim can
account for all the alleles detected” or similar can be reported.

E. Step 5: Mixture Interpretation: Determining the Average Mixture Proportion (Mx) and Mixture Deconvolution

1. Two-Person Mixtures

   a. Typically, mixtures showing a ratio of major to minor of 3:1 or greater (~75% major) can be clearly
distinguished, until approximately a 10:1 mixture, when determining a minor profile becomes more
difficult and dropout of the minor can start to occur. During validation, it was shown that mixtures of
DNA from two different sources could generally be recognized as mixtures even at a ratio of 100:1. A
clear major profile might not be able to be deduced from a mixture less than 3:1, but a set of genotypes
attributable to the major or minor might be able to be assigned to a given contributor.

   b. Loci Demonstrating Four Alleles: Calculate the average mixture proportion for the major contributor using
all loci demonstrating four alleles. The mixture proportion for four allele loci can be calculated using the
following formula:

   i. $M_{x_{major}} = \frac{\text{Sum of the major alleles}}{\text{Sum of the all alleles}}$

   c. Loci Demonstrating Three Alleles. Three allele loci can be used when the minor alleles can pair
exclusively with each other (i.e. major allele is homozygous) or the major allele is an assumed
contributor’s allele.

   i. $M_{x_{major}} = \frac{\text{The major allele}}{\text{Sum of all alleles}}$

   d. Similar to above, if a known contributor can be assumed to be present in the mixture, the average mixture
proportion and range can be calculated for the unknown contributor to the mixture instead of the major
contributor.

2. Three or Four Person Mixtures

   a. With the more extreme mixture proportions in three-person (~5:1:1 or greater) and four-person
(approximately ~8:1:1:1 or greater) mixtures (>70% major), a clear major contributor profile may be able
to be deduced. With less extreme mixture proportions, a clear major contributor profile may not be able to
be fully deduced. In some mixtures you may be able to fully deduce a major contributor profile at some
loci while you may only be able to deduce a "set of genotypes" at other loci.

   b. Mixture proportions may be applied to a donor or combination of donors in mixtures with more than two
contributors. It can be used to assess the proportion of major, minor, or intermediate donor(s) to the donor
pool. Mx should be calculated from all loci containing non-overlapping alleles and where all alleles are assumed to be detected for all donors.

c. **Three-person Mixtures**
   i. For 6 allele loci: \( Mx_{\text{major}} = \frac{\text{Two tallest alleles}}{\text{Sum of all alleles}} \)
   ii. For 5 allele loci where the major is a homozygote (can’t pair with any other allele): \( Mx_{\text{major}} = \frac{\text{Tallest allele}}{\text{Sum of all alleles}} \)

d. **Four-person Mixtures**
   i. For 8 allele loci: \( Mx_{\text{major}} = \frac{\text{Two tallest alleles}}{\text{Sum of all alleles}} \)
   ii. For 7 allele loci where the major is a homozygote (can’t pair with any other allele): \( Mx_{\text{major}} = \frac{\text{Tallest allele}}{\text{Sum of all alleles}} \)

e. 5 and 7 allele loci where the major is heterozygous and the remaining alleles are at a low level may be used when calculating Mx if the contribution of the trace component is deemed to be insignificant. This can be done by accounting for the possibility that the sister allele of the tallest trace allele may be present in the two tallest alleles and subtracting that from the sum of the two tallest peaks.

3. An average mixture proportion can be calculated as well as a range of acceptable mixture proportions based on the loci where all contributors’ alleles are represented in the locus. Once the average Mx is calculated a range of acceptable Mx can be calculated using the average mixture proportion ± .25. This will give a range of acceptable mixture proportions, for deducing a set of genotypes. Calculate Mx for the remaining loci and determine if they fit in the acceptable Mx range.

4. The quality of DNA results and how they affect the interpretation of proportions overall needs to be considered. Evaluate whether the proportions remain constant across the loci (even under degrading conditions) or if there is evidence of differential degradation between the contributors. Separate mixture proportions may need to be calculated from low molecular weight and high molecular weight loci. A range +/- 0.30 may also be used for samples that may show evidence of inhibition or degradation.

5. When assessing peak height proportions in a deconvolution, the peak height ratios for potential heterozygous pairs are typically performed using an assumed 100% peak height balance but can also be performed using the highest peak imbalance seen for an allele of its height.

6. **Issues with minor contributors involving stutter**
   a. Generally, when the height of a peak in the stutter position exceeds the laboratory’s stutter expectation for a given locus, that peak is consistent with being of allelic origin and should be designated as an allele.
   b. For a minor allele in a stutter position, stutter from a major allele may cause an artificial imbalance in the PHR calculation results of minor genotypes. This should be considered in deconvolution when deriving potential genotypes from applied minimum PHR expectations and the calculated Mx range. This can be done by using the stutter threshold to determine how much of the peak could be from stutter and subtracting that from the height of the peak.
   c. A minor allele may also be potentially located in the same location as a stutter peak and may not be detected as a true allele if the total RFU does not surpass the stutter percentage. Stutter peaks should be considered as possible allelic peaks when the stutter peaks are at heights consistent with or greater than the minor contributor peaks.

F. **Step 6: Characterize the Mixture**

1. **Mixtures displaying distinguishable major and/or minor contributors at all loci**:
   a. A distinguishable mixture contains a distinct contrast in signal intensities (e.g., peak heights) between the different contributors’ alleles which allows for the interpretation of the major contributor and possibly the minor contributor. Discernment of the STR typing results for the major or minor contributor to a mixture may effectively constitute deduced single-source profiles, or in other instances may be limited to single genotypes at only some loci with the remaining loci yielding multiple potential genotypes for the major or minor contributor.
   b. A distinguishable mixture would be one where at loci with non-overlapping alleles the two tallest peaks have PHR >60% (or 30% for peaks 2499 - 1400 RFU) with one another and the PHR between the major and minor alleles is <60%. (or 30% for peaks 2499 - 1400 RFU).
   c. The average \( Mx_{\text{major}} \) for 3 and 4 person mixtures should be greater or equal to 0.65 and 0.6, respectively.
   d. **Minor contributors**
After deconvolution, the DNA typing results attributed to a single minor contributor should also meet PHR expectations. The PHR expectations of a minor contributor may be reduced due to stochastic peak height variation and the additive effects of peak sharing (e.g., minor peak and stutter peaks). Determination of a single genotype for a minor contributor may be possible at only some loci because multiple possible genotype combinations, potential allelic dropout, and/or masking of the minor contributor’s alleles by those of the major contributor or by stutter from the major contributor’s alleles preclude such determination at other loci. Probabilistic genotyping may be helpful in these situations.

2. Mixtures with a major component of two contributors and one or more minor contributors
   a. A set of possible genotypes can be assigned to a mixture profile when the number of contributors in the mixture or in the interpreted component of the mixture (i.e. major component) can be defined and the quality of the DNA results supports that all of the DNA from the defined number of contributors can be accounted for in the mixture (i.e complete drop of any one contributor has not occurred). A complete mixture profile or a partial mixture profile may result from the interpretation and is dependent on the complexity and quality of the DNA results.
   b. For a mixture to be classified as having a major component of two contributors the following must be met at the loci containing the most alleles:
      i. The Average Mx for the major component must be at least 0.75
      ii. None of the 4 tallest alleles should be able to pair with the shorter alleles.
      iii. If there are 3 tall peaks, the shortest of the three taller peaks cannot be fully explained by being shared with the shorter peaks.
   c. The interpretation of the “major mixture” may be performed regardless of the interpretation of the “minor portion” of the mixture (i.e., the “minor portion” may be uninterpretable).

3. Mixture with indistinguishable contributors:
   a. In some mixed samples, major or minor contributors may not be able to be deduced due to similar contributions of DNA. If there is no significant difference, a major/minor proportion cannot be categorized quantitatively. This results in an indistinguishable mixture at some or all loci. However, an assumption as to the number of contributors can be used to limit genotype possibilities in some instances (e.g., a four allele locus in a two-person mixture is not reasonably expected to have any homozygous genotypes contributing).
   b. If an assumption as to the number of contributors can be made and it can be demonstrated that all contributors are present at a locus, all possible genotype combinations for any contributor can be determined at that locus and used for inclusions/exclusions. If an assumption as to the number of contributors cannot be made, due to quality issues, such as stochastic level alleles and the potential for missing genetic information it may prohibit interpretation of the mixture.
   c. A mixture is considered to be indistinguishable when at the loci containing the most alleles the criteria for determining a single major contributor or a major component of two contributors mentioned above cannot be met.

G. Step 7: Comparison with Known Samples and Conclusions:
   1. The following conclusions are used to address comparisons between casework questioned samples and reference samples:
      2. Exclusion (Elimination): A person will be reported as being "excluded" when the sample has one or more non-matching alleles when compared to the reference source. The result should be reported as ".... is excluded as the source of the DNA." or similar wording.
      3. Inclusion (match): A person will be reported as "included" when the sample matches across all interpreted loci when compared to the reference source. The result should be reported as ".... likely is the source of the DNA profile" or ".... is included as a possible source of the DNA" or similar wording. Inclusions will be qualified with a statistical analysis of the estimated frequency of occurrence of the questioned stain profile (see statistical analysis below) or a qualitative statement.
      4. Uninterpretable/Inconclusive: A conclusion of "uninterpretable" or "inconclusive" is reported in situations when much of the genetic information is at stochastic levels, or when the mixture is too complex, the number of contributors cannot be assumed, and no major/minor components can be distinguished. A determination of inconclusive may apply to one component of a mixture (i.e., minor contributor results in a mixture with an interpretable major component) or to the overall results (i.e., low-level possible mixture with peaks below the analytical threshold). No conclusion (i.e., inclusion/exclusion) can be drawn from the comparison of a reference
sample to inconclusive data. An example of such an inconclusive result is "The DNA result/mixture is not suitable for comparison due to the low level and uncertainty in the number of contributors".

5. **No results:** A conclusion of "no result" is reported when no amplified DNA has been detected above the analytical threshold at all loci. The result should be reported as "No DNA results were obtained" or similar.

**H. Step 8: Statistical Analysis**

1. Statistical interpretations provide an objective means to assess the strength or significance of an inclusion (match). All inclusions of a probative nature will have a statistical interpretation provided. Statistical calculations are not required to support the inclusion of an individual on his or her own intimate sample.

2. **Random Match Probability (RMP)**
   a. The RMP calculation is defined as the probability of randomly selecting an unrelated individual from a population who could be a potential source of the evidentiary DNA profile. Typically, a RMP statistic is applied to a single source sample, or a deduced single source major or minor contributor to a mixture.
   b. The following formulas are adopted from *The Evaluation of Forensic DNA Evidence*, compiled by the Committee on DNA Forensic Science, National Research Council, and published through the national Academy Press (1996).
   c. Heterozygote frequencies will be calculated using the formula \( f(pq) = 2pq \). (NRC 1996 4.1b)
   d. Frequency calculations for homozygotes will be calculated using: \( f(pp) = p^2 + p(1-p)\theta \) with \( \theta = 0.01 \). (NRC 1996 4.4a) In cases of small, isolated populations (e.g., Native Americans), frequency calculations for that population will use 0.03 for \( \theta \).
   e. A five-event minimum allele frequency will be used for rare alleles (i.e. 5/2N.) For each individual allele, an observed allele count less than five is raised to five. This modified allele count is converted to a frequency and used for all subsequent genotype calculations.
   f. When a single allele is detected at a level (<600 RFU) where a paired allele may have been lost at a locus, the frequency of the stochastic allele in question is set at 2p. No assumption is made regarding the other allele's type (all alleles are possible). The 2p formula double-counts a homozygote, therefore another, more accurate representation of the genotype frequency is:
      i. \( f = 2p^*(1-p) \)
   g. In situations where more than one allele is at a level where a paired allele may have been lost, the stochastic alleles may be summed and multiplied by 2, with double counted homozygote and heterozygote combinations then subtracted. As an example, for stochastic alleles p and q:
      i. \( f = 2(p + q) - (p^2) - (q^2) - (2pq) \)

3. **Modified Random Match Probability (mRMP)**
   a. The modified RMP follows the same statistical formulae and process described for the RMP, but first sums the individual frequencies for the possible "set of genotypes" at each locus prior to applying the product rule. This is used when a clear major or minor is unable to be determined and a set of genotypes for that contributor(s) is deduced.
   b. Due to the application of theta (\( \theta \)) for homozygotes, avoidance of double counting of genotype frequencies should be made; however, a calculated mRMP may occasionally exceed 1.0 at a locus. In these instances, the analyst will report the value as 1.0 at that locus.

4. **Combined Probability of Inclusion (CPI)**
   a. The CPI calculation is defined as the probability that a randomly selected individual from a population of unrelated individuals could be a potential contributor to a given DNA mixture. CPI does not rely upon distinguishing individual donors into major or minor contributors, nor does it necessarily require an assumption of the number of contributors. The CPI module calculates the frequency of "every" possible genotype combination at a given locus based on the set of alleles detected at that locus. As a result, the frequency of the set of genotypes at each locus are summed and each locus is multiplied. CPI assumes each of the donors are fully represented in the set of alleles detected, therefore CPI requires good amplification of each of the contributors in the mixture (i.e. no drop out). In most cases, CPI can only be used for well amplified mixture samples, typically consisting of no more than 2 to 3 donors.
   b. The following is the CPI formula: \( f = (p_1 + p_2 + \ldots + p_k)^2 \) where \( p_1 + p_2 + \ldots + p_k \) are the frequencies of the alleles detected at the locus, and \( k \) is the number of alleles. The frequencies determined for each locus may then be incorporated into the product rule.

I. **Reporting Statistics**
1. The laboratory has developed an Excel workbook “STRstat Fusion” to automatically calculate probabilities of inclusion using RMP (Random Match Probability), Modified RMP (selected genotypes), and CPI (Combined probability of Inclusion).

2. Population frequency estimates will generally be given for African American, Caucasian, Asian, and Hispanic populations and will be calculated using the respective Heterozygote and Homozygote formulas described above.

3. Frequency estimates will be reported to two significant figures.

4. Source bibliographic information for the database used in calculating statistical frequencies will be documented in the casework notes.

5. A profile or component from any intimate sample which is solely attributable to an “owner” is not used for statistical analysis, but is addressed in the report with a qualitative statement.

6. The Y-STR loci will not be used for statistical purposes.

J. Kinship Cases:

1. The laboratory uses the KIn CALc Excel workbook developed by Cal DOJ to calculate Kinship Index.

2. The statistical significance of relationship (kinship) testing (including parentage) uses the Likelihood model, where competing hypotheses are compared. Kinship testing is performed in certain situations. These include cases where an evidentiary stain/sample is compared to a relative, and for criminal paternity cases. In these cases, the likelihood ratio model is used to calculate the kinship (paternity, maternity, sibship, parentage) index.

3. Biological parent to child relationships may be estimated through the use of Paternity Index (PI) calculation. Paternity Index assesses the likelihood that a particular person is the biological parent of an individual compared to a random individual selected from the same population group. This relationship is generally reported as "it is X times more likely to observe the child's profile if the (suspect) is the biological parent of the child than observing the child's profile if the father is a randomly selected individual from the (race) population."

4. The paternity formulas listed below require three genetic profiles for comparison:
   a. Known Parent
   b. Child
   c. Alleged Parent

5. Paternity Index: The likelihood of parentage is calculated according to the following ratio:

\[
P_I = \frac{\text{Probability of genetic observations conditional on parentage}}{\text{Probability of genetic observations conditional on non-parentage}}
\]

6. The Parentage Index can be estimated for a DNA profile according to the product rule using the following equation:

\[
P_I = \prod_{\text{loci}} P_I^{\text{locus}}
\]

   a. Where PI of locus is estimated according to the genetic relationships listed in the PI table below.

7. The following table lists the possible genotypic relationships among the three tested individuals.

8. Given alleles A, B, C, and D with respective allele frequencies a, b, c, and d:
K. CODIS

1. Database Match Probability (NP)

   a. A search against a database has more opportunities for comparing the evidence profile against multiple other profiles, therefore the chance of a database match increases. The chance of a database match increases even more when the profile has less discriminating genetic data, such as when it is a partial profile or a mixture profile. The formula used to calculate how often a DNA profile matching the forensic unknown sample profile would be found in a database of size N is:

   i. \( N \times P \)

   ii. \( N \) represents the number of individuals in the database at the time the CODIS match occurred.

   iii. \( P \) represents the random match probability (RMP) calculated for the evidence profile.

   b. An analyst may calculate and document the estimated database match probability in their case notes. This calculation typically will be limited to case notes that support a CODIS confirmation examination. The coincidental match estimate will be reported in a laboratory report when the RMP is less than the size of the CODIS database at the time the match occurred. The purpose of reporting the database match probability is to convey to the customer the significance of the match and its potential for a coincidental match. This is a very conservative approach to the National Research Council’s recommendation since each major population group is being multiplied by the entire number of individuals in the database.

   c. When calculating and/or reporting the database match probability, an estimate should be reported for each of the four major population groups (African American, Caucasian, Asian, and Hispanic). For example:

   i. The expected number of DNA profiles in the database that would match the evidence profile is estimated to be:

      1. 1 in XXXX databases comprised of African Americans
      2. 1 in XXXX databases comprised of Caucasians
      3. 1 in XXXX databases comprised of Hispanics
      4. 1 in XXXX databases comprised of Asians

L. Definitions:

1. Allelic dropout: failure to detect an allele within a sample or failure to amplify an allele during PCR.
2. Composite profile: a DNA profile generated by combining typing results from different loci obtained from multiple injections of the same amplified sample and/or multiple amplifications of the same DNA extract.
3. Deconvolution: separation of contributors to a mixed DNA profile based on quantitative peak height information and any underlying assumptions.
4. Deduced: inference of an unknown contributor’s DNA profile after taking into consideration the contribution of a known/assumed contributor’s DNA profile based on quantitative peak height information.
5. **Distinguishable Mixture**: a DNA mixture in which relative peak height ratios allow deconvolution of the profiles of major/minor contributor(s).

6. **Indistinguishable Mixture**: a DNA mixture in which relative peak height ratios are insufficient to attribute alleles to individual contributor(s).

7. **Masked allele**: an allele of the minor contributor that may not be readily distinguishable from the alleles of the major contributor or an artifact.

8. **Mixture ratio**: the relative ratio of the DNA contributions of multiple individuals to a mixed DNA typing result, as determined by the use of quantitative peak height information; may also be expressed as a percentage.

9. **Partial profile**: a DNA profile for which typing results are not obtained at all tested loci due, for example, to DNA degradation, inhibition of amplification and/or low quantity template.

10. **Stochastic effects**: the observation of intra-locus peak imbalance and/or allele drop-out resulting from random, disproportionate amplification of alleles in degraded or low-quantity template samples.

11. **Contributor**: a unique DNA profile provided to a sample from one individual. This DNA profile is presumed to adhere to the principle of cellular organization (paired autosomal alleles).
   a. Major contributor(s): an individual(s) who can account for the predominance of the DNA contributed to a sample.
   b. Minor contributor(s): an individual(s) who can account for the lesser portion of the DNA in a mixed profile.

12. **Component**: an assessed combination of genetic traits observed in a biological sample. A component may be comprised of one or more contributors. Assessment of components takes into account the expectation of cellular organization (paired autosomal alleles), knowledge about the specific sample in question (e.g. expected contribution from an intimate contributor), and variation resulting from environmental, amplification, and mixture effects.

13. Components are generally assessed based on intensity and may be referred to as:
   a. Major/Predominant
   b. Intermediate/Minor
   c. Minor/Trace

### IV.
DNA Mixture Interpretation Flowchart
I. Quality Control

A. The following quality control measures are taken to minimize the risk of contamination:

   1. Wipe down the Nimbus workstation and work area with a diluted bleach solution before starting a run. A non-bleach disinfectant such as Microside SQ may be used for stainless steel surfaces. For either disinfectant, follow with a wipe-down with water to remove any remaining residue and then ethanol to help with drying.

   2. Perform weekly maintenance when required by the Nimbus system.

      a. The Hamilton Run Control software will not load if the weekly maintenance has not been performed.

      b. To perform the weekly maintenance, double click the Nimbus Maintenance icon on the Desktop. Select Weekly as the maintenance type and click Run Maintenance to continue. Perform and check off each item when prompted. Remove tip eject plate for tightness and cLLD checks. Click Close when weekly maintenance is complete and replace the tip eject plate prior to any Nimbus setup runs.

II. Barcoding Procedure

A. Double click on the "Barcodes File.csv" file icon on the designated barcoding computer Desktop.

B. Cell A1 is labeled "Barcode"; add lab and item numbers of samples (or standards, controls, names of quantitation/amplification/normalization plates, reagents, etc.) in the subsequent rows.

   NOTE: Limit the number of characters and special characters when possible. Excessive characters may make the barcode too long and unscannable for the Nimbus.

   NOTE: All barcodes are case sensitive. Ensure barcodes match the case of the samples in worklists to avoid downstream issues.

C. Click the Save icon, then Yes to keep the file as CSV format, and close the document without saving (Don’t Save) when prompted again.

D. Double click on the Bartender software "CCC Barcode.btw" icon on the Desktop.

E. Once the software opens, click the Print button on the toolbar.

F. In the following Print dialogue window, click the Select Records button.

G. In the Select Records dialogue window, enable checkboxes for the samples that are to have barcodes printed. Click OK to return to the Print window.

H. Click Print on the Print window.

I. The labels then print out from the Zebra LP 2824 Plus adjacent to the computer. Trim the label and affix using the following guidelines:

   1. For 2.0mL dolphin tubes, place barcodes vertically just below the front tube lip.

   2. For skirted amplification plates, place barcodes horizontally on the right side, centered, near the top of the plate.

   3. For deep well normalization plates, place barcodes horizontally on the right side, centered and near the top.

   NOTE: Plates do not necessarily need a barcode. As long as identifying information is placed in the designated location, whether barcoded or handwritten, it may still be scanned or typed into the input fields of the Nimbus method.

J. Close out of the Print dialogue window, then Exit out of the Bartender software. Click No when asked to save changes.

III. Quantification Setup

A. Scope/Principle/Purpose: This procedure describes the automated setup of the Promega PowerQuant DNA quantification kit by the Hamilton Nimbus liquid handling platform. Standards, controls, and extracted samples are prepared in 2.0mL microcentrifuge tubes with unique barcodes. Source positions, destination positions, and barcodes as well as kit information are contained in an Excel-based file prepared by the user and read by the Hamilton Run Control software. This setup method provides prompts to load samples, reagents, and plates on the instrument deck and includes an option to prepare the master mix. The instrument dispenses the master mix to the reaction plate, followed by the transfer of samples, standards, and controls from barcoded tubes into designated wells as dictated by the user-prepared worklist. The quantification plate is then sealed, centrifuged, and ready for qPCR analysis.
B. Reagents:

1. Promega PowerQuant System

C. Equipment and Supplies:

1. Hamilton Microlab Nimbus Workstation
2. 2.0mL Screw Cap Tube with Cap
3. 96-Well Optical Reaction Plate
4. Optical Adhesive Film
5. Plate Centrifuge

D. Procedure:

1. Thaw the appropriate kit reagents if necessary.
2. Ensure all samples, standards, controls, and reagents are vortexed and barcoded or labeled.
3. Create a worklist using the DNA sample setup workbook or create a worklist manually. Worklists for quantitation plate setup must be in CSV (comma delimited, *.csv) file format and in the Desktop\Nimbus Worklist\Quant folder for the method to run.
   a. To create a worklist from the DNA workbook, select the "Nimbus Quant WL" tab and Save As with the following name and file extension: WL.csv. Proceed to follow the remaining instructions to clear the contents of empty cells in the “Instructions” tab and move it to the above specified folder.
   b. To create a worklist manually on the pre-amp Nimbus instrument computer:
      i. Open the “WL.csv” file located in the Desktop\Nimbus Worklists\Quant folder. Enter information for each sample per row as follows:

<table>
<thead>
<tr>
<th>A</th>
<th>B</th>
<th>C</th>
<th>D</th>
<th>E</th>
<th>F</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enter &quot;Tube&quot; for the type of container the sample is in</td>
<td>Enter Barcode of sample tube (case sensitive)</td>
<td>Enter &quot;T&quot; to indicate sample is in a tube</td>
<td>Enter &quot;Amp1&quot; for the destination plate position on instrument deck</td>
<td>Enter the destination well position in the rxn plate (e.g., A1, B1,...)</td>
<td>Enter &quot;PQ&quot; to specify quant kit</td>
</tr>
</tbody>
</table>

   ii. Click the Save icon, then Yes to keep the file as CSV format, and close the document without saving (Don’t Save) when prompted again.
4. This Nimbus setup method also requires a reagent worklist (RWL.csv) in the Desktop\Nimbus Worklists\Quant folder in order to run. This file specifies the reagents needed to prepare the master mix. Do not edit or move this file regardless of the manner of master mix preparation (see Appendix Table A).
5. Power on the Nimbus Workstation and open the Hamilton Run Control software from the Desktop.
6. Select File, then Open, and navigate to the C:\Program Files (x86)\HamiltonCompany\Methods\Nimbus folder and select AmpNimbus.med.
7. After the software has connected to the Nimbus, click the green play icon in the toolbar to start. Follow the on-screen prompts to complete the run.
   a. Select the type of kit amplification plate setup: Quantification, then click OK.
   b. Tip check: Three Edit Tip Count windows appear one after another with the available 1000µL, 300µL, and 50µL tips highlighted, respectively. Verify that the tip check is accurate and click OK. If the check is not accurate on any screen, select or deselect those positions to reflect the actual placement of pipette tips on deck. Click OK to proceed.
      IMPORTANT: Make sure there are enough tips to completely process the plate and that there is sufficient space for tip waste. If tips are exhausted during the run, this will cause a critical error and the entire run must be redone (see Appendix Table B).
   c. Scan or type in the barcode of the reaction plate (using the quant log numbering convention: B/CYY-NNN, where Y is the year and N is the run number) and place it in the Amp1 position of the instrument deck. See Appendix Figure 1.
   d. Place barcoded samples/standards/controls in any of the Shift-N-Scan racks and load racks onto instrument deck, either capped or uncapped at this time. Ensure all barcodes are visible through the opening in the tube holders.
   e. The Nimbus then scans the barcoded samples in the Shift-N-Scan racks and displays all tubes that were successfully scanned in the Barcode Handler window. Samples from the worklist that were not scanned are listed in the “Barcodes Not Found” column. These missing sample barcodes can be scanned in manually by clicking on its corresponding location in the Barcode Handler screen and scanning the barcode with the handheld scanner. Alternatively, the sample name/barcode may be typed into the corresponding cell. When all worklist samples are represented, click OK to proceed.
   f. The quant plate setup method provides an option for preparing the master mix.
i. Select No to prepare the master mix manually. Place the prepared and vortexed 2mL screw cap tube of master mix at position 1 of the reagent block (see Appendix Figure 1). Click OK to continue.

ii. Select Yes to have the Nimbus prepare the master mix. Follow the onscreen prompt’s to scan and place the following tubes uncapped at the specified positions on the reagent block (see Appendix Figure 2):

- an empty 2mL screw cap tube for master mix at position 1
- reaction mix at position 4; scan or type RxnMix
- amplification grade water at position 3; scan or type: AmpWater
- primer mix at position 2; scan or type: PrmrMix

iii. After preparing the master mix, the method prompts the user to remove and vortex/spin down the master mix. Visually check that it is of sufficient volume and appropriate color. Return the master mix uncapped to position 1 on the reagent block and click OK to continue.

g. The robot then proceeds to dispense the master mix. After every two columns of dispensing, the method prompts the user to spin down the master mix tube and return it to the reagent block.

h. When master mix aliquoting is finished, remove the quant plate from the instrument deck and visually inspect the volumes in each well. If any well is not uniform, rectify the issue by manually removing all liquid from that well and pipetting the correct amount of master mix (18µL for quantitation setup) back into that well. Replace the plate when ready and click OK.

i. If sample tubes are not already uncapped, do so now.

j. The robot then transfers extracts from sample tubes to the quant plate.

k. When finished, a completed run screen appears. Press OK to finish the method.

8. Remove the quant plate from the instrument deck and close the Nimbus door. Return when ready to clean up.

9. Seal the quantification plate with optical adhesive film in a PCR prep hood and proceed to spin down in a plate centrifuge to remove any bubbles. The plate is now ready to be loaded for qPCR analysis.

10. Return to the Nimbus work area, cap and store sample and reagent tubes, clean the instrument deck, exit out of the Hamilton Run Control software, and power off the Nimbus workstation.

11. Return to the Desktop\Nimbus Worklists\Quant folder, move a copy of “WL.csv” file into the Archive subfolder, and rename that copy to include the date and user initials.

IV. Normalization

A. Scope/Principle/Purpose: This procedure describes the automated normalization of samples by the Hamilton Nimbus liquid handling platform in 96-well deep well plates. Source positions, destination positions, extract volumes, and diluent volumes are contained in an Excel-based file prepared by the user and read by the Hamilton Run Control software. The Normalization method provides prompts to load samples and diluent on the instrument deck. The instrument transfers the required volumes of diluents and sample extracts into the designated wells of a deep well normalization plate.

B. Reagents:

1. TE\(^{-4}\) Buffer

C. Equipment and Supplies:

1. Hamilton Microlab Nimbus Workstation
2. 96-Well Deep Well Plate
3. Sealing Mat for Deep Well Plate
4. Centrifuge
5. 50mL Reagent Trough

D. Procedure

1. Ensure enough diluent (TE\(^{-4}\) Buffer) is present in the 50mL reagent trough and leave it uncovered for the duration of this method.

2. Ensure all samples have the correct barcode and are vortexed and centrifuged. Written or barcoded identifying information for deep well plates have the following naming convention: NormMMDYYXX.

3. Create a normalization worklist using the DNA sample setup workbook or create a sample worklist manually. Worklists for quantitation plate setup must be in CSV (comma delimited, *.csv) file format and in the Desktop\Nimbus Worklist\Dilutions folder for the method to run.

   a. Follow the workbook’s “Amp Prep” instructions when selecting samples for amplification and the corresponding options for tube dilution or manual preparation if necessary. Take note of any colored cells that may appear.
i. Samples requiring a dilution default to normalization prep, unless tube dilution is selected. Use the **tube dilution** option when the dilution required is >1:500, which is the highest dilution the Nimbus can prepare. Barcode and retain tube dilutions for amplification plate preparation by the Nimbus.

ii. Use the **manual preparation** option for dilutions involving 10µL+ of extract and samples requiring concentration. Retain these manually prepared samples to add to the amplification plate after the Nimbus has completed its setup of the amp plate.

iii. When all normalization samples are sorted out, heed the instructions to import and save the “**Norm WL**” sheet as **WL.csv**.

iv. As instructed, edit the worklist for normalization setup and move it to the *Desktop\Nimbus Worklists\Dilutions* folder on the pre-amp Nimbus instrument computer.

b. To create a worklist manually on the pre-amp Nimbus computer:

i. Open the “**WL.csv**” file located in the *Desktop\Nimbus Worklists\Dilutions* folder. Enter information for each sample per row as follows:

<p>| | | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td>C</td>
<td>D</td>
<td>E</td>
<td>F</td>
</tr>
<tr>
<td>Enter &quot;1&quot; to indicate Shift-N-Scan racks as the sample source location</td>
<td>Enter tube Barcode of sample (case sensitive)</td>
<td>Enter &quot;T&quot; to indicate sample extract is in a tube</td>
<td>Enter “Norm1” for the destination plate position on instrument deck</td>
<td>Enter the destination deep well plate position (e.g., A1, B1,...)</td>
<td>Volume of DNA extract sample (minimum volume the Nimbus can pipet is 2µL)</td>
</tr>
<tr>
<td>Volume of diluent (maximum 1000µL)</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

ii. Click the **Save** icon, then **Yes** to keep the file in .CSV format and close the document without saving (**Don’t Save**) when prompted again.

4. Power on the Nimbus Workstation and open the *Hamilton Run Control* software from the *Desktop*.

5. Select **File**, then **Open**, and navigate to the *C:\Program Files (x86) \HamiltonCompany\Methods\Nimbus* folder and select **NormNimbus.med**.

6. After the software has connected to the Nimbus, click the **green play** icon in the toolbar to start. Follow the on-screen prompts to complete the run.

   a. Tip check: Three **Edit Tip Count** windows appear one after another with the available 1000µL, 300µL, and 50µL tips highlighted, respectively. Verify that the tip check is accurate and click **OK**. If the check is not accurate on any screen, select or deselect those positions to reflect the actual placement of pipette tips on deck. Click **OK** to proceed.

   IMPORTANT: Make sure there are enough tips to completely process the plate and that there is sufficient space for tip waste. If tips are exhausted during the run, this will cause a critical error and the entire run must be redone (see Appendix Table B).

   b. Place barcoded sample tubes in any of the Shift-N-Scan racks and load racks onto instrument deck, either capped or uncapped at this time. Ensure all barcodes are visible through the vertical opening in the tube holders.

   c. The Nimbus then scans the barcoded samples in the Shift-N-Scan racks and displays all tubes that were successfully scanned in the **Barcode Handler** window. Samples from the worklist that were not scanned are listed in the “**Barcodes Not Found**” column. These missing sample barcodes can be scanned in manually by clicking on their corresponding location in the **Barcode Handler** screen and scanning the barcode with the handheld scanner. Alternatively, the sample name/barcode may be typed into the corresponding cell. When all worklist samples are represented, click **OK** to proceed.

   d. Place the 96-well deep well plate in the “**Norm1**” position on the instrument deck. See Appendix Figure 1.

   e. The robot then transfers diluents to the deep well plate.

   f. If sample tubes are not already uncapped, do so now.

   g. The robot then transfers sample extracts to the deep well plate.

   h. When finished, a completed run screen appears. Press **OK** to finish the method.

7. Remove the deep well plate from the instrument deck and cover it firmly with a sealing mat. Vortex the plate briefly to mix the samples, then centrifuge the plate. The normalized samples are now ready to proceed to amplification plate setup.

   IMPORTANT: In order for the downstream Nimbus amp plate setup method to recognize this normalization plate, the corresponding normalization “**WL.csv**” file must remain where it is in the *Desktop\Nimbus Worklists\Dilutions* folder.

8. Return to the Nimbus work area to cap the samples and cover the reagent trough.

9. Clean the instrument deck, exit out of the *Hamilton Run Control* software, and power off the Nimbus workstation.

10. Return to the *Desktop\Nimbus Worklists\Dilutions* folder, move a copy of the “**WL.csv**” file into the **Archive** subfolder, and rename that copy to include the date and user initials.
V. Amplification Setup

A. Scope/Principle/Purpose: This procedure describes the automated setup of the Promega PowerPlex Fusion 6C amplification kit by the Hamilton Nimbus liquid handling platform. Samples are prepared in 2.0mL microcentrifuge tubes and/or a 96-well deep well plate with unique barcodes. Source positions, destination positions, and barcodes as well as kit information are contained in an Excel-based file prepared by the user and read by the Hamilton Run Control software. This setup method provides prompts to load samples, reagents, and plates on the instrument deck and includes an option to prepare the master mix. The instrument dispenses the master mix to the amplification plate, followed by the transfer of samples, standards, controls, and dilutions from barcoded tubes or a normalization plate into designated wells as dictated by the user-prepared worklist. Any manually prepared samples may be added to the plate at this point before the amplification plate is finally sealed and ready for thermal cycling.

B. Reagents:

1. Promega PowerPlex Fusion 6C System

C. Equipment and Supplies:

1. Hamilton Microlab Nimbus Workstation
2. 2.0mL Screw Cap Tube
3. 96-Well Reaction Plate
4. MicroAmp Clear Adhesive Film, Strip Caps, or Strip Cap Mat
5. Plate Centrifuge

D. Procedure

1. Thaw the appropriate kit reagents if necessary.
2. Ensure all samples, standards, controls, and reagents are vortexed and barcoded or labeled.
3. Create a worklist using the DNA sample setup workbook or create a worklist manually. Worklists for amplification plate setup must be in CSV (comma delimited, *.csv) file format and in the Desktop/Nimbus Worklist/Amp folder for the method to run.
   a. To create a worklist from the DNA workbook, select the ”Nimbus Amp WL” tab and Save As with the following name and file extension: WL.csv. Proceed to follow the remaining instructions to clear the contents of empty cells in the “Instructions” tab and move it to the above specified folder.
   b. To create a worklist manually on the pre-amp Nimbus computer:
      i. Open the “WL.csv” file located in Desktop/Nimbus Worklists/Amp folder. Enter information for each sample per row as follows:

<p>| | | | | | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>A</td>
<td>B</td>
<td>C</td>
<td>D</td>
<td>E</td>
<td>F</td>
</tr>
<tr>
<td>Enter &quot;Tube&quot; OR &quot;Plate&quot; for type of sample container</td>
<td>Enter Barcode of sample tube OR normalization plate (case sensitive)</td>
<td>Enter &quot;T&quot; to indicate sample is in a tube OR well position (e.g., A1, B1...) of sample in normalization plate</td>
<td>Enter &quot;Amp1&quot; for the destination plate position on instrument deck</td>
<td>Enter the destination well position on the amp plate (e.g., C1, D1,...)</td>
<td>Enter &quot;PPF&quot; to specify amp kit</td>
</tr>
</tbody>
</table>

   ii. Click the Save icon, then Yes to keep the file as CSV format, and close the document without saving (Don’t Save) when prompted again.
4. This Nimbus setup method also requires a reagent worklist (RWL.csv) in the Desktop/Nimbus Worklists/Amp folder in order to run. This file specifies the reagents needed to prepare the master mix. Do not edit or move this file regardless of the manner of master mix preparation (see Appendix Table A).
5. Power on the Nimbus Workstation and open the Hamilton Run Control software from the Desktop.
6. Select File, then Open, and navigate to the C:\Program Files (x86)\HamiltonCompany\Methods\Nimbus folder and select AmpNimbus.med.
7. After the software has connected to the Nimbus, click the green play icon in the toolbar to start. Follow the on-screen prompts to complete the run.
   a. Select the type of plate setup: Amplification, then click OK.
   b. Tip check: Three Edit Tip Count windows appear one after another with the available 1000µL, 300µL, and 50µL tips highlighted, respectively. Verify that the tip check is accurate and click OK. If the check is not accurate on any screen, select or deselect those positions to reflect the actual placement of pipette tips on deck. Click OK to proceed.

IMPORTANT: Make sure there are enough tips to completely process the plate and that there is sufficient space for tip waste. If tips are exhausted during the run, this will cause a critical error and the entire run must be redone (see Appendix Table B).
   c. When prompted, type or scan the barcode or name of the amplification plate (using the amp log numbering convention, YY-NNN) and place in the Amp1 position of the instrument deck (see Appendix Figure 1).
d. If applicable and when prompted, type or scan the barcode or name of the normalization deep well plate (i.e., NormMMDDYYXX), and place it in the Norm1 position on the instrument deck. Make sure the worklist for this corresponding normalization plate is still in the Desktop\Nimbus Worklists\Dilutions folder.

e. If not already done so, place barcoded samples and/or controls in any of the Shift-N-Scan racks and load racks onto the instrument deck, either capped or uncapped at this point. Ensure all barcodes are visible through the opening in the tube holders.

f. The Nimbus then scans the barcoded samples in the Shift-N-Scan racks and displays all tubes that were successfully scanned in the Barcode Handler window. Samples from the worklist that were not scanned are listed in the “Barcodes Not Found” column. These missing sample barcodes can be scanned in manually by clicking on the corresponding location in the Barcode Handler screen and scanning the barcode with the handheld scanner. Alternatively, the sample name/barcode may be typed into the corresponding cell. When all worklist samples are represented, click OK to proceed.

g. The amp plate setup method provides an option for preparing the master mix. Keep in mind, extra master mix must be prepared for any “Manual Amp Prep” samples that are added to the plate after the Nimbus amp plate setup portion is complete.

i. Select No to manually prepare the master mix. Select this option if any samples are to be added to the plate manually after Nimbus amp plate setup is done. Account for those extra samples when preparing master mix. Place the prepared 2mL screw cap tube of master mix at position 1 of the reagent block. Click OK to continue.

ii. Select Yes to have the Nimbus prepare the master mix. This option works if there are no “Manual Amp Prep” samples to be added to the plate as the calculation will not account for those samples. Follow the method’s prompts to scan and place the following tubes of sufficient volume at the specified positions on the reagent block uncapped (see Appendix Figure 2):

   - an empty and uncapped 2mL screw cap tube for master mix at position 1
   - reaction mix at position 4; scan or type: RxnMix
   - primer mix at position 2; scan or type: PrmrMix

iii. After preparing the master mix, the method prompts the user to remove and vortex/spin down the master mix. Visually inspect that it is of sufficient volume and appropriate color. Return the master mix uncapped back at position 1 on the reagent block and click OK to continue.

h. The robot then proceeds to dispense the master mix. After every 32 wells of dispensing, the method prompts the user to spin down the master mix tube and return it to the reagent block.

i. When master mix aliquoting is finished, remove the amp plate from the instrument deck and visually inspect the volumes in each well. If any well is not uniform, rectify the issue by manually removing all liquid from that well and pipetting the correct amount of master mix (10µL for amplification setup) back into that well. Replace the plate when ready and click OK.

j. If sample tubes are not already uncapped, do so now.

k. The robot then transfers samples from sample tubes and/or a normalization plate to the amp plate.

l. When finished, a completed run screen appears. Press OK to finish the method.

8. Remove the amp plate from the instrument deck and inspect the wells again. If there is any doubt that a sample was incorrectly added, manually adjust it to the correct amount.

9. Close the Nimbus door and return when ready to clean up.

10. For any “Manual Amp Prep” samples, bring the plate to a PCR prep hood and use the shaded cells from the “Norm Amp Template” sheet as a guide in adding the remaining samples manually to the plate.

   a. Use the remaining prepared master mix (or prepare more if needed) and manually aliquot 10µL to the corresponding wells.

   b. Add 15µL of the manual amp prep sample to its corresponding well.

11. Seal the plate with MicroAmp clear adhesive film or strip caps and proceed to the thermal cycling process.

12. Return to the Nimbus work area to cap sample tubes and/or re-seal the normalization plate with the sealing mat. Store samples in a 4°C refrigerator.

13. Clean the instrument deck, exit out of the Hamilton Run Control software, and power off the Nimbus.

14. Return to the Desktop\Nimbus Worklist\Amp folder, move a copy of the “WL.csv” file into the Archive subfolder, and rename that copy to include the date and user initials.

VI. 3500 Setup

A. Scope/Principle/Purpose: This procedure describes the automated setup of amplified DNA samples for Capillary Electrophoresis (CE) by the Hamilton Nimbus liquid handling platform. The post-amp setup method provides prompts to load plates and reagents and includes an option to prepare the master mix. The instrument dispenses the master mix, followed by the transfer of allelic ladders and amplicons from a 96-well PCR plate into designated wells of a 96-well reaction plate for CE processing. The transfer of samples is dictated by an Excel-based worklist prepared by the user which specifies the amplicon plate, the sample source well position, and sample destination well position. Any direct amplification samples may be added to the plate before the CE plate is covered with a septa mat and further prepared before loading onto the 3500 for STR processing. The processed amplicon plate is re-sealed and stored appropriately.
B. Reagents:
   1. WEN 500 Internal Lane Standard (ILS)
   2. PowerPlex Fusion 6C Allelic Ladder
   3. Hi-Di Formamide

C. Equipment and Supplies:
   1. Hamilton Microlab Nimbus Workstation
   2. Plate centrifuge
   3. 96-Well Reaction Plate
   4. MicroAmp Clear Adhesive Film, Strip Caps, or Strip Cap Mat
   5. 96-Well Plate Septa Mat
   6. 2.0mL Microcentrifuge tube

D. Procedure:
   1. Thaw the appropriate kit reagents and Hi-Di, if necessary, and thoroughly vortex reagent tubes.
   2. Ensure the amplification plate is labeled with the appropriate barcode or identifying information.
   3. Create a CE setup worklist using the DNA sample setup workbook or create a worklist manually. Worklists for 3500 plate setup must be in *.xls (Excel 97-2003 Workbook) file format and in the Desktop\Worklists\CE Setup folder for the method to run.
      a. To create a worklist from the DNA workbook, follow the "Instructions" tab to copy the relevant cells from the "3500 WL" sheet; paste those cells into a new Excel worksheet; rename the sheet tab to from "Sheet1" to "WL"; clear contents of empty cells; and finally Save As with the following name and file extension: WL.xls. When ready for Nimbus setup, move the worklist to the above specified folder on the post-amp Nimbus computer.
      b. To create a worklist manually on the post-amp Nimbus computer:
         i. Open the “WL.xls” file located in the Desktop\Worklists\CE Setup folder. Enter information for each sample or Allelic ladder per row as follows:
            |   |   |
            | A | B | C |
            | Enter Barcode (or name) of Amp plate (case sensitive) | Enter the sample well position from amp plate (e.g., C1, D1,...) | Enter the sample destination well position for the CE plate (e.g., C1, D1,...) |
            | Ladder (to add an allelic ladder) | 21 (this is the reagent block position where the allelic ladder tube is placed) | Enter the destination well position for the ladder on the CE plate (e.g., B1, C1,...) |
         ii. Ensure blank cells are free of formatting by selecting all blank cells, right click and select Delete.
         iii. Click Save and close the document.
   4. Power on the Nimbus Workstation and open the Hamilton Run Control software from the Desktop.
   5. Select File, then Open, and navigate to the C:\Program Files (x86)\HamiltonCompany\Methods\Nimbus folder and select PostAmp-Nimbus.med.
   6. After the software has connected to the Nimbus, click the green play icon in the toolbar to start. Follow the on-screen prompts to complete the run.
      a. Populate the Amp Plate field with the barcode/name of amp plate; this is the same input field as the Amp Plate Name from the "3500 Worksheet." This must match column A from the worklist.
      b. Populate the Load Plate field with the CE run name (DY-NNN).
      c. Tip check: Three Edit Tip Count windows appear one after another with the available 1000µL, 300µL, and 50µL tips highlighted, respectively. Verify that the tip check is accurate and click OK. If the check is not accurate on any screen, select or deselect those positions to reflect the actual placement of pipette tips on deck. Click OK to proceed.
         IMPORTANT: Make sure there are enough tips to completely process the plate and that there is sufficient space for tip waste. If tips are exhausted during the run, this will cause a critical error and the entire run must be redone (see Appendix Table B).
      d. Place a 96-well reaction plate in the “CE Plate” position of the instrument deck. See Appendix Figure 3.
e. The 3500 setup method provides an option for preparing the master mix.
   
i. Select **No** to manually prepare the master mix. Select this option if any direct amp samples are to be added to the plate manually after Nimbus CE plate setup is done. Account for those extra samples when preparing master mix. Place the prepared 2mL dolphin tube of master mix uncapped at position 1 of the reagent block. See Appendix Figure 2. Click **OK** to continue.
   
   ii. Select **Yes** to have the Nimbus prepare the master mix. This option works if there are no direct amp samples to be manually added to the plate as the calculation will not account for those samples. Follow the method’s prompts to place the following tubes of sufficient volume at the specified positions on the reagent block uncapped (see Appendix Figure 2):

   - an empty 2mL dolphin tube for master mix at position 1
   - WEN 500 ILS at position at position 3
   - Hi-Di formamide at position 4

   iii. After preparing the master mix, the method prompts the user to remove and vortex/spin down the master mix. Visually inspect that it is of sufficient volume. Replace the master mix uncapped back at position 1 on the reagent block and click **OK** to continue.
   
f. The robot then proceeds to dispense the master mix. When finished, remove the CE plate from the instrument deck and visually inspect the volumes in each well. If any well is not uniform, rectify the issue by manually removing all liquid from that well and pipette 10µL back into that well. Replace plate when ready and click **OK**.
   
g. Vortex and spin down the allelic ladder and place it uncapped at position 21 on the reagent block (see Appendix Figures 2 & 3). Click **OK** to continue.
   
h. The robot then transfers allelic ladder to designated wells of the CE plate.
   
i. Place the amplicon plate unsealed in the "Amp Plate" position on the instrument deck. See Appendix Figure 3.
   
j. The robot then transfers amplicons from the amp plate to the CE plate.
   
k. When finished, a completed run screen appears. Click **OK** to finish the method.

7. Remove the CE plate from the instrument deck.
   
8. Close the Nimbus door and return when ready to clean up.
   
9. If there are any direct amplification samples that are to be added to the plate, do so now. Use the shaded cells from the "3500 Worksheet" as a guide in adding the direct amp samples manually to the CE plate.
   
   a. Use the remaining master mix (or prepare more if needed) and manually aliquot 10µL to the corresponding wells.
   
   b. Add 1µL of the direct amplicon to the corresponding well.

10. Cover the CE plate with a septa mat. Balance and centrifuge the CE plate and proceed to heat denature and snap cool procedures before loading onto the 3500 autosampler for STR processing.

11. Return to the Nimbus work area to cap reagent tubes and reseal the amp plate. Store in a 4°C refrigerator.

12. Clean the instrument deck, exit out of the **Hamilton Run Control** software, and power off the Nimbus workstation.

13. Return to the **Desktop\Nimbus\CE Setup** folder, move a copy of the "**WL.xls**" file into the **Archive** subfolder, and rename that copy to include the date and user initials.

END OF DOCUMENT
Purpose

- Participation in CODIS requires that the laboratory follow guidelines set forth by the NDIS Operational Procedures. In the event there is a discrepancy between FBI's NDIS Operational Procedures and FBI's Quality Assurance Standards (QAS), the QAS has precedence and supersedes any of the provisions in the NDIS Procedures.
- The purpose of this manual is to provide guidance regarding procedures and practices pertaining to CODIS. A list of documents and manuals that may have bearing on the practices of the laboratory related to the operation of CODIS are below:

References

ASCLD/LAB Accreditation Manual Criteria
FBI Director's Quality Assurance Standards for Forensic DNA Testing Laboratories
NDIS Operational Procedures Manual
NDIS Security Requirements
FBI's CODIS Training Manual
CODIS Administrators Handbook
Biology Technical Unit Manual
California Penal Code, Sections 295 - 300
DNA Identification Act of 1994

1. The acronym CODIS stands for the Combined DNA Index System and is administered by the FBI. CODIS is composed of Offender, Casework, and Missing Persons databases and functions to provide investigative leads for the criminal justice system. It can link DNA evidence from a crime scene to an offender or to another crime scene. It can also link DNA evidence from missing person cases to references and/or relatives.
2. There are three levels of CODIS: The range of responsibility and authority associated with CODIS is dependent with the level of use.
   1. **LDIS** is the Local DNA Index System, the level at which CODIS is typically used by individual crime laboratories.
   2. **SDIS** is the State DNA Index System, the level at which CODIS is used by the State to serve as a state's DNA database. The State maintains eligible DNA profiles from each of the LDIS laboratories and is the gateway to **NDIS**, the National DNA Index System.
   3. **NDIS** is the National DNA Index System, a database of DNA profiles uploaded by each of the States. NDIS is the highest level in the CODIS hierarchy and is managed by the FBI. NDIS enables each laboratory within the CODIS system to exchange and compare DNA profiles at the national level.
3. The DNA Identification Act of 1994 et. seq. specified the Federal Bureau of Investigation as the oversight authority of NDIS, the CODIS network and its software. The DNA Identification Act also specified the allowable uses for CODIS. To show compliance with this act, the FBI issued procedural guidelines in the NDIS Operational Procedures Manual for State and Local laboratories to follow in order to have and maintain access to the CODIS system.
4. The NDIS Procedures Manual incorporates the FBI Director's Quality Assurance Standards. This manual is maintained at the FBI's CODIS website and is publicly available. Refer to website for the most up-to-date version of the NDIS Operational Procedures.

END OF DOCUMENT
1. The purpose of this document is to provide insight and reference legislation regarding Federal and State authority regarding DNA databases.
2. The Laboratory will follow applicable Federal and State law regarding DNA databases by complying with the Federal DNA Identification Act of 1994, as amended, as well as with California State DNA database laws.

Federal Legislation

1. Refer to the following documents found on the CODIS web site, located on the FBI Criminal Justice Information Services Shared Enterprise Network (CJIS SEN), for a complete review of the following:
   2. Privacy Act Notice for the National DNA Index System, July 18, 1996, Federal Register Vol. 61, No. 139
   3. Federal DNA Advisory Board Resolution (NDIS Operational Procedures)
2. The following is a summary of the DNA Identification Act and the changes made to the Act by the Justice for All Act of 2004:
   1. The DNA Act specifies the categories of data that may be maintained at the National index:
      1. DNA Identification records from:
         1. persons convicted of crimes
         2. persons who have been charged in an indictment or information with a crime.
         3. persons who DNA samples are collected under applicable legal authorities.
         4. DNA samples recovered from crime scenes.
         5. DNA samples recovered from unidentified human remains.
         6. DNA samples voluntarily contributed from relatives of missing persons.
   2. The DNA Act specifies that DNA records and DNA analyses offered to the National Index comply with the following:
      1. Analysis is performed by or on behalf of a criminal justice agency in accordance with the Quality Assurance Standards issued by the FBI Director.
      2. Prepared by a laboratory that is accredited by a nationally recognized accrediting body, such as ASCLD/Lab and undergoes external audits every 2 years to demonstrate compliance with the Quality Assurance Standards.
      3. Disclosure of DNA records only:
         1. To criminal justice agencies for law enforcement identification purposes
         2. For criminal defense purposes, to a charged defendant in connection with the case
         3. For other forensic purposes, such as population statistics, quality control purposes, and forensic research, if personal identifying information is removed.
   3. The Federal Privacy Act of 1974 requires that Federal agencies publish a notice whenever a new system of record is being established. The U.S. Department of Justice submitted a Notice to the Privacy Act regarding the National DNA Index System which was published on July 18, 1996. The Notice provides specific details and requirements that NDIS participation laboratories should be familiar with such as:
      1. Categories of individuals covered by the system (i.e. convicted offenders, missing persons…)
      2. Definitions of records in the system (i.e. DNA sample, DNA profile, DNA record…)
      3. Definition of indexes (i.e. Forensic Index, Convicted Offender Index…)
      4. The purpose of NDIS
      5. Disclosure of DNA Records as stated in the Federal DNA Identification Act
      6. Safeguards
      7. Retention and Disposal
4. Federal DNA Advisory Board Resolution (Resolution on Review of Privacy Issues)
   1. The Board reviewed the access and disclosure provisions provided by the DNA Identification Act of 1994. The Board agreed with the FBI's interpretation of the access provisions and supports the current level of enforcement of such access and disclosure provisions.
   2. The Board made recommendations that State laws provide for confidentiality of DNA records/samples that comply with the Federal DNA Act. Of concern are those states that appear to have more permissive laws for access to their DNA data. Compliance with the Federal DNA Identification Act will be audited by the Department of Justice Office of Inspector General.
California State Legislation

1. The DNA Act of 1998 (Pen. Code, §§ 295) was expanded in November 2004 with the passage of Proposition 69 which authorized the collection of DNA samples for databank purposes from adults or juveniles, who are convicted or found not guilty by reason of insanity for any felony offense, or any juvenile who is adjudicated under Section 602 of the Welfare and Institutions Code for committing any felony offense (Penal Code section 296).

2. Effective January 1, 2009, any adult arrested for or charged with any felony offense is subject to DNA sample collection. Additional information regarding DNA database collection can be found at ag.ca.gov/bfs/prop69.php.

3. CA. COLD HIT GRANT AND STATUTE OF LIMITATIONS ON 290 PC CRIMES
   Refer to Sections 800 of the California Penal Code for Statue of Limitations and to Section 803 subdivision (h) for changes to the statue of limitations on PC 290 related crimes. Below is a summation of Section 803(h):

   1. For offenses committed prior to January 1, 2001 where the statue of limitations (6 years) has not expired as of January 1, 2001, the statue of limitations on commencing prosecution shall be extended to 10 years from the date of the offense or one year from the date on which the identity of the perpetrator is conclusively established by DNA testing, whichever is later. **NOTE:** Under these conditions, the one year period applies only when the biological evidence has been analyzed for a DNA profile no later than January 1, 2004.

   2. For offenses committed on or after January 1, 2001, the statue of limitations shall be 10 years or one year from the date on which the identity of the perpetrator is conclusively established by DNA testing, whichever is later. **NOTE:** Under these conditions, the one year period applies only when the biological evidence is analyzed for a DNA type no later than two years from the date of the offense.

   3. **CA Proposition 69, Penal Code Section 297:** allows for the upload and search of DNA reference profiles from named individuals who are suspects and potential perpetrators in an active criminal investigation.

END OF DOCUMENT
### Purpose
To list the requirements, responsibilities of the laboratory, and to describe the security measures taken by the laboratory to show compliance with the NDIS Security Requirements manual available on the CJIS SEN.

### Laboratory Requirements
Requirements for a laboratory to qualify as an NDIS participating laboratory are addressed in the DNA Quality Assurance Standards. Thus, an audit using the Quality Assurance Standards is a tool that can be used to show that the laboratory is in compliance with these requirements. The Laboratory meets the following operational requirements to be an NDIS participating laboratory:

1. The laboratory is a Criminal Justice Agency.
2. The laboratory is accredited.
3. The laboratory adheres to the FBI Director's Quality Assurance Standards for Forensic DNA Laboratories.
4. The laboratory has more than the minimum employment of two qualified DNA analysts and is capable of performing DNA analysis of forensic casework.
5. The laboratory has a full-time, qualified Technical Leader.
6. The laboratory has a qualified, on-site, casework CODIS Administrator.

### Laboratory Responsibilities
1. The laboratory complies with FBI requirements to safeguard against unauthorized use of CODIS by providing a secure site for the computer. See below for discussion on Laboratory Security.
2. The laboratory maintains computer hardware and commercial software needed to access NDIS and to properly operate the CODIS system. This is done with the assistance of Sheriff's Office IT.
3. The CODIS Administrator will, if necessary, make suggestions for software enhancements for user efficiency and recommendations on procedural changes to the FBI.
4. The Supervisor and/or the CODIS Administrator will designate training for the appropriate personnel.
5. The CODIS Administrator notifies CODIS users of revised NDIS Operational Procedures.
7. The laboratory complies with all NDIS Operational Procedures for entering, verifying and expunging DNA records. See BIO.3.CODIS.06 for eligibility and expungement of DNA profiles.
8. The Laboratory maintains records of casework, audits and proficiency testing of CODIS users according to FSD Policy. The CODIS Administrator maintains specific records pertaining to the operation of CODIS and CODIS users.
9. The DNA Technical Lead will monitor and ensure that any vendor laboratory producing DNA profiles for upload to CODIS complies with the QAS document and meets NDIS eligibility requirements.
10. The Laboratory will participate in Office of Attorney General assessments. See BIO.3.CODIS.04 for audits and assessments.
11. The Laboratory takes responsibility for the costs associated with participation in NDIS:
   1. Salary and benefits for personnel employed to operate the CODIS system.
   2. Physical space (and if necessary, any modifications thereto) to accommodate the CODIS system, including operating expenses in connection with that space, such as electric, heat, and air conditioning.
   3. Computer hardware and commercial software (including any necessary maintenance) needed to access NDIS and properly operate the CODIS system.
   4. Travel, personnel and other related expenses for FBI or contractor staff if requesting an installation or move of a CODIS server and the laboratory has already had one install or move of a CODIS server in a ten year period.

### Laboratory Security
The laboratory provides a secure location for the CODIS computer to ensure safeguards are in place against unauthorized use of CODIS. The following security measures are implemented at the laboratory to safeguard the CODIS computer:
PERSONNEL

1. Access to the CODIS computer and its software is restricted to individuals who have passed a background check and who have been cleared by the FBI. This is limited to CODIS Users/Administrators and CODIS IT Users, who are employees of the Sheriff's Office, and who have passed a background investigation through the Office of the Sheriff.
2. Only CODIS Users are given a CODIS user account that includes a unique user account and password that allows access to the CODIS software. The CODIS computer is set to notify users of the need to change their passwords every 90 days.
3. CODIS Users must lock the computer or log off when they can no longer observe the CODIS computer or when they are finished. The CODIS room is located in the Forensic Biology Section. The Biology Section is a restricted access area. Note: The CODIS computer is set to lock after ten minutes of non-use and requires the user's password to unlock the computer.
4. A CODIS Contract User is exempt from the above security measures because a contract user does not have physical access to the CODIS computer.
5. An IT employee is permitted access to CODIS for computer hardware/software and telecommunications maintenance purposes and may be added as a CODIS IT user. Because this user has physical access to CODIS, an FBI security check is required (in addition to any security checks performed by the employing governmental agency). A CODIS IT user is not authorized to add, modify or delete DNA records in CODIS.

PHYSICAL SECURITY

1. The CODIS server and CJIS SEN router is located in the CODIS room. This room is located behind the restricted key-card access area of the Forensic Biology Section.
2. A full backup of the CODIS data is conducted weekly with incremental backups conducted daily. The last two most recent full backups are stored off-site in two separate locations within the Sheriff's Office. The backups are rotated on and off-site in cooperation with Sheriff's Office Technical Support.
3. The CODIS Administrator and/or Alternate administrator works with Technical Support to perform periodic restores to ensure backups are working properly.

CONTINGENCY PLAN

In the event that a catastrophic event or emergency occurs that affects the operation of the CODIS server and CJIS SEN connection, the laboratory will work with the Sheriff's Office Technical Support to re-establish the CODIS system which may include: replacing or salvaging the computer hardware and software and the data, relying on the backups, etc. CJIS and any other entities will be contacted to reestablish communication to the CODIS network.

CODIS COMPUTER SOFTWARE SECURITY

1. Access to the CODIS computer software is limited to CODIS Users as stated above. Only CODIS users are given login rights to access the CODIS software. Although IT users have physical access to the computer, they are not given access rights to the CODIS software. The laboratory works in cooperation with the Sheriff's Office Technical Services for maintenance, installation and upgrades to the CODIS computer.
2. Security related software upgrades/patches/fixes are applied by the CODIS Administrator and Alternate.

COMPUTER NETWORK SECURITY

1. The CODIS software is installed on a computer with no internet access. In the event of a change to this condition, the laboratory will follow the procedures outlined in the NDIS Operational Procedures and NDIS Security Requirements.
The purpose of this document is to describe the laboratory's responsibilities and procedures regarding audits and assessments relevant to CODIS.

1. The Office of the Sheriff's Crime Laboratory is considered an NDIS participating laboratory. To maintain this status, the laboratory must meet certain requirements. Compliance with the requirements is assessed through a DNA Quality Assurance Standards audit of the laboratory's DNA program and periodically through an NDIS Assessment. Access to the National DNA Index System is subject to cancellation if the Quality Assurance Standards are not met.

2. Additionally, the Office of the Inspector General (OIG) periodically will conduct an assessment of the laboratory's compliance with the NDIS Operational Procedures. An OIG audit can occur at any time.

Audits

1. A copy of the QAS external audit document is to be forwarded to the NDIS Custodian within 30 days of receiving the audit document back from the auditors. Responses to findings, or a list of measures actively seeking redress, should be included with the audit document. The original QAS audit document is retained by the Biology Unit under the guidance of the DNA Technical Lead.

2. A copy of both internal and external QAS audits is sent to the State CODIS Administrator in a timely manner.

3. Annually, the "Laboratory Audit Certification" form is forwarded to the State CODIS Administrator. The form is found on the CODIS website. A copy of the certificate is maintained by the CODIS Administrator.

4. Audit records and records pertaining to CODIS users, such as training, competency and proficiency tests are retained minimally for ten years.

5. The CODIS Administrator maintains, at a 10 year minimum, the following records related to CODIS users:
   1. A CODIS user's FBI clearance and any changes to a CODIS user's status. Forms are found on the CODIS website.
   2. A record (certificate or equivalent) of an analyst's successful completion of the annual DNA Records Acceptable at NDIS test.
   3. An analyst's CODIS training.

NDIS Assessments

1. The Laboratory's compliance with the NDIS Operational Procedures is periodically assessed through an NDIS Assessment. The assessment is a review of the Laboratory's CODIS program and is distinct and separate from an external DNA Quality Assurance audit. The FBI requires the laboratory to participate in the assessment.

2. The CODIS Administrator and/or Alternate are the primary points of contact during the assessment process. Applicable laboratory manuals will be subject to review as well as other CODIS related documentation. Refer to the NDIS Operational Procedures Manual for a full review of the NDIS Assessment procedure.

3. Some of the areas that will be under review include:
   1. CODIS user records
   2. Accreditation and audits
   3. Access and disclosure of records
   4. Expungement and eligibility of DNA profiles
   5. Laboratory policies/procedures/protocols

END OF DOCUMENT
I. CODIS users have different levels of access, authority, and responsibility. User training will be determined by their assigned role and responsibilities.

II. New Users

1. A new CODIS User is required to submit identification materials and pass a security check by the FBI, prior to gaining access to CODIS or the CJIS SEN. The necessary forms are found on the CODIS website.

2. The documents will be forwarded to the NDIS Custodian via the State CODIS Administrator, or alternatively directly to the NDIS Custodian with a cc to the State Administrator.

3. The documents should be accompanied by an appropriate cover letter (see CODIS website).

4. A copy of all documents will be retained prior to sending them to the State Administrator or NDIS Custodian.

5. Once the laboratory has been notified that the new user has passed the FBI's security clearance, the new user has 30 days to successfully complete the DNA Records Acceptable at NDIS training. The new user may not access the CJIS SEN or CODIS software before notification that the new user has passed the FBI's security check.

6. The DNA Records Training is available through LMS (Learning Management System) on the CODIS website. Upon successful completion of the training, the laboratory will be notified that the new user has been given access as a CODIS user and is now eligible to submit DNA profiles to NDIS.

III. CODIS IT Users

1. Sheriff's Office technical services personnel (IT users) must be cleared by the FBI with the same identification materials as required of a new user. The forms are found on the CODIS website. The IT Users are given physical access to the CODIS hardware, but they are not given access rights to the CODIS software or the CJIS SEN.

2. The Laboratory and Sheriff's Office IT personnel work together on maintenance, installation, and upgrades to the CODIS computer.

IV. CODIS Contract Users

1. The Sheriff's Office contract users are DNA analysts from a vendor laboratory who has generated a DNA profile for upload into CODIS. The vendor laboratory relies upon the Sheriff's Office to upload the profile into CODIS.

2. The DNA analyst must meet all the same QAS requirements as a qualified DNA analyst in an NDIS participating laboratory.

3. Contract users do not have physical access to the CODIS computer, thus a security clearance is not required. However, a CODIS User Information form along with a cover letter is routed to the NDIS custodian via the State CODIS Administrator. Refer to the CODIS Website for the CODIS User Information form and cover letter form.

V. CODIS User:

1. Requirements:
   a. A CODIS user must be an employee of a Federal, State, or Local government.
b. A CODIS user must be a qualified DNA analyst and maintain appropriate proficiency testing, as specified in the DNA Quality Assurance Standards (QAS 5.4).

c. A CODIS user must pass a security background check through the FBI prior to accessing CODIS or the CJIS SEN.

d. A CODIS user will receive in-house training on the CODIS software to the extent of what is relevant for the CODIS user's need.

e. Participate in the Annual Review of DNA Data Accepted at NDIS assessment.

2. Responsibilities:

a. The CODIS user may enter the DNA profiles from their own casework into CODIS (with the exception of the CODIS Contract User). The CODIS Administrator or Alternate may enter a profile on behalf of an analyst and mark the original analyst who generated the profile in the “assigned” section.

b. The CODIS user entering the profile will verify that the data entered is correct and document the verification by initialing and dating the printed Specimen Detail report.

c. The profile may also be added to the Biology Unit's internal database under "CODIS Profiles".

d. The laboratory will notify the client agency whenever a DNA profile is uploaded or deleted from CODIS or when there is a one-time search. This notification is generally documented in a laboratory report.

e. In the event of a CODIS Hit, the analyst who generated the profile or the CODIS Administrator or Alternate Administrator may write the CODIS Notification Report. The report serves as the Laboratory's record that the client agency was informed of the hit.

f. In the event that the CODIS Administrator or Alternate is unable to disposition a hit, due to the complexity of a match, the DNA analyst who generated the profile will be referred to. The analyst may find it necessary to refer to their original data to discern the proper disposition of the hit. When the original analyst is not available to discern the match, either the CODIS Administrator,Alternate, or an assigned analyst qualified to interpret mixtures will discern the proper disposition of the hit on behalf of the original analyst.

g. The DNA analyst who generated the DNA profile that subsequently generated a CODIS Hit will be assigned to conduct the DNA confirmation testing. Another DNA analyst may conduct the confirmation, on behalf of the original analyst when necessary.

VI. Casework CODIS Administrator

1. The CODIS Administrator is a user with administrative rights and privileges applicable to the CODIS computer, software and the laboratory's CODIS program. The CODIS Administrator is a single appointed position in the laboratory and has the responsibility and authority of overseeing the CODIS program. The Administrator has the authority to author and sign all correspondence and to ensure all required reports for the FBI and NDIS Custodian are prepared.

2. The Chief may appoint a new CODIS Administrator at any time, though the importance of stability in this position will be taken into consideration. The individual assigned may be selected from technical, supervisory, or management staff, depending on the needs of the Division.

3. Requirements:

a. Be an on-site employee of the laboratory (QAS 4.1.3).

b. Be or have been a qualified DNA analyst. This includes at least 6 months of Forensic Human DNA laboratory experience and documented mixture interpretation training (QAS 5.3). (Note: a CODIS Administrator appointed prior to the July 1, 2009 QAS document is deemed to have satisfied the education and experience requirements (grandfathered). This grandfathering is applied to the laboratory in which the CODIS Administrator is employed and is not portable with the employee.

c. Complete training with the newest version of the CODIS software within six months of assuming the Administrator role and duties (QAS 5.3.3). This training is provided by the FBI.

d. Complete the QAS Auditor Training sponsored by the FBI within a year of assuming the CODIS Administrator role or position (QAS 5.3.3).

e. Annually, have a minimum of 8 hours of continuing education (QAS 5.1.3.1).
f. Attend the annual National CODIS Conference sponsored by the FBI. If the CODIS Administrator cannot attend, the Alternate is to attend. If neither the CODIS Administrator nor the backup can attend, an excused absence from attendance must be obtained from the NDIS Custodian.

g. Obtain and remain security clearance with the FBI as a CODIS user.

h. Be qualified to disposition matches:
   
   i. A Candidate Match matching all loci at high stringency may be reviewed and evaluated by an individual who is currently or was previously a qualified DNA analyst.

   ii. A match at any loci at less than high stringency shall be reviewed and evaluated by a DNA casework analyst currently or previously qualified in the technology (such as RFLP, STR, YSTR) being reviewed.

4. CODIS Administrator's Responsibilities:

   a. Administer the Laboratory's CODIS network (QAS 5.3.4.1).

   b. Schedule and document CODIS computer training of casework analysts (QAS 5.3.4.2).

   c. Oversee compliance with CODIS security requirements (QAS 5.3.4.3).

   d. Ensure that the quality of data stored in CODIS is acceptable according to state/federal laws and the NDIS Operational Procedures (QAS 5.3.4.4).

   e. Ensure matches are dispositioned according to NDIS Operational Procedures (QAS 5.3.4.5).

   f. Remove an analyst's or the laboratory's participation in CODIS in the event of an issue that questions the reliability and security of the data (QAS 5.3.5).

   g. Note: In the event that the CODIS Administrator and Alternate positions becomes unoccupied, the laboratory will suspend uploads until a new casework CODIS Administrator is appointed (QAS 5.3.6).

   h. Notify the NDIS Custodian, within five business days, of the following (NDIS Operational Procedures):

      i. If a CODIS User or CODIS IT User in their laboratory has been arrested for, or convicted of, a criminal offense

      ii. If the laboratory loses accreditation status

      iii. If the laboratory loses the capability to perform DNA analysis at its facility.

      iv. If the laboratory has fewer than two full-time DNA analysts

      v. If the laboratory has a vacancy in the laboratory's Technical Leader position and there is no one in the laboratory who meets the QAS qualifications or available to serve in the position.

VII. Alternate CODIS Administrator is a CODIS user designated by the CODIS Administrator who has been given administrative rights and privileges to assist the CODIS Administrator and to fulfill the CODIS Administrator's role when absent or unavailable.

1. Requirements:

   a. An Alternate CODIS Administrator needs to be designated by the CODIS Administrator within ninety (90) days when the Alternate CODIS Administrator position becomes vacant. In the event that a Alternate CODIS Administrator is not designated within ninety (90) days, the NDIS Custodian needs to be notified.

   b. The Alternate CODIS Administrator needs to successfully complete the QAS auditor training sponsored by the FBI within 1 year of assuming the role.

   c. The Alternate CODIS Administrator needs to successfully complete the newest version of the CODIS software training within 6 months of assuming the role. This training is provided by the FBI.

VIII. CODIS Administrator and Alternate Administrator's Duties

1. Be the laboratory's points of contact for the CODIS program and serve as the gatekeeper for the DNA data entered into CODIS

2. Review CODIS Bulletins and changes to NDIS Operational Procedures, and implementation, if applicable.
3. Maintain hardware, software, and CODIS updates.

4. Ensure **weekly** backups of the CODIS computer are conducted.

5. Conduct a periodic restore of the backup data to ensure backups are working properly.

6. Conduct incremental and full uploads to SDIS.

7. Review of Reconciliation Reports.

8. Add/Remove/Update CODIS Users

9. **Ensure the Quality of DNA Results**
   
a. Ensure all User(s) have successfully completed the following requirements:
   
   i. Annual training on DNA Data Acceptable at NDIS
   
   ii. A competency test prior to being assigned casework.
   
   iii. A proficiency test taken within six months of start of casework.
   
   iv. Two proficiency tests completed per year. (Note: The DNA Technical Lead will inform the CODIS Administrator when a non-administrative discrepancy in a proficiency has occurred and at the time of initiating a corrective action and cite the nature of the discrepancy).
   
   v. Verify with the Technical Leader that standard (QAS 17) has been met for any vendor laboratory used by the laboratory.
   
   vi. Ensure all CODIS qualified profiles have undergone technical review and have been entered into CODIS correctly.
   
   b. Disposition
   
   i. Review and make best efforts to disposition matches within 30 business days.
   
   ii. Ensure proper disposition of CODIS matches and hits.
   
   iii. Verify Conviction matches.
   
   c. Records
   
   i. Maintain records of CODIS users
   
   ii. A CODIS user's FBI clearance
   
   iii. A CODIS user's completion of the annual DNA Records Acceptable at NDIS test
   
   iv. CODIS user's Local CODIS training
   
   v. Update CODIS user information
   
   vi. Laboratory Audit Certification Form
   
   vii. Annually provide internal and external audit documents to State CODIS Administrator
   
   viii. Provide external audit documents to NDIS Custodian
   
   ix. Annual Update of the Points of Contact to State CODIS Administrator
   
   x. CODIS Survey document
   
   xi. Update any internal databases, such as "CODIS Profiles" and "CODIS Hits" located on the Biology Unit's network folder.
   
   xii. Removal of suspect profiles after 2 years.
   
   d. Reporting
i. Ensure reports are generated for CODIS Hits/Matches, Keyboard Searches (SDIS and NDIS), and deleted profiles.

ii. Administrative review of CODIS Hits/Matches, Keyboard Searches (SDIS and NDIS), and deleted profiles. The Administrative reviewer's milestone in LIMS documents completion of both technical and administrative review.

iii. Enter and update required data into California's CODIS Hit Outcome Project (CHOP) website.

iv. The CODIS Administrator and Alternate Administrator may write or administratively review CODIS Notification Reports.

e. Security

i. Ensure FBI background clearance of users.

ii. Ensure security of the CODIS computer through personnel, physical, and computer measures that limit access to CODIS.

f. Training

i. Train and/or oversee training of new CODIS users.

ii. Ensure CODIS Analysts complete the Annual Review of DNA Data Accepted at NDIS training.
Documented Technical Review

All DNA casework is technically reviewed. The parameters of the technical review can be found in the DNA Technical and Administrative Review checklist (BIO.1.BIOF.02). Prior to data entry into CODIS, the supporting examination records are technically reviewed. The analyst and technical reviewer verify the following information on the case file's Summary Data Sheet prior to upload (QAS 12.2.7):

1. Correct DNA types
2. Eligibility for CODIS (see below)
3. Correct specimen name and category. See also BIO.3.CODIS.07 for selecting correct specimen categories.
4. Offense and offense date
5. Agency and agency case number

Verification Prior to Upload

The CODIS Administrator or Alternate verifies that the profile has been technically reviewed and verifies that the information entered into the STR Data entry fields is correct when cross-referenced with the case file’s Summary Data Sheet. Verification by the administrator is recorded on a copy of the analyst's Summary Data Sheet with the initials and date of the administrator. The Summary Data Sheet copy is maintained in a binder near the CODIS computer.

Eligibility Requirements

1. The laboratory follows the FBI's decision-making flowchart (see CODIS Administrator’s Handbook on the CJIS SEN) to determine if a DNA profile developed from casework is eligible for upload into CODIS. A copy of the flowchart is kept by the CODIS computer for quick referencing.

2. NOTE: The NDIS Procedures state that for those cases not easily resolved through the guidance provided in the flowchart and/or the provided scenarios, it is important to document your reasoning for determining eligibility. This documentation will be made in the case notes. The CODIS Administrator's Handbook may also provide assistance with difficult scenarios.

3. The profile is verified to be interpretable, meaning the data can be used to make exclusions.

4. Only alleles attributed to the putative perpetrator(s) are offered into CODIS (where possible). In cases where there is ambiguity in the assigning of alleles to the putative perpetrator(s), the profile is not precluded from being entered into CODIS.

5. Alleles clearly attributed to a victim or individual other than the perpetrator(s), such as, a consenting partner will not be offered to CODIS. (See Expungement of Elimination Samples below).

6. Forensic profiles for search require a minimum number of original core loci and meet a moderate match estimation (MME) threshold per level of database search. This must be done for all categories except Forensic Unknown. For SDIS, the profile must contain at least 7 loci and meet a minimum MME of one in one million (note: MME is only calculated using original 13 loci plus D2 and D19). For NDIS, the profile must have at least 8 of the original core loci and meet a minimum MME of one in ten million. Forensic profiles that do not meet the minimum MME maybe re-categorized in to Forensic Targeted where the profile must have at least 8 of the original core loci and meet a match rarity estimate (MRE) of one in ten million. The "Match Estimation" utility in CODIS or an equivalent program can be used to...
calculate the MME or MRE.

7. A Composite DNA profile is a profile generated by combining typing results from different loci obtained from multiple injections of the same amplified sample and/or multiple amplifications of the same DNA extract. When separate extracts from a given evidentiary item are combined prior to amplification, the resulting DNA profile is not considered a composite profile. Unless there is a reasonable expectation of sample(s) originating from a common source (e.g. duplicate vaginal swabs, known reference samples, or a bone), allelic data from separate extractions from different locations on a given evidentiary item should not be combined into a composite profile. The quality and/or the number of contributors in the profile will determine which specimen category and index the profile will be stored.

LDIS Specimens Eligible for Upload to SDIS and/or NDIS (see BIO.3.CODIS.08 for definitions):

1. Forensic Mixture
2. Forensic Partial
3. Forensic Unknown
4. Forensic Targeted
5. CA Partial (CA SDIS only)
6. CA Mixture (CA SDIS only)
7. Unidentified Human Remains
8. Biological Relatives (Mother, Father, Child, Sibling) / Pedigree Tree
9. Legal

Ineligible Specimens:

1. LCN/LT (Low Copy Number/Low Template) DNA Analysis: A subset of Enhanced Detection Methods that, in addition to the increased potential for stochastic effects, have an increased potential for non-reproducible alleles.

2. Possession Offenses: Forensic samples related to possession offenses, such as a felon in possession of a firearm can be difficult to discern. DNA profiles developed from possession offenses when the item was removed directly from the person typically are best categorized as a deduced suspect profile and cannot be uploaded to NDIS. The State Administrator or NDIS Custodian may be contacted to help further discern the profiles eligibility for upload.

3. *Elimination samples: victim, consensual partner, etc.

*The laboratory shall make a good faith effort to obtain elimination samples from the law enforcement agency. The request for such samples will be documented in the examination record and shall be requested prior to entering the forensic unknown profile into CODIS. See section below on Expungement of Elimination Samples.

Amplification Kits
The laboratory uses kits approved by NDIS to produce DNA profiles for entry into CODIS. Refer to the NDIS Operational Procedures for a current list of approved amplification kits.

The laboratory strives to amplify the 20 CODIS core loci, of which are part of the PowerPlex Fusion 6C kit. SDIS and NDIS accepts Y-STR data, however, they are not searched. Y-STR profiles are generated with the PowerPlex Y23 kit, of which all loci are accepted. Y-STR will be entered as additional information for eligible Familial Search specimens. See BIO.3.CODIS.08 for the required and accepted loci and MME requirements per specimen category for upload and autosearch.

Acceptance of DNA Profiles from a Vendor Laboratory
Refer to the Biology Technical Unit Manual BIO.5.QAQC.17 for a complete review of the laboratory's requirements and procedures when working with a Vendor Laboratory.

Expungement of DNA Records from CODIS

1. State or local DNA records are maintained at SDIS/NDIS as long as they are substantiated by the internal records of the laboratory and are allowed to be retained by Federal or State law, by judicial decree or by consent. State or local DNA records can be deleted if the laboratory determines that the record is no longer lawfully permitted or appropriate for retention in the system.

2. If a DNA record is deleted from the database (removed from routine search), the event of an upload will record the deletion at SDIS and NDIS as well. A reconciliation report is sent to the laboratory through CODIS. The reconciliation report is printed and retained. The reason for the deletion is recorded on either the recon report or the Specimen Deletion report. The law enforcement agency is informed via a written report or an equivalent document about the deletion of the profile and the documentation is maintained in the case file.

Legally Obtained Suspect Known (LOSK) Profiles
A legally obtained suspect known profile must be removed from SDIS after 2 years, unless written notification is provided from the law enforcement agency that the named suspect is still a suspect in an on-going criminal investigation. After two years, the profile can either be unmarked for upload or deleted from LDIS. If the suspect has a profile in the State Offender database, the profile may be deleted. If deleted, a deletion report notifying the agency that the "suspect" profile of the deletion will be written.
Elimination Profiles

Profiles associated with victims, consensual partners, etc. are not allowed for CODIS upload. Effort is made to avoid entering these types of profiles into CODIS. However, there are instances where elimination samples from a victim, boyfriend, etc. could not be obtained from the law enforcement agency prior to the upload of the forensic unknown profile.

In the event an elimination sample is received and found to match the forensic unknown, after the forensic unknown has been uploaded, the forensic unknown will be removed from the database.

In the event a CODIS Hit occurs and the named Offender/Arrestee is determined to match an elimination person, the forensic unknown will be removed from CODIS.

END OF DOCUMENT
I. The purpose of this document is to define and clarify the types of specimens that can be stored, uploaded and searched at the LDIS, SDIS and NDIS levels and the appropriate indexes for which the specimens are stored.

1. The NDIS Operational Procedures define the types of specimens allowed to be stored and searched at NDIS as well as the indexes for which the allowable specimens are to be stored and searched.

2. State and local laboratories may store and search specimens in CODIS for other categories such as suspect, victim, quality control specimens (such as staff member's profiles) and other elimination specimens, in accordance with State Database Laws (see section on Federal and State Legislation, BIO.3.CODIS.02). States look to their own DNA database laws for determining the categories of DNA data that can be stored and searched at the State level.

3. A laboratory's failure to comply with the NDIS authorized categories of DNA records may result in the suspension or termination of that laboratory's access to NDIS in accordance with the DNA Identification Act of 1994.

4. See BIO.3.CODIS.08 for a description of the type of searches that can be conducted at the local level and their associated procedures.

II. Specimen Category vs Specimen Index

4. Indexes Searched

a. Searches in CODIS can be conducted at three levels: Local, State, and National. Refer to the NDIS Operational Procedures for searches conducted at the NDIS level. The laboratory searches its own profiles against its own database indexes. The search compares the new profile ("Target") against the panel of older ("Candidate") profiles already in the database. As a specimen is added to an index, the specimen is searched against other specimens in the same index, as well as, against other specimens in other indexes (Forensic Unknown, Forensic Mixture, Forensic Partial, CA Partial, CA Mixture, Staff, Legal, and Unidentified Human).

b. Settings for each search can be viewed on the Search Configuration tab in Match Details or in the Match Details Report.

**Glossary (as defined by the NDIS Procedures Manual)**

**Arrestee (Specimen Category)** - The known sample from a person who has been arrested and in accordance with the law of the applicable jurisdiction is required to provide a DNA sample for analysis and entry into a state DNA database. The term “arrestee” includes persons who have been charged in a formal criminal instrument, such as an indictment or an information. The DNA record for this specimen category is stored in the Arrestee Index.

**Arrestee Index** - An Arrestee Index consists of DNA records of persons who have been arrested or indicted or charged in an information with a crime and are required by law to provide DNA samples.

**Biological Child (Specimen Category)** - The known reference sample voluntarily provided by an adult child or provided with the parental/guardian consent for a minor child of a reported missing person. The DNA record for this specimen category is stored in the Relatives of Missing Person Index and the Pedigree Tree Index.

**Biological Father (Specimen Category)** - The known reference sample voluntarily provided by the biological father of a reported missing person. The DNA record for this specimen category is stored in the Relatives of Missing Person Index and the Pedigree Tree Index.

**Biological Mother (Specimen Category)** - The known reference sample voluntarily provided by the biological mother of a reported missing person. The DNA record for this specimen category is stored in the Relatives of Missing Person Index and the Pedigree Tree Index.

**Biological Sibling (Specimen Category)** - The known reference sample voluntarily provided by the full or half biological adult sibling or provided with the parental/guardian consent of a full or half biological minor sibling of a reported missing person. The DNA record for this specimen category is stored in the Relatives of Missing Person Index and the Pedigree Tree Index.

**Convicted Offender (Specimen Category)** - The known sample from a person who has been convicted of a Federal, Military or State qualifying offense in a jurisdiction that requires that persons convicted of enumerated crimes or qualifying offenses provide a DNA sample for analysis and entry into a Federal, Military or State DNA database. The DNA record for this specimen category is stored in the Convicted Offender Index.

**Convicted Offender Index** - A Convicted Offender Index consists of DNA records from offenders convicted of qualifying State crimes and juveniles required by the relevant jurisdiction to provide DNA samples.

**Deduced Missing Person (Specimen Category)** - The DNA profile of a reported missing person that has been generated by examining intimate items purported to belong to the missing person such as a toothbrush, and compared to close biological relatives, if possible. Considered a reference sample, this DNA record is stored in the Missing Person Index.
Detainee (Specimen Category) - The known sample from a non-United States (U.S.) person detained under the authority of the U.S. and required by law to provide a DNA sample for analysis and entry into a State/national DNA database. The DNA record for this specimen category is stored in the Detainee Index.

Detainee Index - A Detainee Index consists of DNA records from non-United States (U.S.) persons detained under the authority of the U.S. and required by law to provide a DNA sample.

Forensic Index - A Forensic Index consists of DNA records originating from and associated with an evidence sample from a single source (or a fully deduced profile originating from a mixture) that is found at a crime scene. The Forensic Index contains Forensic Unknowns.

Forensic Mixture (Specimen Category) - A specimen category in the CODIS software that is stored in the Forensic Mixture Index and originates from a forensic sample (biological sample found at the scene of a crime) that contains DNA contributed from more than one source attributable to a putative perpetrator(s).

Forensic Mixture Index - A Forensic Mixture Index consists of DNA records from forensic samples that contain DNA contributed from more than one source. The Forensic Mixture Index contains Forensic Mixture DNA records.

Forensic Partial (Specimen Category) - A specimen category in the CODIS software that is stored in the Forensic Partial Index and originates from a single source (or a fully deduced profile originating from a mixture) Forensic Sample attributable to the putative perpetrator with either locus or allelic dropout at any of the 13 Original CODIS Core Loci. Effective January 1, 2017, an analysis of all CODIS Core Loci shall be attempted for Forensic Partial Samples.

Forensic Partial Index - A Forensic Partial Index consists of DNA records from forensic samples that do not contain results for all 13 Original CODIS Core Loci and/or that may indicate a possibility of allelic dropout.

Forensic Targeted (Specimen Category) - A specimen category in the CODIS software that is stored in the Forensic Targeted Index. A forensic targeted specimen originates from a forensic partial or a forensic mixture that does not meet the NDIS moderate match estimate threshold of 1 in 10 million, but does meet the match rarity estimate threshold of 1 in 10 million if searched at a specified stringency by locus (high or moderate).

Forensic Unknown (Specimen Category) - A specimen category in the CODIS software that is stored in the Forensic Index and originates from a single source (or a fully deduced profile originating from a mixture) Forensic Sample attributable to the putative perpetrator and contains results for all 13 Original CODIS Core Loci.

Juvenile (Specimen Category) - The known sample from a juvenile (as that term is defined by the relevant jurisdiction) who is required by State law to provide a DNA sample for analysis and entry into a State DNA database. The DNA record for this specimen category may be stored in the Convicted Offender Index.

Legal (Specimen Category) - The known reference sample from a person whose DNA sample is collected under applicable legal authorities (State law), provided that DNA samples that are voluntarily submitted solely for elimination purposes shall not qualify as a Legal specimen. The DNA record for this specimen category is stored in the Legal Index.

Legal Index - A Legal Index consists of DNA records of persons whose DNA samples are collected under applicable legal authorities (State law).

Missing Person (Specimen Category) - The known reference sample from an individual that is missing. The source of the DNA has been verified as originating from the missing person and is stored in the Missing Person Index.

Missing Person Index - A Missing Person Index consists of DNA records from missing persons and deduced missing persons.

Multi-allelic Offender (Specimen Category) - An offender (arrestee, convicted offender, detainee or Legal Index specimen) DNA record having three or more alleles at two or more loci.

Multi-allelic Offender Index - A Multi-allelic Offender Index consists of DNA records from offenders (arrestees, convicted offenders, detainees or Legal Index specimens) having three or more alleles at two or more loci.

Pedigree Tree - A Pedigree Tree contains genetic information from two or more biological relatives of missing persons (may include spouses, where applicable). A Single Typed Node Pedigree contains the genetic information from only one biological relative of the missing person.

Pedigree Tree Index - A Pedigree Tree Index consists of DNA records of biological relatives and spouses of missing persons that are associated with a Pedigree Tree.

Relatives of Missing Person Index - A Relatives of Missing Person Index consists of DNA records from the biological relatives of individuals reported missing.

Unidentified Human (Remains) Index - An Unidentified Human (Remains) Index consists of DNA records from recovered living persons (e.g., children who can’t and others who can’t or refuse to identify themselves), and recovered dead persons (including their body parts and tissues) whose identities are not known.

Unidentified Person (Specimen Category) - The DNA profile developed from the recovered deceased (including body parts and tissue) or an individual who is unidentified (e.g., children who can’t and others who can’t or refuse to identify themselves). The DNA record for this specimen category is stored in the Unidentified Human (Remains) Index.
I. Introduction

A. The purpose of this document is to provide general instructions on the process of entering, uploading, and searching specimens at the local CODIS level (LDIS). It is not intended to capture all aspects or to replace the CODIS training provided by a CODIS Administrator or the FBI's CODIS training.

B. Profiles entered at the local level are searched against profiles in the LDIS database prior to upload to the State level. The profiles uploaded to the State are searched against the State database (SDIS) and subsequently uploaded to NDIS. The profiles will be searched against the NDIS database as long as the profiles meet the NDIS autosearch requirements (See below). Refer to section: Specimen Categories and Indexes Searched (BIO.3.CODIS.07). For more information on the category of specimens and their associated indexes, and section: Acceptance Standard, Eligibility, and Expungement (BIO.3.CODIS.06), for information on eligibility of specimens entered into CODIS.

II. Procedure for Data Entry

A. Prior to Data Entry:

1. The laboratory will make a good faith effort to obtain elimination samples (where warranted) from the law enforcement agency to prevent ineligible profiles from being uploaded to CODIS. The request for such samples shall occur and be documented prior to the forensic unknown being entered into CODIS. See section: Disposition of Candidate Matches (BIO.3.CODIS.09) for the disposition of a match to an elimination sample and section: Acceptance Standards, Eligibility, and Expungement (BIO.3.CODIS.06) for the expungement of elimination samples.

B. Procedure:

1. Log on to the CODIS computer using your CODIS user password.

2. Open the CODIS Analyst Workbench and select STR Data Entry. Fill in the following fields:

   a. Specimen name: the specimen name is a unique identifier of the DNA profile. The name of a specimen generally includes the Laboratory Case File number and specimen item designation. Other identifiers may be added such as: a cell fraction; "sperm" or a component; major/minor.

      Example A: 01-1111-2 1-1H SPERM = 01-1111-2 1-1H SP
                  (Lab Case No) (Item) (Fraction) (Specimen Name)

   b. Certain grant program samples have been entered using a grant specific numbering system:

      Example B: OCJP 000-100 1-1H SPERM = OCJP 000-001 1-1H SP
                  (Grant Number) (Item) (Fraction) (Specimen Name)

   c. A profile generated from a vendor laboratory may have additional identifiers indicating the vendor lab that generated the profile:

      Example C: FASI 01-1111-2 1-1H SPERM = FASI 01-1111-2 1-1H SP
                  (Vendor ID) (Lab Case No) (Item Designation) (Specimen Name)

   d. Specimen category: the specimen must be assigned an appropriate specimen category. See Specimen Categories and Indexes (BIO.3.CODIS.07).

   e. Assigned to: defaults to the CODIS User that is logged on. This field can be assigned to another CODIS user or contract user to track profiles generated by a DNA analyst.

   f. Source ID: (option: Yes, No, or NA) Select “Yes” if the source of the profile is known and “No” if there is no confirmation of the source. "NA" is not typically used in forensic samples.

   g. Partial profile: indicate whether the profile is a partial profile. The box should be marked "Yes", if the profile possesses additional data that could be used to exclude a match but was not or could not be entered for search. In addition, an allele call can be marked by selecting “Yes” in the “Partial Locus” column in STR Data Entry. This will automatically toggle the profile as a Partial Profile. If there is no additional DNA data that can assist in the exclusion or inclusion of a possible match, the box should be marked "No".
h. **Enter DNA profile:** The STR Data Entry application requires that the DNA data be entered twice to reduce data entry errors. It is acceptable for the same CODIS User to enter both sets. The STR Data Entry application will indicate if there is a mismatch between the duplicate data. If both are correct, the data set will be automatically repeated in a third column. CODIS will also prompt the user of a rare allele entry to confirm the rare allele was entered on purpose and not as a typographical error.

3. **Format for entering DNA data:**
   a. Heterozygotes and mixtures (in ascending order) should be entered as: "p,q"
   b. Homozygotes: "p,p" or "p"
   c. In the event of a single allele call, where “p,___” then toggle the option of “Partial locus” to “Yes” per qualifying loci.
   d. Alleles below or above the allelic ladder are entered as < (lowest allele) or > (highest allele), respectively.
   e. Single source profiles can be entered exactly as profiled.
   f. Mixtures can be entered in one of several ways to use the search capabilities of the CODIS software. The goal is to return significant candidate matches without incurring a large number of candidate matches.

4. **Examples of entering Forensic Mixture data into CODIS:**
   a. **Scenario 1:** An apparent 2 component mixture where the major/minor components can be defined:
      
      | Alleles | Peak height |
      |---------|-------------|
      | 14, 16  | 2000        |
      | 14, 17  | 1500        |
      | 17      | 500         |
      
      b. **Major profile:**
      
      | Data entry |
      |-------------|
      | 14, 16      |
      | 14, 16      |
      
      c. **Minor profile:**
      
      | Data entry |
      |-------------|
      | 14, 17      |
      | 14, 17      |

5. **The major and minor component profiles can be entered as separate single source profiles. In scenario 1, a clear major and clear minor profile can be discerned from each of the loci in the mixture, the profile may be entered under the Forensic Unknown/Partial or CA Forensic Partial categories.**
   a. **Scenario 2:** An apparent 2-person mixture with no clear major/minor contributors (e.g. the victim's profile from a sexual assault swab) where mixture interpretation can be a selected genotype call:
      
      | Alleles | Peak height |
      |---------|-------------|
      | 14      | 1600        |
      | 16      | 1300        |
      | 17      | 1200        |
      
      b. Victim's type: 14,16
      c. CODIS Data Entry (variation A): Use CODIS's ability to define one **obligate** allele using the (+) notation to indicate the profile must have 17 allele to return a match:
      
      | Data entry |
      |-------------|
      | 14,16,17+   |
      
      d. Discussion: CODIS matches to a homozygous "17" will return as a (High) match, matches to a 14, 17 or to a 16, 17 will return as (Moderate) matches. High or Moderate match means there is high or moderate stringency to the match. No match will be returned to a 14,16, a 14, or 16.
      e. CODIS Data Entry (variation B): Use only the foreign allele (17) as a search criterion. In STR Entry, toggle the “Partial Profile” column as “Yes” to indicate an allele call. A “{P}” will appear in the Specimen Detail Report if the locus is marked as an allele call.
      
      | Data entry |
      |-------------|
      | 17 {P}      |
      
      f. CODIS will return matches to 17 (as High), and to any heterozygote or mixture profile that contains 17 (as moderate.)
      
      g. **Scenario 3:** A complex mixture. These mixtures create the most havoc due to the potential for high numbers of candidate matches. To qualify per level of CODIS search, the profile must satisfy the minimum MME. The Match Estimator module in CODIS or another approved match estimator can be used to determine entry into CODIS. If possible, include selected genotypes in the interpretation to help eliminate potential matches.
h. In scenario 2, both variation A and B, and scenario 3, the profiles are required to be entered under the Forensic Mixture or CA Mixture category.

6. Save Data Entry: When all the data entry fields have been filled in correctly, the specimen can be added to the local CODIS database by selecting "ADD/Save". The specimen becomes a record in the Specimen Manager application.

7. Verify Specimen Information Entered: To verify that the data entered into CODIS is what was technically reviewed and intended to be entered, the CODIS user will document that they verified the data entered:
   a. Print a copy of the LDIS Specimen Detail Report. The report captures the specimen information entered into STR Data Entry.
   b. Compare the PCR Loci and allele values in the Specimen Detail Report against the copy of the Summary Data sheet (generated and technically reviewed as part of the DNA case file).
   c. Once verified the analyst will initial and date the Specimen Detail Report and the copy of the Summary Data sheet.
   d. The copy of the Summary Data Sheet is retained by the CODIS Administrator as a means of documenting uploads and verification of the data entered. The Specimen Detail Report is filed with the case file.

III. Search Procedure prior to Upload

A. Prior to an upload to SDIS, any newly entered or updated specimen(s) is autosearched against the indexes maintained in the local CODIS database by the CODIS Administrator or Alternate. This is to check the local database for any potential case-to-case hits and for quality control measures. The search can be conducted one of three ways:
   1. using the Searcher link in Specimen Manager,
   2. using the Searcher module, or
   3. using the Autosearcher module. For other types of searches, see Search Requirements below.

B. CODIS Administrator/Alternate will check for newly entered specimens that are awaiting upload:
   1. Select the Specimen Manager module. From list of saved search configurations, select "Check for upload". A list of any new specimens that are marked for upload will be listed. Note: any previously marked specimens that have been modified will not be listed such as when a specimen's source ID had been modified.
   2. Open each entry individually and verify the data entry fields for appropriateness. The casework analyst may be consulted for this task.
   3. If the STR entry is correct, the verifier will date and initial the copy of the Summary Data sheet. The CODIS Administrator/Alternate will search the newly entered specimen(s) with one of the following search applications: Searcher or Autosearcher.

C. Searcher:
   1. Select Specimen Manager module.
   2. In the Specimen Manager window, right click on a Specimen record. From the Pop-up window, select Search Profile. Searcher module will launch and the selected specimen record data are reflected in the Target Profile window.
   3. Edit the search parameters accordingly and Perform Search. Searcher returns candidate matches in the active window. Candidate matches appear in the Candidate Match window. (Note: searches conducted via the linked Searcher application through Specimen Manager must be manually saved to the Match Manager.) If a candidate match to a specimen is obtained, it should be manually saved to Match Manager (File>Save>To Match Manager).

D. Autosearcher: AutoSearcher at LDIS is an on-demand search of specimens within the database on a periodic basis. This search can be configured to test all specimens, or just previously unsearched profiles.
   1. Open the AutoSearcher module. From list of search configurations, select Monthly STR Search.
   2. Select the Perform Search button in the toolbar. AutoSearcher will return a list stating the number of matches added to Match Manager. Candidate matches are automatically saved to Match Manager. To view the Autosearch Report, open the Message Center module and select the latest Autosearch Report.

IV. Procedure for Uploading Specimens to SDIS

A. Prior to Upload
   The CODIS Administrator/Alternate will verify the following:
   1. The profile has undergone a technical review. (See BIO.3.CODIS.06 for technical review of vendor lab generated profiles).
2. The STR Data Entry fields (Specimen name, category, source ID, partial profile, etc.) have been filled in. The DNA analyst is responsible for the accuracy of the data entered.
3. The Moderate Match Estimation (MME) has been calculated to determine category of the specimen for upload level.
4. The specimen has been searched against the Local CODIS database.
5. The laboratory has the appropriate written request and documentations for uploading a Legal category profile. See below.

B. At this point in the process, the DNA profile entered into CODIS has been technically reviewed and searched against the Local CODIS database. By default, all forensic type specimens added to Specimen Manager are "marked" for upload. See NDIS Operational Procedures for specimens allowed to be marked for upload. The specimen must be manually unmarked if upload of the specimen is unwanted.

C. To unmark a specimen for upload:
   1. Select the Specimen Manager module and click on the specimen record to highlight the record.
   2. Right click on the specimen and select "Unmark for upload" from the pop-up list or toolbar.
   3. Verify that the sample has no date associated with the "Marked Date" and "Marked by" column headings.

D. Upload Procedure:
   Reminder: The laboratory shall not upload DNA profiles to NDIS in the event the CODIS Administrator position becomes unoccupied, until a new casework CODIS Administrator is appointed.

   E. The procedure for performing an upload is also explained in the FBI's CODIS Training Manual. There are two types of uploads (full and incremental) that a CODIS Administrator or Alternate may perform.
      1. Incremental: transmits all data that is new, modified, or deleted since the last time an upload was performed, if the data has been marked for upload.
      2. Full: transmits all data in the local database that has been marked for upload.
      3. To complete the upload, select Generate Upload from the menu bar and select Send Upload. Full uploads can be conducted on a periodic basis (approximately two times per year).
      4. Check upload reconciliation report for the associated upload: Once a profile is uploaded, received, and processed at the State, a reconciliation report is generated that verifies that the upper level CODIS system has received the upload. If the profile has been subsequently uploaded to NDIS, a NDIS reconciliation report will be issued. The reconciliation reports are sent electronically through Message Center on the CODIS computer. The CODIS Administrator and Alternate are responsible for reviewing the reconciliation report and checking for negative reconciliation codes associated with the upload.
         a. Open the Message Center module and select the Upload Reports tab. Unopened or unprocessed recon reports appear in red and with a star in the left hand column.
         b. Open unprocessed Recon Reports in the order of upload number, SDIS reports first. It is vital that the reconciliations be opened in the order of upload number to allow correct updates of the Specimen Manager records.
         c. Double click on the Upload Report to update audit trails.
         d. Export a PDF of the report to a designated folder on the workstation.

V. Search Requirements
   A. When data is uploaded, any new or modified data is "marked for upload" and flags the specimen as not searched. A profile entered into the local CODIS database is autosearched against other profiles in the database prior to upload to the State level. Previously unsearched profiles that have been uploaded to the State and National level are autosearched against the profiles in their respective databases on a scheduled basis, as determined by the State Administrator and NDIS Custodian.

   B. AUTOSEARCHES: The requirement for an autosearch is dependent on the index and level at which the profile will be searched. For example, in order for a specimen in the forensic index to be autosearched at NDIS, the specimen must have a minimum of 8 of the original core CODIS loci (See below for definition of original core loci) and satisfy the minimum NDIS MME. This differs from an autosearch conducted at the State level which requires a minimum of any 7 loci to search, however, has to have the minimum MME which is calculated off of the 13 original core loci plus D2 and D19. Refer to the NDIS Operational Procedures for a complete listing of required search parameters for indexes.

   C. Below is the number of loci required for an autosearch of the indexes applicable to the Office of the Sheriff's Laboratory. (Note: MME thresholds must be met to be entered in CODIS.)

<table>

**D. Keyboard Search:**

1. Profiles that do not meet the minimum number of loci/MME to be searched at SDIS and or NDIS may be searched via a keyboard search. A keyboard search compares the target DNA profile to other DNA profiles in the database without resulting in the target profile being uploaded or permanently included in the database. A keyboard search can be conducted at the State or National level. The request form can be found in the NDIS Operational Procedures. The DNA profile, where the profile was developed, and associated crime must be included with the keyboard request form.

   a. A Keyboard Search at SDIS: A keyboard search of the State database requires a written request be faxed or emailed to the State CODIS Administrator.

   b. A Keyboard Search at NDIS: If after a search of the State level database yields no matches, a request to search the NDIS database may be forwarded to the NDIS Custodian by the State CODIS Administrator. NDIS requires a minimum of 7 loci for searching. Refer to the NDIS Operational Procedures for the appropriate forms and cover letter required for the request. A communication in the form of a letter or e-mail, confirming the search was performed, shall be returned to the State CODIS Administrator or agency.

2. A match estimation, the number of potential hits estimated based on the DNA profile, must be performed prior to submitting the search request. Generally, one estimated match in the size of the database is accepted.

**E. Batch Target File Search:**

1. The **Searcher** module allows target profiles (either a singular profile or multiple profiles in a file) to be placed into a "Batch Target File" to be searched against the local CODIS database without the profiles being permanently entered into the local CODIS database. In other words, the profile(s) will not be stored in "Specimen Manager". Conducting a batch target file search is voluntary and may occur at the request of an external laboratory or initiated by the Office of the Sheriff's Laboratory.

   a. The location and procedure for a batch target file search is in the NDIS Operational Procedures:
      i. Navigate to the CODIS website homepage and locate “DNA Search Requests”.
      ii. Click on the following link “STR Target File” to download the batch target file.

**F. Legally Obtained Suspect Known Search:**

1. DNA profiles developed for reference purposes such as from a victim or suspect, other than from staff members for QC purposes, are not maintained in the LDIS database for searching or uploaded to the State. California Penal Code section 297(c)(1) authorizes a known sample legally obtained from a person who is identified by a law enforcement agency as a suspect in an ongoing criminal investigation to be placed in the California offender DNA database. Such a sample shall be known as a Legally Obtained Suspect Known (LOSK) sample. It is a special type of Legally Obtained Sample because of the two-year time limit for its retention in CODIS. The DNA record generated from a LOSK sample will be assigned to the Legal DNA record category and the Legal DNA index at LDIS, SDIS and NDIS. The LOSK sample is an evidentiary reference sample with a sufficient chain of custody. It will have been received and processed by the DNA casework laboratory providing service to the investigating agency. To qualify for upload to SDIS the LOSK sample must be documented by the submitting law enforcement agency with the following data:

   a. **Eligibility Requirements:**
      i. Subject’s identification: name, DOB, and means of identification (SID or CII number, Driver’s License, ID Card, etc);
      ii. Affirmation of the subject’s status as a suspect;
      iii. Investigator’s name, rank, ID number, agency and case file number;
      iv. Type of crime and county of jurisdiction.
      v. A completed CAL-DNA LOSK form with the requested information. (Refer to the SDIS procedures under Serology/CODIS Adm/CODIS Adm docs for the form).
vi. Expungement of the DNA profile when the two-years limit has been reached. If the subject is still part of an ongoing investigation, the profile can be renewed for another two years with a new LOSK form.

G. Interpol Search:

1. Refer to the CODIS website for the requirements of an Interpol search.

VI. Familial Search and "Partial Matches"

A. The California Department of Justice has authorized searching of the State database for an individual(s) who may be a close relative to the true source of the forensic specimen. Refer to the CA Department of Justice's published "Information Bulletin, no 2008-BFS-01" which describes the policy for familial searches.

1. Familial searching is based on the principal that first-order relatives, (siblings, parents) and to a lesser extent (aunt, uncles, cousins) share genetic features more so than does an unrelated individual. Thus, this type of search may be used as a tool for developing an investigative lead. A "partial match" may occur as a result of a routine autosearch or as a result of a special search request.

2. In the event of a "partial match" obtained through a routine search of the CA CODIS database, the following conditions must be met before the DOJ releases the offender's name:
   a. The target profile is a single source profile.
   b. The offender's profile shares at least 15 alleles throughout the profile.
   c. The case is unsolved and all investigative leads have been exhausted.
   d. A commitment is made by the agency and prosecutor to further investigate the case, if the name of the potentially related offender is released.
   e. A kinship analysis to indicate the strength of the association needs to be conducted.
   f. Y-STR analysis is completed by the submitting agency and is concordant with the Offender's Y-STR profile obtained by CA DOJ.
   g. A DOJ committee reviews the case and discusses the case with the law enforcement agency, the prosecutor's office, and the local laboratory. After review, the offender's name may be released.
   h. If a consensus is not reached, the decision to release the offender's name will be made by the Attorney General or his designee.

3. In the event that a law enforcement agency has an unsolved case that has critical public safety implications, the agency may request a familial search of the database for any offender(s) who may be related to the perpetrator. This request should be on agency letterhead. The name of the offender may be released to the investigating agency if all of the following conditions are met:
   a. A written request is sent to the State of California's Chief of the Bureau of Forensic Services (1102 Q Street, 6th Floor, Sacramento, CA 95811) describing the case and attesting that all other investigative leads have been exhausted, and that the investigating agency and the prosecutor's office are committed to further investigate the case if the name of the offender is eventually released.
   b. The evidence profile must be a single source profile.
   c. A Y-STR profile of the evidence has been completed by the submitting agency prior to the search.
   d. The search conducted by DOJ must result in a manageable number of candidates.
   e. The candidate matches will be prioritized by DOJ using statistical calculations for relatedness.
   f. Based on the prioritization, DOJ will conduct Y-STR typing on the offender sample(s).
   g. If the Y-STR profiles of the evidence and offender match, steps as described in section 2 above will be followed.

4. In the event of a partial match through an NDIS search, please refer to Appendix G of the NDIS Operational Procedures. Below is a copy of the NDIS partial match plan:

For purposes of this Plan, a “partial match” is a moderate stringency candidate match between two single source profiles having at each locus at least one allele in common indicating that a potential familial relationship may exist between the offender and the putative perpetrator (casework) profiles.

The FBI CODIS Unit is aware that there may be certain circumstances when NDIS participating laboratories encounter a candidate match that could be classified as a "partial match." For those candidate matches occurring at NDIS, the FBI has developed procedures with accompanying guidance to allow for the disclosure of personally identifying information by NDIS participating laboratories in appropriate cases.
The FBI is implementing this Plan to provide guidance to Casework Laboratories to pursue partial matches identified at NDIS in accordance with applicable State law and policies. This guidance will also assist the Offender Laboratory to determine whether to disclose information in accordance with applicable State law and policies to the Casework Laboratory requesting identifying information. Forensic Partial and Forensic Mixture profiles shall not be considered for purposes of determining a partial match.

**Casework Laboratory**

a. A Casework Laboratory involved in a partial match, after documented consultation with its agency's legal representative and the relevant prosecutor, may send a written request for the release of the personally identifying information of the offender involved in the partial match to the Offender Laboratory.

b. The Casework Laboratory shall direct a written request for the release of personally identifying information of the offender involved in the partial match, on the agency letterhead, to the Offender Laboratory and shall include the documented concurrence of the prosecutor. The Casework Laboratory shall provide the NDIS Custodian with a copy of the correspondence to the Offender Laboratory.

c. The casework profile must be a single source forensic unknown profile with a minimum of 15 Loci (original 13 CODIS core plus D2 and D19).

d. The written request by the Casework Laboratory shall include the statistical analysis used to conclude that there may be a potential familial relationship between the profiles identified by the Casework Laboratory and the Offender Laboratory.

e. Individual Expected Match Ratios (EMR) and Expected Kinship Ratios (EKR) shall be calculated according to "SWGDAM recommendations to the FBI Director in the “Interim Plan for the Release of Information in the Event of a ‘Partial Match’ at NDIS.” **The Casework Laboratory shall not submit a request to the Offender Laboratory that does not satisfy the EKR and EMR thresholds recommended by SWGDAM.**

f. The Casework Laboratory shall notify the NDIS Custodian in writing of the outcome of any further investigation and the final resolution of any resulting prosecution in the criminal case no later than 30 calendar days from the Casework Laboratory's notification by the prosecutor, other law enforcement entity or other reliable source of that outcome and resolution. The NDIS Custodian should be notified as to whether the criminal case was solved using the partial match information.

**Databank Laboratory**

1. The Offender Laboratory shall be responsible for determining whether the release of the offender's personally identifying information is prohibited by its applicable State law or policies.

2. The Offender Laboratory may request the Casework Laboratory perform additional DNA analysis (such as Y-STR and mtDNA), if appropriate to provide additional genetic data in common between the partial match offender and the putative perpetrator.

3. If the Offender Laboratory determines that the release of the offender's identity is permitted by its applicable State law or policies, the Offender Laboratory shall provide written notification of that determination and the offender's identity, on agency letterhead, to the Casework Laboratory. The Offender Laboratory shall provide the NDIS Custodian with a copy of the correspondence to the Casework Laboratory with the offender's personally identifying information redacted.

4. If the Offender Laboratory determines that the release of the offender's identification is not permitted by its applicable State law or policies, the Offender Laboratory shall provide written notification of that determination, on agency letterhead, to the Casework Laboratory. The Offender Laboratory shall provide the NDIS Custodian with a copy of the correspondence to the Casework Laboratory.

5. The determination of the Offender Laboratory having responsibility for the offender information shall be final.

5. See CODIS Manual sections: Disposition of Candidate Matches and Reporting and Disclosure of Matches for disposition and reporting of matches that have occurred as a result of a search.

END OF DOCUMENT
I. INTRODUCTION
   A. A "Match" occurs between a "Target" DNA profile and "Candidate" DNA profile based on the search parameters. Matches and hits are not interchangeable terms or events. A match simply signifies an association has been made between the DNA profiles. A "Hit" is a match that provides value to an investigation. Refer to the NDIS Operational Procedures for further differentiation and for the "Hit Counting" rules.

   B. Match + Investigation Aided = Hit

   C. The purpose of this document is to illustrate the proper disposition of matches, laboratory procedure for dispositions, and the CODIS Administrator / Alternate's responsibilities regarding dispositions.

II. DISPOSITION OF CANDIDATE MATCHES
   A. Matches in CODIS are processed differently depending on level and search type. A match occurring as a result of a Local CODIS search (via Searcher or Autosearcher) is populated automatically in Match Manager. (See section: Data Entry, Uploads, and Searches for more information.) CODIS automatically sends results of an autosearch to all laboratories involved conducted by SDIS or NDIS. These matches are sent via the Message Center module and will be processed by the involved laboratories. The results will be displayed per autosearch configuration and matches will be added to Match Manager when the message has been executed.

   1. Definitions:
      a. Message Center: A CODIS module used to communicate between CODIS labs.
      b. Match Manager: A CODIS module used as a storage center for all candidate matches.

   2. Types of Dispositions:
      a. Candidate Match: A possible match between two or more DNA profiles as a result of a search. This is the default disposition and serves as the interim disposition until the match record is opened. Once the record has been opened for viewing, the disposition automatically is updated to "Pending". See definition below.
      b. Pending: This is an interim disposition that indicates the match record has been viewed and is a temporary disposition only until an appropriate final disposition is applied. See other types of dispositions below.
      c. No Match: A disposition that updates an interim disposition (Candidate, Pending, or Waiting for More Loci Match) to reflect that the target DNA profile and the candidate DNA profile do not match. This disposition requires no further work. This is a final disposition.
      d. Conviction Match: A disposition of Conviction Match is when a match has occurred between a sourced ID'd forensic DNA profile and an Offender/Arrestee's profile. Since this match does not provide additional investigative information, no further work is required. Prior to dispositioning this match however, an inquiry must be made to the Offender Laboratory to confirm that the Offender is in fact the same named suspect already associated to the forensic unknown profile. See match procedure below.
      e. Benchwork Match: A disposition where CODIS has identified a match, however, the laboratory was already aware of the link between the cases or profiles before using CODIS. In other words, a CODIS search did not assist in providing a link between the cases. Classically, these are matches where an analyst recognizes that a profile from one case matches another. This would include a match between a Legally Obtained Suspect Known sample and a forensic unknown profile where the suspect was known previously to be associated with that case.
      f. Forensic Hit: This is a match between a DNA profile from a source unknown forensic specimen to another source unknown forensic specimen. The match is considered a forensic hit because it has assisted the investigations and the hit provides the investigators the link between the cases. This type of match provides useful investigative information and is therefore termed a "hit."
g. **Legal Hit:** A match between a Legally Obtained Suspect Known profile and a forensic specimen from an unsolved case where the suspect was previously unassociated with that case.

h. **Offender Hit/Arrestee Hit:** This disposition is for a match between an offender/arrestee's DNA profile and a source unknown forensic profile in an unsolved case. This is considered an Offender Hit when an investigator is unaware of the offender's involvement, had insufficient evidence to establish probable cause, or had not obtained a reference standard prior for comparison purposes. The match aids the investigation and provides useful investigative information, therefore it is termed a "hit."

   Note: In the event that the Offender/Arrestee Hit is discovered to match an elimination sample (consenting partner, victim, etc.), the forensic profile will be subsequently removed from the database and a comment explaining the match (e.g., match to consenting partner) can be provided in the match disposition comments field. See expungement procedure in section: Acceptance Standards, Eligibility, and Expungement.

i. **Duplicate:** This disposition is for a match that has occurred between a forensic specimen to more than one offender/Arrestee specimens with the same profile during the same search. The offender has been sampled more than once resulting in multiple records for the same individual. One of the matched pair records is dispositioned as an Offender Hit, and the second is dispositioned as a Duplicate. This applies to Conviction Matches to multiple offender specimen matches on the same search.

j. **Investigative Information:** At NDIS level - a disposition for a match where two or more solved cases have been linked through their DNA profiles. The match record does not provide investigative information in the identity of the suspect or aids either law enforcement agency's case. However, since there has been a positive association between the two cases, a notification must be written to notify the law enforcement agencies of the association. See reporting requirements section: Reporting and Disclosure of Matches. At LDIS level – a disposition for case-to-case matches of profiles that exist at SDIS. The subsequent SDIS search will produce the same candidate match where it will be either marked as Forensic Hit or State Defined #1 depending on source ID.

k. **State Defined #1:** This is used to mark case-to-case matches in SDIS when at least one of the profiles has the source ID known. This is used to update the CHOP database and notify those California Law Enforcement Agencies who have CHOP access.

l. **State Defined #2 and 3:** Situations for these dispositions have not been defined and is not in use.

m. **User Defined #1, 2 and 3:** Situations for these dispositions have not been defined and is not in use.

III. MATCH DISPOSITION PROCEDURE

   **A.** Match Manager is the CODIS module where the matches are stored. Matches resulting from a search of the Local CODIS database will appear in Match Manager. Results of an autosearch conducted at any level are sent to the Message Center module and results from each search will be contained in a Match Message.

   1. SDIS and NDIS Match Messages have to be manually executed to see the results of a search. This will show candidate matches and add them to Match Manager or indicate no matches resulted from the search.

   2. Double click on a single match record to access Match Details. The Match Details provides a means of viewing details of the match: The DNA profiles of the Target and Candidate specimens, the specimen names, the stringency of the match (High, Medium, and Low), search configuration, match audit trail, and dispositions.

   3. The result of opening a match record automatically (by default) modifies the disposition status from "Candidate Match" to "Pending." "Pending" is an interim status and must be updated in a timely manner (best effort within 30 business days) to an appropriate disposition.

   a. For single source profile matches where the target and candidate DNA profiles show concordant results at all loci, the profiles can be declared a match and the appropriate final disposition can be applied. See above for disposition options.

   b. For matches with less than high stringency (such as partial profiles and mixtures), evaluation of the match may require referencing the original case file notes to assist in the proper disposition of the match. See below for additional reviewer qualification requirements for dispositioning matches (NDIS Operational Procedures):

      i. A match occurring at all loci at high stringency may be reviewed and evaluated by an individual who is currently or was previously a qualified DNA analyst.

      ii. A match at any loci at less than high stringency shall be reviewed and evaluated by a DNA casework analyst who currently or was previously qualified in the technology (such as RFLP, STR's, Y-STR) being reviewed.
4. Disposition the Match. See above for appropriate disposition options.

B. If dispositioned Offender/Arrestee/Legal Hit:

1. A request must be made to the Offender Laboratory for the Offender's identifying information. Note: If the match is to a CA State Offender, the CAL DOJ Databank Laboratory will automatically initiate process confirm the offender sample once disposition is updated to Offender or Arrestee hit. The Offender Hit information will come to the Laboratory through the CODIS Hit Outcome Project (CHOP) program located through the RISSNET website.

2. If the match is to an Offender specimen from out of the state, a request for the identifying information must be made to the Offender Laboratory. An example request form can be found in the NDIS Operational Procedures. The Offender's information may be sent electronically through the LEO (Law Enforcement Online) program.

3. When the Offender's identifying information has been made known, the source ID field needs to be changed from 'NO" to "YES". As a result of this modification in the record, the profile will automatically be marked for upload to update the profile the upper level CODIS databases. No identifying information or criminal history records about an Offender (i.e. DOB, Name, CII/SID #) may be added to the record.

C. If dispositioned Forensic Hit or State Defined #1:

1. Contact the casework laboratory to facilitate an exchange of case file/investigative information. A request form (see NDIS Operational Procedures) can be used to initiate an exchange of case information with the candidate laboratory that will be needed for the associated law enforcement agencies. If the match occurred in SDIS, CHOP is the preferred platform for information exchange.

2. The exchange of information may be informally exchanged such as through the phone. This type of exchange requires documentation of the contact and content of the conversation.

3. A match may occur where the forensic unknown case is solved and the suspect's name is provided. Once the suspect's name is provided, the forensic profile will be changed from "No" to "Yes."

D. If dispositioned Conviction Match:

1. Prior to the disposition of these matches, the CODIS Administrator or Alternate will verify with the Offender Laboratory that the match is from the same (known) individual. This verification will be documented and will be maintained with the case file.

E. If dispositioned a Benchwork Match:

1. The definition of this disposition implies the laboratory was aware of an association between the forensic unknown profiles or to a Legal profile prior to searching in CODIS. However, if not already done so, the law enforcement agencies associated with the matches should be informed of the match and the exchange of case information should be provided to the law enforcement agencies, documented and maintained in the case files.

F. Keyboard Search:

1. The match(s) resulting from an external keyboard search will be transmitted to Match Messages through the Message Center Module. Any matches resulting from an internal keyboard search will be populated in Match Manager only when manually saved. All matches need to be dispositioned appropriately. Any match where a positive association has been made, follow-up contact will be made with the involved laboratory(s).

G. Batch Target File:

1. The results of a batch target file search will be in Match Messages. In the event of a match, the Laboratory who generated the target profile may need to be contacted to assist in the disposition and follow-up of the match. The match may be dispositioned as pending until further resolution of the match has been conducted. Upon resolution, a final disposition will be added.

2. Refer to section: Reporting and Disclosure of Matches for follow-up reporting requirements for matches dispositioned as Matches and Hits.

IV. CODIS ADMINISTRATOR/ALTERNATE'S RESPONSIBILITIES

A. Review and evaluate the match to determine if further information is needed to disposition the match or to assign a DNA analyst to further review the data to assist in the disposition of the match.

B. Ensure that a laboratory request is generated, when a follow up laboratory report is required (see section on Reporting and Disclosure of Matches).

C. Ensure the source ID field is updated following an Offender/Arrestee/Legal Hit.

D. Ensure candidate matches are dispositioned appropriately (See details above).
E. Ensure no personal identifying information; including criminal history is contained in the DNA record stored in CODIS.

END OF DOCUMENT
I. Introduction

A. The laboratory is responsible for reporting to the law enforcement agency when positive associations (meaning when information of value is obtained from a search) have occurred, as well as, under other conditions. The purpose of this document is to describe when and what is required of a report when a match and or hit has occurred as a result of a CODIS search and what case file documentation is required.

B. Additionally, this document discusses the laboratory's policy and procedure on disclosure of DNA records, DNA databases, reports and case file notes.

II. Reporting Requirements

A. When to report CODIS Matches and Hits:

1. ANAB interpretation of ISO 17025 5.10.1:
   a. Anytime a forensic sample profile is entered into CODIS under the condition that it will be repeatedly searched, a report must be generated (which may be a simplified notification) that informs the law enforcement agency that the profile was or will be entered into CODIS.
      i. DNA reports generated in the laboratory are verified to contain this information as part of the technical review process
   
   b. Anytime a positive association is made as a result of a CODIS search, a report or follow-up report must be generated. The report may be a simplified notification (i.e. Hit Notification letter or an email transmission) as long as the notification is written and a record of the notification is retained by the laboratory.
      i. The laboratory generates a laboratory report for the associated law enforcement agency(s) in the event that there has been a positive association between 1) a case-to-case hit (solved or unsolved), 2) an unsolved case-to-offender/arrestee hit and 3) an unsolved case-to-Suspect Known hit. See disposition definitions in section: Disposition of Candidate Matches.

   c. Anytime a search is conducted as a one-time search, a report must be generated stating the results of the search. A one-time search is defined as meaning the profile is not retained in the database and will not being automatically searched against the database on a routine basis. The report which may be in the form of a simplified notification, must clearly inform the law enforcement agency of the search.
      i. The laboratory generates a laboratory report for the associated law enforcement agency(s) anytime a keyboard search has been conducted. The report will contain the outcome of the search whether a negative or positive association has occurred.

B. When to generate a CODIS notification:

1. Offender/Arrestee Hits
2. Forensic Hits (including State Defined #1 and Investigative Information for NDIS case-to-case match where case is solved)
3. Legal Hits (Legally Obtained Suspect Known specimens)
4. Benchwork Matches
5. Keyboard Searches
6. Deleted Profiles

C. How to Report CODIS Matches and Hits

1. Laboratory Procedure
a. **Offender/Arrestee Hits:** Contact the Offender Laboratory to request that the Offender Lab begin the confirmation process for the identity of the Offender specimen. This will be performed by the CODIS Administrator/Alternate. NDIS requires the Offender Laboratory to verify the Offender profile prior to reporting the identifying information to the Target lab. The request for information can be documented using the CODIS DNA Match Data Request form (available on the CODIS website or see below). Note: The California Department of Justice automatically begins this process without a specific request.

OR

**Forensic Hits (including State Defined #1 for SDIS and Investigative Information for NDIS):** Contact the Candidate laboratory to exchange case information. The exchange of information can be requested using the CODIS DNA Match Data Request form available on the CODIS Website (see below) or via the CODIS Hit Outcome Project (CHOP).

b. Once the offender's ID is known and or the case information has been exchanged, the law enforcement agency will be notified to provide the investigator with the putative perpetrator's identifying information or case information. For California Offender/Arrestee Hits, information pertaining to hits will be released via CHOP, located on the RISS network. The LEO (Law Enforcement Online) network may be used for out-of-state and other lab-to-lab correspondence.

c. Generate a laboratory request and assign an analyst to prepare a CODIS Notification report detailing the hit. The report may be written by the analyst who generated the CODIS profile or the CODIS Administrator or Alt Administrator.

d. Modify the DNA record in CODIS: Change the Source ID from "No" to "Yes". **Reminder:** No identifying information about an Offender (i.e. DOB, Name, Criminal history information CII/SID #) may be placed in CODIS.

e. Prepare case file documentation. The **CODIS Match Documentation form** may be used to assist in documenting case file information. The case file documentation should consist of as many of the following, when possible:

   i. **Case File Documentation**

      1. A Match Inventory Report which lists all matches to the casework specimen at the time of the match
      2. The CODIS Match Detail Report(s) which typically includes the following information:
         1. The DNA profiles of the Target and Candidate specimens
         2. The level of the CODIS hit (LDIS, SDIS, NDIS)
         3. The type of match (Offender/Arrestee, Forensic)
         4. The match ID and specimen ID's
         5. The date the match occurred
         6. The candidate/target laboratory's ORIs
         7. The size of the database searched at the time of the match
      3. The report issued by the Offender Lab/or a laboratory's forensic hit documentation
      4. Records of correspondence and information received or provided to the investigating agencies.
      5. Copy of any keyboard fax request.
      6. Copy of the Legally Obtained Suspect Known sample form
      7. Contra Costa casework information:
         1. Laboratory case #
         2. Law Enforcement Agency
         3. Agency case number
         4. Contact person and number
         5. Type of case/Offense
         6. Date of Incident
7. Status of case: solved/unsolved

8. Candidate Offender or Casework Laboratory information:
   1. Laboratory ORI and specimen ID
   2. Laboratory contact name and number
   3. Casework Information:
      1. Law enforcement agency
      2. Case number
      3. Agency contact and number
      4. Type of case/Offense
      5. Status of case: solved/unsolved

f. Write Report (See below for report content) and issue to law enforcement agency

2. Report Content
   a. Anytime a DNA profile has been or will be entered into CODIS, the laboratory informs the law enforcement agency of the laboratory's intent to search their evidence profile(s) against the CODIS database(s). This notification, in practice, is a part of the original DNA report prepared by the DNA analyst who conducted the analysis and development of the profile.

   b. The profile may become a part of a routine search in the database, if eligible (see section: Acceptable Standards, Eligibility, and Expungement), or be a one-time search (keyboard search) of a database. When a positive association has been made due to any type of search, the agency must be notified. This notification, in practice, is in the form of a Laboratory report. A simple notification report (e-mail, Offender Lab Hit Notification letter), may satisfy the reporting requirement upon Laboratory policy approval.

   c. Elements of a report
      A laboratory report should address sufficient information for the agency to understand;
      i. what has taken place with their evidence profile,
      ii. what has occurred as a result of a search of CODIS, and
      iii. what, if any, follow-up investigative actions are required of the agency (i.e. obtaining offender reference sample, making contacts with other agencies). Due to the different types of hits, this information may vary. Laboratory Reports should include:
         1. Brief history/summary of the generation and source of the CODIS profile
         2. Specimen name and source
         3. Agency item number, where available
         4. Result of search

      Additionally for Offender Hit Report Information
      5. Offender identifying information
      6. A request for a reference sample from the named Offender to confirm the match

   d. A confirmation of the hit should occur. Confirmation of an offender hit means the target laboratory must conduct DNA analysis on the Offender's reference sample to do a direct comparison of the Offender's DNA profile to the forensic unknown profile. Note: Confirmation of Offender Hits to DNA profiles generated by a vendor laboratory will be conducted by the Vendor Laboratory who generated the profile or at the discretion of the Office of the Sheriff's Laboratory.

      Additionally for Forensic Hit Report Information:
      i. Law Enforcement Agency Information (i.e. agency case number, contact person, contact number)
      ii. Case type
      iii. Identifying Offender information, if available at this laboratory.

3. Disclosure of DNA Records
a. Disclosure of laboratory reports and case file notes:
   i. The release of laboratory reports and case files notes is addressed in the Division Manual:
      1. FSD.43: Issuance of Laboratory Reports
      2. FSD.45: Discovery requests for Records

b. Disclosure of DNA records and database information
   Definitions:
   i. Databases: a collection of multiple DNA records.
   ii. DNA Record: a database record that includes the DNA profile as well as data such as the Agency Identifier, specimen identifier, and DNA analyst associated with the profile (NDIS Operational Procedures/QAS definition).

c. The laboratory's DNA records are considered confidential. In the event that there is a request for the release of DNA records or database information (whether in CODIS or from an internal laboratory database), the laboratory will follow applicable state and federal law regarding access and disclosure of DNA records:
   i. The Federal DNA Identification Act of 1994 (as amended by the DNA Backlog Analysis Elimination Act of 2000; "DNA Act") provides that the National DNA Index System "shall include only information on DNA identification records and DNA analyses that are maintained by Federal, State, and local criminal justice agencies (or the Secretary of Defense in accordance with section 1565 of title 10, United States Code) pursuant to rules that allow disclosure of stored DNA samples and DNA analyses only--
      1. to criminal justice agencies for law enforcement identification purposes;
      2. in judicial proceedings, if otherwise admissible pursuant to applicable statutes or rules;
      3. for criminal defense purposes, to a charged defendant, who shall have access to samples and analyses performed in connection with the case in which such defendant is charged;
      or
      4. for other forensic purposes; for population statistics database, for identification research and protocol development purposes, if personally identifiable information is removed, or for quality control purposes." [42 U.S.C.§14132(b)(3)]
   ii. Federal DNA Advisory Board Resolution (Resolution on Review of Privacy Issues)
      The Board reviewed the access and disclosure provisions provided by the DNA Identification Act of 1994. The Board agreed with the FBI's interpretation of the access provisions and supports the current level of enforcement of such access and disclosure provisions. The Board made recommendations that State laws provide for confidentiality of DNA records/samples that comply with the Federal DNA Act. Of concern are those states that appear to have more permissive laws for access to their DNA data. Compliance with the Federal DNA Identification Act will be audited by the Department of Justice Office of Inspector General.
   iii. The California Penal Code 299.5 to 299.6 provides for the disclosure of DNA records at the State level and states in part:
      1. 299.5(f) DNA samples and DNA profiles and other forensic identification information shall be released only to law enforcement agencies, including, but not limited to, parole officers of the Department of Corrections, hearing officers of the parole authority, probation officers, the Attorney General's office, district attorneys' offices, and prosecuting city attorneys' offices, unless otherwise specifically authorized by this chapter. Dissemination of DNA specimens, samples, and DNA profiles and other forensic identification information to law enforcement agencies and district attorneys' offices outside this state shall be performed in conformity with the provisions of this chapter.
      2. 299.5(g) A defendant's DNA and other forensic identification information developed pursuant to this chapter shall be available to his or her defense counsel upon court order.
      3. 299.5(h) Except as provided in subdivision (g) and in order to protect the confidentiality and privacy of database and data bank information, DOJ and Local public DNA laboratories shall not otherwise be compelled in a criminal or civil proceeding to provide any DNA profile or forensic identification database or data bank information or its computer database program software or structures to any person or party seeking such records or information whether by subpoena or discovery, or other procedural device or inquiry.
4. **299.6(1)** The procedures used by the local public DNA laboratory for the handling of specimens and samples and the disclosure of results are the same as those established by the Department of Justice pursuant to Sections 297, 298, and 299.5.

1. According to ASCLD/LAB (ISO 17025): CODIS is considered an Individual Characteristics Database (ICD). Any evidence sample from which a DNA profile has been produced, as part of a criminal investigation (regardless of whether the profile is entered into CODIS), is considered and treated as evidence prior to and after the development of a DNA profile. See the Division Manual for procedures which address the submission, movement, security, handling, disposition and release of evidence through the laboratory.

d. The Laboratory will respond to requests for access to a DNA record, by the subject of that record, in accordance with State law, when that record has been generated by the laboratory.

i. A defendant may have access to DNA samples and his/her exemplar samples and the analyses performed in connection with his/her case. The defendant is not entitled access to all of the DNA records, samples, or the DNA analyses that is not associated with his/her case, under the provisions of the DNA Act.

ii. The level of documentation routinely contained within original DNA analysis report(s), case file notes and reports/notes associated with a "CODIS Match/Hit" report, predominantly will capture any and all DNA records relevant to a defendant's case and should satisfy a discovery request for disclosure of DNA records and databases records related to the defendants case. See case file documentation and report content above.

e. The Laboratory, if not the investigation agency, will not publicly disclose or make any public statements regarding information obtained from or included in CODIS and/or in NDIS that would directly or indirectly identify unapprehended suspects without the prior approval of the investigation agency.

f. **Reminders:**

   Information in the NDIS Operational Procedures is the property of the Federal Bureau of Investigation and may be distributed to federal, state, tribal, or local government law enforcement officials with a need-to-know, as determined by the FBI. Distribution without FBI authorization is prohibited. Precautions should be taken to ensure this information is stored and/or destroyed in a manner that precludes unauthorized access.

g. No personally identifiable information relating to the donor, such as name, date of birth, social security number, or criminal history record number, is included in a DNA record stored at NDIS.

END OF DOCUMENT
I. The goal of the Biological Screening training program is to provide a trainee the knowledge, skills, and ability to perform biological screening on casework samples.

A. Intent of the Training Program

1. To develop knowledge, skills, and abilities in the area of biological screening culminating in the ability to perform screening for blood, semen, and saliva on casework samples.

2. To develop the necessary skills required for performing biological screening, such as evidence handling, using proper equipment, analyzing samples, interpreting results, etc.

3. To develop the knowledge necessary to provide expert testimony in biological screening in court.

B. Overview of the Training Program

1. Training is required for a new biology screener or a current employee new to biological screening, prior to conducting casework. The training program for biological screening should take approximately 4 months to 1 year.

2. The training will be tailored to the employee's job duties and to the extent they will conduct casework.

3. Training may be abbreviated for an employee with previous training and prior casework experience. Records of the employee's prior training and experience will be reviewed by the Supervisor and will be maintained in the LIMS training module. A copy may also be maintained in the employee's training binder.

4. Training will be under the guidance of a Unit Supervisor or an experienced member of the Biology Unit.

5. Training will entail literature readings and hands-on practical exercises. Training is administered in a modular format and assessments are built into each module, which allows for the trainee to begin casework in any of the areas for which the trainee was trained and competency tested. Training may also be supplemented by external training, such as college coursework, workshops, or other formal training courses.

6. Separate training will given for DNA analysis, see BIO.4.TRAIN.02

C. Educational Requirements:

1. The roles of individuals in the Biology unit and the educational requirements for each role is documented in BIO.5.QAQC.05.

D. Expectations of the Trainee

1. The trainee is expected to keep a notebook/binder of information compiled during the training program, including practical exercises.

2. The trainee will document their progress on the Biological Screening Training Log, BIO.1.BIOF.04, to include the date each portion of the training was completed, the trainee's initials, and the date and initials of the trainer. The training records will be retained in LIMS and may also be maintained in the trainee's training binder.

3. Trainees are expected to communicate any concerns about their training to the training coordinator and/or Unit Supervisor.

E. Guidelines for Competency

1. To demonstrate the trainee's knowledge, skills, and abilities, the trainee will undergo a competency test to the extent they received training, prior to participating in casework. See BIO.5.QAQC.13 for Biology's procedures regarding competency testing. Criteria for successfully passing the competency test will be documented prior to the individual receiving the competency test. A record of the competency test will be tracked and maintained through LIMS.
2. The signature of the Unit Supervisor on the training log will signify approval of the training and successful completion of the competency test. Approval signifies authorization for the trainee to conduct casework using all the equipment, instrumentation and procedures to the extent they received training and were competency tested.

3. If the trainee is expected to issue laboratory reports and has met the report writing competency requirements, the trainee will also be considered to be authorized to issue reports and give opinions and interpretations in the areas(s) for which they received training and competency.

4. The examiner will enter into the proficiency test cycle within a year of the authorization to conduct casework.

F. Task 1. Laboratory Introduction

New employees undergo an orientation program prior to the commencement of training. The orientation covers a variety of topics, such as safety, ethics, and quality assurance. Refer to FSDF.01 for a list of topics covered under orientation. Related topics that are specific to Biology Unit operations and procedures are addressed in the below training plan:

1. Goal: To familiarize the trainee with the Biology Manual and the expectations of the training program.

2. Task:
   a. Review and discuss the Biology Training Manual and the training plan
   b. Review the Biology Screening Procedures Manual
   c. Introduction to the Quality Assurance/Quality Control Program
      i. Review the Biology Unit's QA/QC Manual
      ii. Review the Forensic Services Division Manual
      iii. Instruction/Discussion on Contamination Controls/Prevention.
   d. Review the FSD Safety Manual
      i. Bloodborne Pathogen Training
      ii. Chemical Hygiene Training
      iii. Chemical Waste Disposal Training
   e. Orientation to the laboratory facility and security features.
   f. Description of the organization and management
      i. Goals and Objectives
      ii. Code of Ethics
      iii. Chain of Command of the Forensic Services Division
      iv. Laboratory administrative policies
   g. Ethics and Bias as it relates to forensic biology

3. Assessment:
   a. This module will be completed by biological screening trainees and laboratory support personnel assigned to the biology unit.
   b. Evaluate and discuss with the trainee his/her understanding of laboratory and Biology Unit's Policies.
   c. Successful completion of each task will be documented on the Biology Training Log.
   d. Review of biology and division policies and procedures will be documented through Power DMS.

G. Task 2. Evidence/Sample Handling and Control

1. Goal: Develop an understanding of sample and/or evidence control in the forensic laboratory.

2. Tasks:
   a. Receive instruction on the following, as applicable:
      i. Sample and/or evidence collection, packaging, and storage
      ii. Chain of custody, receiving, and handling samples and/or evidence
      iii. Case acceptance policy/Case management
iv. Case workflow  
v. Consumption of samples and/or evidence  
vi. Distinction between evidence and work product  
vii. Laboratory documentation policy (paper and/or electronic)  

b. Review LIMS presentation (QAT.09) and LIMS DOS and DON'TS (QAT.09.01) in powerDMS.  

3. Assessment:  
a. Documentation of successful completion/assessment of each task shall be noted on the trainee's Training Log.  
b. Evaluate and discuss with the trainee his/her knowledge and understanding of laboratory and Biology Unit's Policies.  
c. A record and acknowledgement of the review of these policy and procedures is captured through Power DMS.  

H. Task 3. Fundamental Scientific Knowledge  
1. Goal: To ensure the trainee has or is provided the formal education and working knowledge of the fundamental scientific basis of forensic serology.  
2. Task/Reading Assignments: Review and be familiar with the following references:  
c. SWGDAM Guidelines for the Processing of Sexual Assault Evidence Kits in a Laboratory.  
3. Assessment:  
a. Evaluate and discuss with the trainee his/her knowledge and understanding of biological screening  
b. Completion of this task will be assessed by review of college transcripts and, if necessary, review of course descriptions or syllabi, and completion of the assigned reading.  

I. Task 4: Examinations for Blood  
1. Applied Scientific Reading Material The goal of this module is to provide practical hands-on instruction and applied knowledge to the trainee on blood screening procedures. Read the reference literature below and review the blood screening procedure, see BIO.1.BIO.03.  
a. Ortho-Tolidine/Presumptive Tests  
ii. Cox, M., "A Study of the Sensitivity and Specificity of Four Presumptive Tests for Blood  
iv. "Chemistry of Tests Used for the Identification of Blood", California Criminalistics Institute Basic Serology Course Notebook, Chap. II.  
b. HemaTrace Testing  

c. Safety
i. Read the SDS's for each of the presumptive blood testing reagents.

2. Hands on Testing

3. Ortho-Tolidine
a. Dried Blood Dilution Samples:
   i. Goal: Evaluate the sensitivity of the o-tolidine presumptive test, as well as the length of time to see a positive test result.
   ii. Task: Using liquid blood, prepare dried bloodstains on cloth swatches using neat, 1:10, 1:100, 1:500, 1:1000, 1:5000, and 1:10,000 dilutions of blood in water. Test each dried stain with o-tolidine, until no positive reaction occurs, using the transfer method (rubbing the stain) and the direct method (applying reagents directly to the stain).
      1. Record the visual color appearance of the dried samples.
      2. Record the length of time to see a reaction for each of the test results. Save swatches for the Hematrace exercises.

b. Fresh Blood Dilution Samples:
   i. Goal: Evaluate the sensitivity of the o-tolidine presumptive test, as well as the difference in sensitivity of the test with liquid blood compared to dried bloodstains.
   ii. Task: Transfer a portion of the liquid blood dilutions created above to a spot well plate and test the liquid dilutions directly with the o-tolidine presumptive test.
      1. Record the visual color appearance of the liquid samples.
      2. Record the length of time to see a reaction for each of the test results.

   c. Non-blood Samples:
      i. Goal: Evaluate the specificity of the o-tolidine presumptive test with non-biological samples. Record any false positive results and the visual color/appearance of the non-blood substance.
      ii. Task:
          1. Test o-tolidine on dried non-blood substances, such as ketchup, horseradish, tomato, 20% and undiluted bleach, chocolate, coffee, and rust using the transfer method.
             1. Observe and record any color development and the length of time, over several minutes.
          2. Repeat using fresh (non-dried) samples and using the direct method.
             1. Observe and record any color development and the length of time, over several minutes.
          3. Using a water moistened swab, rub a copper jacketed bullet and test using the transfer method and the direct method.
             1. Observe and record any color development and the length of time, over several minutes.
          4. Using a water moistened swab, rub a lead bullet and test using the transfer method and the direct method.
             1. Observe and record any color development and the length of time, over several minutes.

   d. Other Body Fluids:
      i. Goal: Evaluate the test for sensitivity of blood (occult blood) in other body fluids.
      ii. Task: Test o-tolidine using the transfer method and the direct method on the following body fluids. Record the length of time for a positive test result. Save swabs for the HemaTrace exercises.
          1. Oral swab
          2. Vaginal swab
          3. Rectal swab
4. Semen on a swab
5. Dried Urine (can use toilet paper as a "collection device")
6. Dried Feces (can use toilet paper as a "collection device")

e. Transfer Method vs. Direct:
   i. Goal: To consider any downstream testing, such as HemaTrace testing, DNA, that could be affected by
      the choice of using the transfer method vs. the direct method on limited bloodstains.
   ii. Task:
      1. Smear a small amount of blood on a piece of fabric (such as a cotton swatch) and on a non-absorbent
         surface. Both stains should be barely visible.
      2. Rub the stained area with a swab moistened with water, and separately rub the stain with the tip of a
         folded filter paper. Repeat on nearby unstained areas as a substrate control.
      3. Test the swab, filter paper, and the substrate controls using o-tolidine.
      4. Repeat using the direct method. What limitations occur with following this method?
      5. Record test results for future reference.

f. Stain Patterns and Photo Documentation:
   i. Goal: To evaluate and observe the visual appearance of deposited blood and bloodstain patterns caused by
      blood in motion by various events.
   ii. Task: Use appropriate personal protective equipment (gloves, full-face shield, disposable tyvek suit) and
      conduct inside a chemical fume hood. Prepare blood stains on various fabrics using assorted deposition
      techniques. These depositions should include direct transfers from several objects, transfers with swiping
      motion, wipes through pre-existing wet bloodstains, dripping blood from a disposable pipet, stains produced by
      dripping blood into a blood pool, and atomized blood stains (use compressed can of air to break apart a single
      hanging drop from a pipet tip.)
      1. Describe the overall appearance of each stain pattern, including size, shape, distribution, voids and any
         appearance of motion.
      2. Document the stains with photography using appropriate scales.

h. Washed Blood:
   i. Goal: Evaluate the affects of washing bloodstains on presumptive test results using both transfer and direct
      methods.
   ii. Task: If not already available, prepare washed bloodstains: Deposit diluted, such as 1:2, 1:10 and 1:50, and
      undiluted blood onto two sets of cloth swatches and allow to dry 1 to 2 days. Wash one set in cold water and
      the other in hot water and put through a dryer. Test the washed stains using o-tolidine. Conduct tests using the
      transfer method as well as the direct method using o-tolidine.
      1. Record the visual color appearance of the stains, as well as the test results for future reference. Save
         swatches for the HemaTrace exercises.

h. Aged Blood:
   i. Goal: Evaluate the affects of environmental conditions and aging on the ability to detect blood using a
      presumptive test.
   ii. Task: If not already available, prepare aged bloodstains: Deposit neat and diluted (1:2, 1:10, 1:50, 1:100,
      1:200, 1:500, 1:1000) onto two sets of cloth swatches. Allow one set to be exposed to hot temperatures and/or
      direct sunlight and the second at room temperature with no direct sunlight for approximately 1 month. Test the
      aged stains using o-tolidine. Conduct tests using the transfer method and the direct method. Record the visual
      appearance of the stains, as well as any difference in test results. Save swatches for the HemaTrace exercises.

4. Human Hemoglobin (HemaTrace testing)
      Evaluate whether there is a difference using the kit buffer compared to water. Evaluate how insolubility, due to
      washing and aging, can affect test results. Evaluate the presence of hemoglobin in other body fluids and
      specificity to other animals.
   b. Tasks:
i. Review the literature above and the procedure on the use of human hemoglobin test devices, BIO.1.BIO.03.

ii. Extract the dried blood stain dilutions prepared above using the test kit buffer. Test the dried stains, starting at the 1:10 dilution and continue until no positive reaction occurs. Record the dilution at which no reaction occurs. Record any color in the buffer extract at each dilution.

iii. For those diluted samples above that had a positive reaction, extract the same dried bloodstains using sterile distilled water. Record any color in the extract at each dilution. Record any difference between using the buffer and water.

iv. Test a few of the washed bloodstains using the test kit buffer. Record any color in the extracts. Record any reaction differences, if any, between the hot and cold washed stains. Record how this compares to the sensitivity of the o-tolidine results.

v. Test the aged bloodstains using the test kit buffer. Test the aged dilution stains until no positive reaction occurs. Note any color in the extracts. Note the dilution at which no reaction occurs. Record how this compares to the sensitivity of the o-tolidine test and to fresh stains.

vi. Extract one of the positive aged bloodstains and one of the negative aged bloodstains using the ammonia protocol. Was there an improvement in reaction? Record results.

vii. Conduct testing on the following materials; Oral, vaginal, rectal, semen, feces, and urine. Was there any reactivity with other fluids? Record results.

viii. Conduct specificity testing on commonly encountered animal bloods, such as dog, cat, chicken, fish, goat, and cow. Record results.

5. Infra-red Camera/Video Screening:

   a. **Goal:** Evaluate the affects of different colored and textured fabrics on the ability to detect bloodstains through an infra-red camera.

   b. **Task:** If not already available, place blood on various dark colored and textured fabrics and allow to dry. Review the procedure on Infra-red screening. BIO.1.BIO.02. View the fabrics under the infra-red, discuss, and document your findings.

6. Assessment:

   a. The trainee's understanding of the purpose of each test and its strengths and weakness will be evaluated through oral interview and review of the examiner's training note packet.

J. Task 5: Examinations for Semen

   1. **Applied Scientific Reading Materials:** The goal of this module is to provide practical hands-on instruction and applied knowledge to the trainee on semen screening procedures. Read the literature reference listed below and review the semen screening procedure, see BIO.1.BIO.04.

      a. **Acid Phosphatase Testing**

         viii. Dziack, Renata, "Providing Evidence Based Opinions on Time Since Intercourse (TSI) based on Body Fluid Testing,"

         ix. SERI AP Spot Test Internal Validation Study
b. Safety
   i. Read the SDS's for each of the presumptive semen testing reagents

c. P30
   i. Technical Information Sheet provided by manufacturer, Abacus Diagnostics. "OneStep ABAcard p30 Test for the Forensic Identification of Semen". 1999

d. Spermatozoa

e. Alternate Light Source

2. Presumptive Semen Test (Acid Phosphatase)
   a. Semen Dilution:
i. **Goal:** Evaluate the sensitivity of the AP spot tests.

ii. **Task:** Using liquid semen, prepare dried semen stains on cloth swatches using neat, 1:2, 1:10, 1:50, 1:100, 1:200, and 1:500 dilutions of semen in water. Test a portion of each dried stain using the AP spot test method using Fast Red RC Salt or Fast Blue BC Salt and SERI AP Spot test.

   1. Record the length of time for reaction and record observations.
   2. Save remaining cloth swatches for p30 and Sperm Identification exercise.

b. **Other Body Fluids:**

i. **Goal:** Evaluate the reaction that occurs with other body fluids.

ii. **Task:** Sample an approximate 1/4 to 1/3 portion of the following swabs and conduct acid phosphatase spot testing on the following samples. Record the color and time to reach a reaction and maximum color. Record observations and test results for future reference. Retain remaining swabs for p30 testing.

   1. Blank swab
   2. Swab with semen
   3. Vaginal swab
   4. Oral swab
   5. Anal swab
   6. A swab with a mixture of blood and semen
   7. Save a portion of the swabs (approximately 1/2) for p30 testing exercise.

c. **Washed Semen:**

i. **Goal:** Evaluate the affects of laundering on the ability to detect semen using the presumptive tests.

ii. **Task:** If not already available, prepare washed semen stains: Deposit diluted semen, such as 1:2 and 1:4 semen/water dilutions, and neat semen onto two sets of cloth swatches. Allow them to dry for 1 to 2 days. Prepare a control set that is not washed. Wash one set in cold water and the other in hot water and put through a dryer. Test the washed stains and control using an AP spot test. Record the visual appearance of the stains, as well as the length of time for a positive rxn and color of rxn. Retain remaining semen stains for the ALS and p30 testing exercises.

d. **Aged Semen:**

i. **Goal:** Evaluate the affects of aging on the ability to detect semen using the presumptive tests.

ii. **Task:** If not already available, prepare aged semen stains: Deposit neat and diluted semen, such as 1:2, 1:4, 1:8, 1:16, 1:32, 1:64, 1:128, 1:256 onto two sets of clean cloth swatches. Allow one set to be exposed to direct sunlight and a second control set to be stored at room temperature protected from sunlight for approximately 1 month. Test the stains in increments using an AP Spot test until no reaction is obtained. Test any aged semen stains that may have previously been created by the laboratory as well. Record the visual appearance of the stains, as well as the length of time for a reaction and the color development of the reaction. Save swatches for the ALS and p30 testing exercises.

e. **Degradation**

i. **Goal:** Evaluate the effects of storage conditions on AP activity.

ii. **Task:** Using neat, 1:2, 1:4, 1:10, and 1:50 dilutions of semen in water, deposit onto two sets of clean cotton swatches. Deposit a sufficient amount of material to be tested several times for AP spot, as well as for p30. Without allowing the stains to dry, place one set in the refrigerator, and the second set in an incubator at >37°C, in a sealed plastic bag. Test stains for AP activity and p30 at approximately 30 days. Record the visual appearance of the stains, as well as the length of time for a reaction and the color development of the reaction. Save p30 extracts (frozen if not testing immediately) for the Identification of Sperm exercises.

3. **ALS and AP Mapping:**

   a. **Goal:** Evaluate how different colors and textures affect the ability to locate a semen stain using an ALS. Compare these results with the AP Mapping technique.

   b. **Task:** If samples are not already made, using a 1:2 dilution of semen and water, and neat semen, apply to fabrics of different color, such as yellow, dark blue, purple, black and different types, such as cotton, permanent press, nylon, and other types and allow to air dry. Use an ALS to search for the stains and conduct AP Mapping. Use an
ALS to search for the aged and washed stains. Record your observations and compare the ALS differences between the stains.

4. **Alternate Light Source Screening**
   a. **Task:**
      i. Read and discuss the instrument procedure on [BIO.1.BIO.02](#).
      ii. Using the samples of semen applied to swatches of different types of fabric (cotton, jeans, polyester, velour, corduroy, etc) attempt to locate the stain on the fabric with a visual exam. Lightly feel the fabric and note stiffness in the area of the stain, if any.
      iii. Look at the fabric swatches using an alternate light source under different wavelengths of light and different colored goggles. Record your observations and findings.

5. **AP Mapping:**
   a. **Task:** Practice the AP Mapping technique using filter paper transfers on the above different fabrics using Fast Red RC Salt and Fast Blue BC Salt. Record the length of time for a positive rxn. Evaluate and compare the color development differences between the two dyes.

6. **P30** Read the reference literature listed above and review the procedures on p30 testing using p30 test devices, see [BIO.1.BIO.04](#).
   a. **Semen Dilutions:**
      i. **Goal:** Evaluate the sensitivity of the p30 test. Compare sensitivity of the p30 test to the AP spot presumptive test.
      ii. **Task:** Using the semen dilutions prepared above for AP Spot testing, test the sensitivity of the p30 test. Test the dried stains, starting at the 1:2 dilution and continue until you have reached a dilution where no positive reaction occurs. Record the dilution at which no reaction occurs. Note how this compares to the sensitivity of the presumptive test.
   b. **Other body Fluids:**
      i. **Goal:** Evaluate the presence of p30 in other body fluids.
      ii. **Task:** Conduct p30 test on other semen-free body fluid swabs, such as on oral, vaginal, and rectal swabs, and on dried urine and feces and dried breast milk (if available). Record all test results.
   c. **Post-Coital:**
      i. **Goal:** Evaluate the persistence of the p30 test.
      ii. **Task:** Conduct p30 on post-coital swabs collected at varying time intervals, such as every 4-8 hours up to 2 days. Test the time interval swabs until you have reach an interval where no positive reaction occurs. Record the interval at which no reaction occurs. Record all test results. (The ability to conduct this test is dependent on an available donor, thus is optional).
   d. **Washed Semen:**
      i. **Goal:** Evaluate how washing can affect test results. Compare the sensitivity of the p30 test to the AP spot presumptive test.
      ii. **Task:** Conduct p30 test on one set of washed semen stains and the control stains. Compare and record the test results.
   e. **Aged Semen:**
      i. **Goal:** Evaluate how insolubility, due to aging, and environmental conditions can affect test results. Compare sensitivity of the P30 test to the AP spot presumptive test.
      ii. **Task:** Conduct p30 test on one set of the aged semen stains and the control stains. Record any observance of insolubility of the stains. Compare the sensitivity of p30 to the AP spot test. Record all test results.
   f. **Degradation**
      i. **Goal:** Evaluate the effects of storage conditions on p30 activity. Compare these results to the results obtained for the AP spot presumptive test.
      ii. **Task:** Test stains for p30 activity at approximately 30 days. Record the visual appearance of the stains, as well as the length of time for a reaction and the color development of the reaction. Which semen component (AP or p30) persists longer? Retain extracts and prepare slides for the Identification of Sperm exercise.
7. **Identification of Spermatozoa** Read the reference literature listed above and review the procedures on stain and swab extraction, microscopic examination, and staining, see BIO.1.BIO.02 and BIO.1.BIO.09.

   a. **General Microscopy**

      i. Receive training on the following:

         1. Parts of a microscope
         2. Slide preparation
         3. Staining methods
         4. Bright field vs Phase Contrast

   b. **Semen Dilutions:**

      i. **Goal:** Compare the differences and evaluate the difficulties between identifying spermatozoa from neat semen and diluted semen.

      ii. **Task:** Extract the semen stains on cloth containing neat, 1:10, and 1:50 dilution of semen.

         1. Elute the material gently so as not to break the tails from the sperm cells.
         2. Prepare slides and stain with Christmas Tree stain.
         3. Examine the slides microscopically at 400X and 200X with bright field and phase contrast for the presence of intact spermatozoa.

   c. **Vaginal Swabs:**

      i. **Goal:** Compare the differences and evaluate the difficulties between identifying spermatozoa from neat semen and semen mixed with other body cavities.

      ii. **Task:** Using vaginal swabs spiked with semen or post-coital swabs, if available, extract swabs, with varying concentrations of semen.

         1. Prepare slides from the swab extracts and stain with Christmas Tree stain.
         2. Examine the slides microscopically at 400X and/or 200X with bright field and phase contrast.
         3. Differentiate between spermatozoa, white blood cells and yeast.

   d. **Washed Stains:**

      i. **Goal:** Evaluate the differences in washed stains compared to unwashed stains.

      ii. **Task:** Extract the semen stains from the diluted and neat semen stains from the washed cloth as well as from the unwashed set.

         1. Prepare slides from the extracts and stain with Christmas Tree stain.
         2. Examine the slides microscopically.
         3. Record number of sperm in each.

   e. **Degradation**

      i. **Goal:** Evaluate the presence and condition/morphology of the sperm following storage conditions.

      ii. **Task:** If not already prepared, extract the semen stains from the degraded stains prepared under the AP spot and p30 exercises above and prepare slides from the extracts.

         1. Stain with Christmas Tree stain and examine at 400X and/or 200X with bright field and phase contrast.
         2. Record the presence and condition of the sperm number.

   f. **Animal Spermatozoa:**

      i. **Goal:** Compare the differences between human and animal spermatozoa.

      ii. **Task:** Examine the collection of animal spermatozoa slides and compare the appearance of human sperm cells to those from other species (nineteen species in collection). Record observations and differences.

8. **Assessment:**

   a. The trainee's understanding of the purpose of each test and its strengths and weakness will be evaluated through oral interview and review of the examiner's training note packet.
K. Task 6: Examination of Vaginal Material

1. Applied Scientific Reading Materials:
   a. **Goal:** The goal of this module is to provide practical hands-on instruction and applied knowledge to the trainee on screening procedures used to evaluate vaginal material.
   
   b. **Task:** Read the literature references below and review the procedures on stain and swab extraction, microscopic examination, and staining, see BIO.1.BIO.02 and BIO.1.BIO.09.
      
      
      
      
      

   c. **Safety**
      
      i. Read the SDS's for each of the testing reagents.

2. Christmas Tree Stain:
   a. **Goal:** Evaluate vaginal material and be able to differentiate between vaginal cells, yeast, and bacteria. Observe and recognize features of the cellular material contained in vaginal material and the differential staining of the various vaginal cells.
   
   b. **Task:** Extract a vaginal swab (no semen) and prepare a slide from the extract.
      
      i. Stain the slide with Christmas Tree stain.
      
      ii. Examine the slide microscopically at 400X and 200X with bright field and phase contrast.

3. Slide Collection:
   a. **Goal:** Observe and differentiate the various organisms in vaginal material (epithelial cells, white blood cells, yeast, bacterial) from spermatozoa.
   
   b. **Task:** Examine the collection of vaginal flora and venereal disease organisms. Record your observations.

4. Lugols:
   a. **Goal:** Observe how cells from other body areas react to Lugol's reagent and differentiate from vaginal epithelial cells.
   
   b. **Task:** Prepare swabs, if not already available, and extract the following swabs: Vaginal, Oral, penile, rectal, dermal.
      
      i. Prepare slides from the swab extracts and stain with Lugol's reagent.
      
      ii. Examine the slides microscopically and note any brown staining caused by the presence of glycogen. Record observations.

5. Menstrual Cycle:
   a. **Goal:** Observe and record any differences in the appearance/morphology of the vaginal cells throughout the menstrual cycle. Observe any differences in the Lugol's cell staining throughout the menstrual cycle.
   
   b. **Task:** Collect vaginal swabs representing approximately seven day intervals of the menstrual cycle (Early proliferative, late proliferative, midsecretory, late secretory). Extract the vaginal swabs from the different stages of the menstrual cycle and prepare 2 sets of slides from the extracts.
      
      i. Stain one set with Christmas Tree stain and the other with Lugol's reagent and examine microscopically. Record observations.

6. Assessment:
   a. The trainee's understanding of the purpose of each test and its strengths and weakness will be evaluated through oral interview and review of the examiner's training note packet.

L. Task 7: Examinations for Saliva
1. **Applied Scientific Reading Materials:**
   a. **Goal:** The goal of this module is to provide practical hands-on instruction and applied knowledge to the trainee on saliva screening procedures.
   b. **Task:** Read the literature reference listed below and review the procedure on amylase diffusion, see BIO.1.BIO.05.
   c. **Safety:**
      i. Read the SDS's for each of the testing reagents.

2. **Amylase Diffusion**
   a. **Goal:** Evaluate amylase activity in saliva and in other physiological fluids.
   b. **Task:** Apply the following samples to an agarose starch gel:
      i. 1:10 dilution of neat saliva
      ii. 1:100 dilution of neat saliva
      iii. 1:200 dilution of neat saliva
      iv. 1:400 dilution of neat saliva
      v. 1:800 dilution of neat saliva
      vi. Urine
      vii. Blood
      viii. Fecal
      ix. semen
      x. Vaginal swab
      xi. Breast milk (if available)
      xii. Saliva stain extracted from cloth
      xiii. Skin surface swab
   c. Incubate overnight and develop with iodine solution. Photograph and record the results. Measure the diameter of the rings.

3. **RSID Saliva Cards**
   a. **Goal:** Evaluate amylase activity in saliva and other physiological fluids.
   b. **Task:** Perform saliva testing using the RSID Saliva cards on the following samples:
      i. 1:100 dilution of neat saliva
      ii. 1:200 dilution of neat saliva
      iii. 1:400 dilution of neat saliva
      iv. 1:800 dilution of neat saliva
v. Urine  
vii. Fecal  
viii. Semen  
ix. Vaginal swab  
xi. Saliva stain extracted from cloth  
xii. Skin surface swab

iii. Record which samples give positive results.

4. **Microscopic Examination**
   
a. **Goal:** Evaluate the cell content in saliva on various surfaces.
   
b. **Task:** Spit in a tube and let saliva liquify for at least an hour refrigerated. Transfer a portion of the neat saliva to a slide and examine the cell content of neat saliva under the microscope.
   
i. Collect saliva from various typical surfaces where saliva may be commonly deposited, such as drink containers, cups, cigarette butts, straws, etc. and licked skin.
   
ii. Collect the saliva onto a swab.
   
iii. Digest 1/2 or the entire swab and examine the cell content under the microscope.

5. **Assessment:**
   
a. The trainee's understanding of the purpose of this test and its strength and weakness will be evaluated through oral interview and review of the examiner's training note packet.

M. **Task 8: Hair Characterization and Suitability for DNA Typing**

1. **Applied Scientific Reading Materials:**
   
a. **Goal:** The goal of this module is to provide practical hands-on instruction and applied knowledge to the trainee on distinguishing a human hair and determining if suitable for DNA typing.
   
b. **Task:** Read the reference literature listed below and review the procedure on Hair Collection and Examination, see [BIO.1.BIO.13](#).
   
   
   
   
   
   
   
   
c. **Safety:**
      
i. Read the SDS's for the mounting media.

2. **Hairs and Fibers**
   
a. **Goal:** Observe morphology differences between a fiber and a hair. Observe differences between animal and human hair. Recognize hairs suitable for DNA analysis.
   
b. **Task:** From the Hair and Fiber example slide collection, obtain the following samples:
i. Examples of various fibers (cotton, polyester, rayon, etc.).

ii. Examples of various common/domestic animal hairs (dog, cat, rabbit, rodent, horse, etc.).

iii. Examples of known human hairs from various races (Caucasian, black, Asian).

iv. Examples of known body region hairs (specifically head and pubic).

v. Utilizing the stereomicroscope (Nikon SMZ 1500), examine the samples listed above and document your observations on a worksheet. Observe the samples under reflected and transmitted light. Note characteristics such as color, structure, root, tip, shaft variations, cuticle, and medulla. Note: you may not be able to observe the scale patterns due to the mount medium.

c. Additionally, examine the samples listed above under bright field microscopy or polarized light and note any additional or different observations.

3. Water mount exercise:
   a. Task: Place dog, cat, and horse hair under a water mount and document your observations as above.
   i. Place several of your own hairs and/or a variety of other donor's hair (head and/or pubic) under a water mount and document your observations as above.
   ii. Determine whether the hairs are anagen, catagen or telogen. Assess whether the hair(s) is suitable for DNA typing and why.

4. Assessment:
   a. The trainee's understanding of the purpose of this practice set will be evaluated through oral interview and review of the examiner's training note packet.

N. Task 9: Clothing/Fabric Examinations

1. Reading Assignments:
   e. Costello, PA., et al., "Do Stab-Cuts Reflect the Weapon which made them?" JFSS 1990; 30(2) 89-95.

2. Training and testing will be conducted on clothing or fabrics with a range of substances commonly encountered in casework.

3. Commonly Encountered Stains:
   a. Goal: To observe and recognize the appearance of various substances on fabric.
   b. Task: Prepare various fabrics, such as colored, printed, cotton, jeans, etc. with various commonly observed stains, such as food, grass stains, juice, etc.
   i. Use various lighting techniques (ALS and Infra-red) and normal room lighting to observe the stains and examine using a stereo-microscope. Evaluate and record characteristics and observations.

   a. Goal: To observe and recognize the appearance of non-blood, red-brown substance on fabric.
   b. Task: Prepare various fabrics, such as colored, printed, cotton, jeans, etc. with various red-brown colored substances, such as ketchup, chocolate, lipstick, blush/eyeshadow, soil-dirt, rust, wood dye, juice, soda, etc. Use various lighting techniques (ALS and Infra-red) and normal room lighting to observe the stains and examine using a stereo-microscope. Evaluate and record characteristics and observations.

5. Fabric Damage:
   a. Goal: To observe and recognize the appearance of various damage to various fabrics.
6. **Bullet Hole/Powder Residue:**
   a. **Goal:** To observe and recognize the appearance of bullet hole damage and GSR.
   b. **Task:** Prepare various fabrics with bullet hole damage and GSR. Observe direction of entry and exit. Use various lighting angles and sources to observe the damage and GSR on the fabric and examine using a stereo-microscope. Evaluate and record characteristics and observations.

7. **Blood/Semen/Saliva/Urine/Fecal Stains**
   a. **Goal:** To observe and recognize the appearance of various body fluid stains on articles of clothing and items.
   b. **Task:** Prepare various clothing items, such as pants, hats, socks, jeans, shirts, underwear with difficult print patterns (plaid, floral, etc) with various body fluid stains and smears. Examine bloodstains and smears on items, such as a knife, hammer, etc. Evaluate and record observations.
   i. Use various lighting techniques (ALS and Infra-red) and normal room lighting to observe the stains.
   ii. Examine using a stereo-microscope to determine the side of deposit of the stain. Evaluate and record characteristics and observations about the stains.

8. **Presumptive Testing**
   a. **Goal:** To practice presumptive testing on stains deposited on fabric and other items.
   b. **Task:** Conduct o-tolidine and AP spot testing on the suspected stains deposited on the clothing from the exercise above. Record observations and results.

9. **Mock Sexual Assault Scenario**
   a. **Goal:** To gain hand-on experience with sexual assault evidence.
   b. **Task:** To be prepared by the trainer: Prepare vaginal, oral, rectal smears, vaginal and rectal swabs, swabs of potential saliva on skin (i.e breast swabs), condom (if available), underwear with biological stains.

10. **Assessment:**
   a. The trainee's understanding of the purpose of this practice set will be evaluated through oral interview and review of the examiner's training note packet.

**O. Task 10: Casework Documentation and Report Writing**

1. **Goal:** To provide instruction to a trainee on reporting analytical results or issuing written notifications according to the laboratory's policy

2. **Tasks:**
   a. The trainee shall receive instruction and training in the following areas:
      i. Case Documentation
      ii. Report Writing
      iii. Technical and Administrative Review

3. The trainee shall
   a. Review a variety of other examiner's completed case notes.
   b. Compile case notes for each of the sets of samples analyzed during training.
   c. Review a variety of completed reports.
   d. Write reports from the training sample sets generated above.
   e. Reports should cover the typical casework, to minimally include:
      i. SAEK reports/notes
      ii. Preliminary Screen reports/notes

4. **Assessment:**
   a. Evaluate and discuss with the trainee his/her understanding of laboratory and Biology Unit's Policies.
P. **Task 11: General Knowledge of Forensics**

1. **Goal:** To familiarize the trainee with other forensic disciplines

2. **Tasks:** The trainee should have general knowledge of other forensic disciplines for the purpose of recognizing, collecting, and preserving evidence. Training may be met by one or a combination of the following:
   a. Formal education in Forensic Science and/or classes, workshops, or webinars focused on other disciplines. Classes need to be documented in the examiner's training binder (electronic or hard copy)
   b. Supplemental Reading/Training
   c. Shadowing analysts in other units
   d. Resources:
      i. Forensic Technology Center of Excellence Webinars: https://forensiccoe.org

3. **Assessment**
   1. Documentation of successful completion/assessment of each task shall be noted on the trainee's Training Log.

Q. **Task 12: Court Room and Legal Procedures**

1. **Goal:** To provide basic instruction and allow trainee to research the legal system of his/her jurisdiction

2. **Tasks:**
   a. The trainee shall receive instruction and training on courtroom procedures and presentation of evidence to cover:
      i. Court structure (trial and appeals courts)
      ii. Format of hearing or trial
      iii. Discovery and Subpoenas
      iv. Rules of evidence (401, 402, 403 hearings)
      v. Admissibility rules (Daubert, Kelly Frye)
      vi. Courtroom demeanor and attire
      vii. Biological screener qualifications
      viii. Ethical responsibility of expert witness
      ix. Evidence/Exhibit presentation
      x. Confidentiality/disclosure of information
      xi. Applicable Criminal and Civil Laws
         1. CA Penal Codes
         2. Crimes against persons
         3. Crimes against person involving sexual assault, against public decency and good morals
         4. Crimes against property
         5. Statute of Limitations
   b. Observe courtroom testimony
   c. The trainee will prepare a statement of qualifications.
   d. The trainee will participate in mock testimony that includes direct and cross examination as well as the introduction of evidence/exhibits as part of the competency test.

3. **Reading Assignments:**

e. CA Peace officers Legal Sourcebook (found on CopWare)

4. Assessment
   a. This module should be completed by all trainees.
   b. Completion of the module will include documentation of completion of the relevant reading assignments.

R. Task 13: Final Evaluation

1. Competency Test:
   a. Following the completion of training, individuals will be competency tested to assess the trainee's skills and understanding of the biology screening procedures and to assess the effectiveness of the training.
   b. Successful completion of the training program and a competency test is required prior to the authorization of the trainee performing their job duty(s).

   c. Task:
      i. A test of unknown samples representative of the type of samples the trainee will be analyzing on the job.
      ii. A written test report (if the trainee will be issuing reports)
      iii. A written or oral test that assesses understanding of the fundamental scientific knowledge of biological screening.
      iv. Mock testimony questions or a mock court.

   d. Assessment
      i. Competency test will be reviewed and documented in LIMS.
      ii. Authorization will be given to the trainee after successful completion.
      iii. Authorization will be documented on the Biological Screening Training Log.

S. Assessing the Effectiveness of Training

1. The following will be used to evaluate the effectiveness of the training program.
   a. Technical and administrative review of all casework
   b. Proficiency testing
   c. Court critiques
   d. Yearly performance evaluations

T. Retraining and Remedial Training

1. Retraining may be required when an examiner has been absent greater than 12 months from performing casework or when there has been a significant change to a procedure.

2. Remedial training may be required if technical issues arise during training, competency testing, proficiency testing, courtroom testimony, or casework. A competency test in the area of weakness may be re-issued, if deemed necessary. A record of the remedial will be documented through a QA Action.
   a. A modified training program will be created by the Supervisor or training coordinator and documented on the training log.
   b. The reason for the retraining/remedial training will also be documented on the training log.

END OF DOCUMENT
I. The goal of the DNA training program is to provide a trainee the knowledge, skills, and ability to perform DNA STR testing on casework samples.

A. Intent of the Training Program
   1. To develop knowledge, skills, and abilities in the area of Forensic DNA culminating in the ability to perform DNA testing on casework samples.
   2. To develop the necessary skills required for performing DNA testing, such as evidence handling, using proper equipment, analyzing samples, interpreting results, etc.
   3. To develop the knowledge necessary to provide expert testimony in Forensic DNA testing in court.

B. Overview of the Training Program
   1. Training is required for a new DNA Analyst/Technician or a current employee new to DNA analysis, prior to beginning casework. Training will be tailored to an employee's job duties and to the extent they will conduct casework, such as a technician versus a DNA analyst.
   2. Training will entail literature readings, instruction, demonstrations, hands-on practical exercises, and court training. Training is administered in a modular format and assessments are built into each module which allows for the trainee to conduct casework in any of the areas for which the trainee was trained and competency tested. Training may be supplemented by external training, such as college coursework, workshops or other formal training courses.
   3. A new DNA analyst must undergo a minimum of six months of training in accordance with the FBI Director's Quality Assurance Standards. The actual length of the training period may vary and will be left to the determination of the DNA Technical Lead/Supervisor or training coordinator, but should be approximately one to two years.
   4. Training may be abbreviated for an analyst with previous training and prior forensic DNA casework experience. Records of the trainee's prior training and experience will be reviewed by the DNA Technical Leader/Supervisor and will be maintained in the LIMS Training Module. A copy may also be maintained in the examiner's training binder.
   5. Training will be given under the guidance of the DNA Technical Leader/Supervisor or an experienced DNA analyst may act as a training coordinator. The trainer is expected to communicate with the trainee throughout the program, offering feedback and guidance.
   6. Separate training will be given for biology screening, see Biology Training Manual BIO.4.TRAIN.01.

C. Educational Requirements:
   1. The roles of individuals in the Biology unit and the educational requirements for each role is documented in BIO.5.QAQC.05.

D. Expectations of the Trainee
   1. The trainee is expected to keep a notebook/binder of information compiled during the training program, including practical exercises.
   2. The trainee will document their progress on the DNA Training Log, BIO.1.BIOF.05, to include the date each portion of the training was completed, the trainee's initials, and the date and initials of the trainer. The training records will be retained in LIMS and may also be maintained in the trainee's training binder. Training records will be retained by the Laboratory, minimally 10 years, according to Division policy "Control of Records" FSD.44. (QAS 3.2)
   3. Trainees are expected to communicate any concerns about their training to the training coordinator and/or DNA Technical Leader/Supervisor.

E. Guidelines for Competency
1. To demonstrate the trainee's knowledge, skills, and abilities, the trainee will undergo a competency test to the extent they received training, prior to participating in casework or DNA testing activities. See BIO.5.QAQC.13 for Biology's procedures regarding competency testing. Criteria for successfully passing the competency test will be documented prior to the individual receiving the competency test. A record of the competency test will be tracked and maintained through LIMS.

2. The signatures of the DNA Technical Leader/Supervisor on the training log will signify approval of the training and successful completion of the competency test. Approval signifies authorization for the trainee to conduct casework using all the equipment, instrumentation and procedures to the extent they received training and were competency tested.

3. If the trainee is expected to issue laboratory reports and has met the report writing competency requirements, the analyst will also be considered to be authorized to issue reports and give opinions and interpretations in the areas(s) for which they received training and competency.

4. The trainee will enter into the proficiency test cycle within 6 months of the authorization to conduct casework.

F. Task 1. Laboratory Introduction

New employees undergo an orientation program prior to the commencement of training. The orientation covers a variety of topics, such as safety, ethics, quality assurance. Refer to FSDF.01 for a list of topics covered under orientation. Related topics that are specific to the Biology Unit operation and procedures are addressed in the below training plan:

1. **Goal:** To familiarize the trainee with the DNA manuals and the expectations of the training program

2. **Tasks**
   a. Review and discuss the DNA Training Manual and Plan
   b. Read SWGDAM's Training Guidelines (2013), Reference Training document 44
   c. Review the DNA Analytical Procedures Manual
   d. Introduction to the Quality Assurance/Quality Control Program
      i. Review the Biology Unit's QA/QC Manual
      ii. Review the Forensic Services Division Manual
      iii. Instruction/Discussion on Contamination Controls/Prevention.
   e. Review the FSD Safety Manual
      i. Bloodborne Pathogen Training
      ii. Chemical Hygiene Training
      iii. Chemical Waste Disposal Training
   f. Orientation to the laboratory facility and security features.
   g. Description of the organization and management
      i. Goals and Objectives
      ii. Code of Ethics
      iii. Chain of Command of the Forensic Services Division
      iv. Laboratory administrative policies
   h. Ethics and Bias as it relates to forensic DNA
      i. Read: Budowle, A perspective on Errors, Bias, and Interpretation in Forensic Sciences, Training Document 54

3. **Assessment**
   a. This module should be completed by analysts, technicians, and laboratory support personnel.
   b. Documentation of successful completion/assessment of each task shall be noted on the trainee's DNA Training Log.
   c. Documentation of acknowledgement of laboratory policies and protocols is documented through PowerDMS

G. Task 2. Evidence/Sample Handling and Control

1. **Goal:** Develop an understanding of sample and/or evidence control in the forensic laboratory.
2. **Tasks:**
   a. Receive instruction on the following, as applicable:
      i. Sample and/or evidence collection, packaging, and storage
      ii. Chain of custody, receiving, and handling samples and/or evidence
      iii. Contamination Controls/Prevention.
      iv. Case acceptance policy/Case management
      v. Case workflow
      vi. Consumption of samples and/or evidence
      vii. Distinction between evidence and work product
      viii. Laboratory documentation policy (paper and/or electronic)
   b. Review LIMS presentation (QAT.09) and LIMS DOS and DONT'S (QAT.09.01) in powerDMS.
   c. **Assessment:**
      a. This module should be completed by analysts, and technicians.
      b. Documentation of successful completion/assessment of each task shall be noted on the trainee's DNA Training Log.

H. **Task 3. Fundamental Scientific Knowledge**

1. **Goal:** To ensure that a trainee has or is provided the formal education and the working knowledge of the fundamental scientific basics of forensic DNA analysis.

2. **Tasks/Reading Assignments**
   g. Current Quality Assurance Standards for Forensic DNA Testing Laboratories (Training Reference 5).

3. **Assessment**
   a. Module should be completed by DNA analysts and technicians.
   b. Documentation of successful completion/assessment of each task shall be noted on the trainee's DNA Training Log.

I. **Task 4. Applied Scientific Knowledge**

1. **Goal:** To educate the trainee on the specific knowledge related to the field of forensic DNA analysis. The level of detail should be applicable to the trainee's job description.

2. The following bibliography represents a sample list of resources that may be helpful to the trainer in defining the breadth and scope of the materials for the trainee's reading. This list is not meant to be all inclusive.

3. **Tasks/Reading Assignments:** Wherever possible, instruction in theoretical knowledge areas should be supplemented through continuing education courses available through sources such as the California Criminalistics Institute. LCN testing and mtDNA analysis are not conducted in this laboratory, and the training provided is merely foundational. Articles describing legacy systems such as PM+DQA1 and D1S80 should be read for historical perspective. Source material may be found in the following location **G:Serology/Literature References.**
   a. **Forensic applications of genetic polymorphisms**
      i. For. Sci. Handbook III, Chap. 6 (Lab Library GC 165)
      ii. Repetitive DNA and Human Genome Variation . . .Training, document 6
b. **Historical DNA Methods**
   i. **RFLP:** Forensic Science Handbook III, Chap 7 (Lab Library GC 165)
   ii. **RFLP:** DNA Analysis by RFLP…; Training Document 10
   iii. **Polymarker (PM) + DQA1:** Genetic Analysis of Amplified DNA…, Training document 13
   iv. **D1S80:** Validation of the AmpliFLP D1S80…; Training document 16

c. **DNA Extraction**
   i. Application of DNA polymorphisms to sperm; Training document 7
   ii. 26 DNA Extraction Strategies…; Training document 8

d. **Real-Time PCR Quantitation**
   i. The PowerQuant System…; Training Document 46
   ii. A Study of PCR Inhibition Mechanisms Using Real Time PCR; Training document 45

e. **Polymerase Chain Reaction (PCR)-based methods**
   i. For. Sci. Handbook III, Chap 8 (Lab Library, GC 165)
   ii. PCR Technology, Chap 1 and 2 (Lab Library, PF 62)
   iii. Preferential PCR Amplification of Alleles; Reference Training document 11
   iv. Avoiding False Positives…; Reference Training document 12

f. **Short Tandem Repeats (STR)**
   i. DNA Microsatellites: Agents of Evolution?; Reference Training document 18
   ii. Analysis and Interp. of STR microvariants…; Reference Training documents 19
   iii. Sequence analysis and characterization…; Reference Training document 20
   iv. Developmental Validation of PowerPlex…; Training document 47
   v. Validation of STR Typing…, Training document 48

g. **Population Genetics and Forensics Statistics**
   i. The Evaluation of Forensic DNA Evidence (Lab Library PF 96)
   ii. Allele frequencies of 15 STR loci; Reference Training document 34
   iii. Population data on the 13 CODIS…; Reference Training document 35
   iv. CODIS STR loci data…; Reference Training document 36
   v. Expanded CODIS Core…; Training document 50
   vi. Variability of New STR Loci; Training document 49
   vii. ISFG-Recs. on biostatistics in paternity testing; Reference Training document 38
   viii. Popstats Paternity stats; Reference Training document 39

h. **Mixture Interpretation**
   i. Analysis and Interp. of Mixed…; Training document 32
   ii. Mixture Interp. Defining…; Training document 33
   iii. Wang-Least Square…; Training document 52
   iv. Gill…Recommendations on the interpretation of mixtures; Training document 2
   v. The German Stain Commission: Recommendations from the interpretation of mixed stains; Training document 3

i. **Probabilistic Genotyping**

j. Touch DNA

i. Swabbing Firearms.; Training document 31

ii. Obtaining DNA from fired and unfired ammunition; Training document 51

iii. Recovery of DNA from Latent...; Training document 17

iv. The Influence of Selected Fingerprint...; Training document 23
k. Other Forensic DNA Topics (i.e Paternity, Low Copy Number, Y-STRs)
   i. mtDNA: Extraction, PCR Amplification and Sequencing of mtDNA. . . ; Reference Training document 21
   ii. mtDNA: Validation of mtDNA. . . ; Training document 22
   iii. Prenatal and newborn paternity testing. . . ; Reference Training document 37
   iv. LCN: Amplification of Low Copy. . . ; Reference Training document 40
   v. LCN: Low Copy Number Consideration. . . ; Reference Training document 41
   vi. YSTRs: Evaluation of Y-chromosomal STRs. . . ; Reference Training document 42
   vii. YSTRs: Y-STR Interpretation. . . ; Training document 43
   viii. Rapid DNA: Evaluation of the RapidHIT. . . ; Training document 53
   ix. Rapid DNA: Internal Validation of the DNAscan/ANDE. . . ; Training Document 56

4. Assessment:
   1. This module should be completed by DNA analysts.
   2. Acknowledgement of the trainee's reading will be documented and the trainee's understanding of fundamental scientific knowledge will be evaluated through the competency test (written test of knowledge).

J. Task 5. Laboratory Analysis

1. Goal: To provide practical instruction to the trainee on technologies, methodologies, and platforms used in the laboratory. Training will include instruction, demonstration of testing methods by qualified analysts, observation of trainee performing testing methods, and directed practical exercises for each of the relevant work areas. When available, training will be supplemented with continuing education through external sources such as the California Criminalistics Institute.

2. Tasks
   a. Instruction, Demonstration and Observation
      i. Digestion: Differential (manual/robotic) and straight digestion.
      ii. EZ1 Extraction
      iii. Real time PCR (manual and robotic setup)
      iv. Amplification with current kits used in the laboratory (manual and robotic setup)
      v. Genetic Analyzer: Sample setup (manual and robotic) and instrument setup
      vi. Genetic Analyzer maintenance
   b. Practical Exercises DNA analyst training shall include practical exercises on a minimum of 50 human biological "case-like" samples. The type of samples included must vary, reflecting the range, type, and complexity of casework analyses routinely handled by his/her laboratory duties. No more than 1/3 of the samples tested should be included in the same sample type category. An individual with prior DNA casework experience may perform practical exercises on less than 50 samples.
      i. Sample Types:
         1. Bloodstains (5-10)
         2. Oral swabs (5-10)
         3. Hair (5-10)
         4. Semen or Mixed Semen/Non-sperm DNA (Differential digestions) (10-15)
         5. Low Level samples (touch and wearers DNA) (10-15)
         6. Fingernails
         7. Bone and/or teeth
         8. Degraded DNA (if possible)
         9. Select samples will include mixtures of DNA sources to be typed in using approved PCR typing methodologies below.
      ii. Extraction
1. Straight Digestions
3. Differential Digestion using the Versa 1100
4. EZ1 Extraction

iii. **Quantitation**
1. Perform DNA quantification using the PowerQuant kit and using the 7500 with HID software
   1. Setup manually and also using the liquid handling robot

iv. **Amplification**
1. Robotic sample normalization
2. Experience setting up amplification reactions using all kits currently in use for casework by the Biology Unit on the ProFlex Thermal Cycler.
3. Kits: PowerPlex Fusion 6C, PowerPlex Fusion 6C Direct amplification
4. Differing amounts of target DNA should be amplified (16pg, 32pg, 64pg, .125ng, 0.5ng, 1ng)
5. Amplifications of DNA mixtures should be performed (two to four contributors 0.25ng to 1.25ng)
6. Direct amplification of buccal swabs and blood on FTA
7. Sample concentration using the evaporative centrifuge
8. Setup manually and also using the liquid handling robot

v. **CE STR Analysis**
1. 3500 manual and robotic sample setup
2. 3500 instrument setup
3. 3500 routine maintenance

3. **Reading Assignments**
   a. **Kit manufacturer's literature**
      i. EZ1 DNA Investigator Handbook; Training document 24
      iii. 7500 Real-Time HID Software User Manual; Training document 26
      iv. PowerPlex Fusion 6C Amplification Kit User Manual; Training document 27
      v. ProFlex User Manual; Training document 28
      vi. ABI 3500 User Manual, Training document 29
      vii. Hamilton Nimbus User Manual, if applicable; Training document 55
   b. **Laboratory's Validation Studies**
      i. EZ-1 Bio Robot Validation Summary
      ii. Selective Degradation Differential Digestion Validation Summary
      iii. PowerQuant Validation Summary
      iv. Fusion 6C/3500/Genemapper ID-X Validation Summary
      v. Hamilton Nimbus Validation Summary
      vi. Fusion 6C Direct Amplification Validation Summary
      vii. Selective Degradation Differential using the Versa 1100

4. **Assessment**
   1. This module should be completed by DNA analysts and technicians to the extent in which they perform casework.
2. Assessment will occur through review of the trainees compiled DNA data. Documentation of successful completion/assessment of each task shall be noted on the trainee's DNA Training Log.

K. Task 6. Interpretation/Analysis and Case Documentation/Reports

1. **Goal:** To provide practical instruction to the analyst on interpretation of DNA analysis for the technologies, methodologies and platforms used in the laboratory in accordance with the analyst’s job responsibilities and the extent to which the analyst will participate in DNA analysis. To provide instruction to an analyst on reporting analytical results or issuing written notifications according to the laboratory's policy

2. **Tasks:**
   a. The analyst shall receive instruction and training in the following areas. (Training may include the use of presentations, webinars, and continuing education coursework).
      i. Mixture Interpretation (Binary and using STRmix)
      ii. Statistical Analysis (RMP, mMRP, and Likelihood Ratios)
      iii. Paternity/Kinship analysis
      iv. Case Documentation (analyst and technician)
      v. Report Writing
      vi. Technical and Administrative Review (analyst and technician)
   b. The analyst should perform the following on practice casework samples (at least 10 sets of samples):
      i. Data interpretation using GeneMapper ID-X
      ii. Analysis of single source samples
      iii. Analysis of mixture samples
      iv. Practice using STRmix on single source and mixtures of up to four people
      v. Practice using RMP/mRMP statistical workbook
      vi. Practice using CoSTaR software
   c. **Case Documentation**
      i. Compile case notes for each of the sets of samples analyzed during training. (analyst and technician)
   d. **Report Writing**
      i. Write reports from the training sample sets generated above.
      ii. Reports should cover the typical casework analysis and interpretations expected in casework, to minimally include:
         1. Sexual Assault evidence analysis (differential digests)
         2. Paternity analysis
         3. Mixture analysis
   e. **Reading Assignments:**
      b. Statistical Workbook Validation Summaries
      c. Estimation of STRmix Parameters Summary
      d. STRmix Validation Summary
      e. STRmix v.2.6 Operation Manual 4/8/19
      f. STRmix v.2.6 Users Manual 8/18 pg 7-52, 66-92, 207-212
      h. Committee on DNA Forensic Science, National Research Council I (1992) DNA Technology in Forensic Science. Chapters 4 and 7 Lab library PF 82.

3. **Assessment:**
   1. This module should be completed by DNA analysts to the extent in which they perform casework.
   2. Assessment will occur through review of the trainees compiled DNA data, case packets, and reports. Documentation of successful completion/assessment of each task shall be noted on the trainee's DNA Training Log.

L. **General Knowledge of Forensics**
   1. **Goal:** To familiarize the trainee with other forensic disciplines
   2. **Tasks:** The analyst should have general knowledge of other forensic disciplines for the purpose of recognizing, collecting, and preserving evidence. Training may be met by one or a combination of the following:
      a. Formal education in Forensic Science and/or classes, workshops, or webinars focused on other disciplines. Classes need to be documented in the examiner's training binder (electronic or hard copy)
      b. Supplemental Reading/Training
      c. Shadowing analysts in other units
      d. **Resources:**
         i. Forensic Technology Center of Excellence Webinars: https://forensiccoe.org
   3. **Assessment**
      1. This module should be completed by DNA analysts.
      2. Documentation of successful completion/assessment of each task shall be noted on the trainee's DNA Training Log.

M. **Task 7. Courtroom and Legal Procedures**
   1. **Goal:** To provide basic instruction and allow trainee to research the legal system of his/her jurisdiction
   2. **Tasks:**
      a. Instruction on courtroom procedures and presentation of evidence to cover:
         i. Court structure (trial and appeals courts)
         ii. Format of hearing or trial
         iii. Discovery and Subpoenas
         iv. Rules of evidence (401, 402, 403 hearings)
         v. Admissibility rules (Daubert, Kelly Frye)
         vi. Courtroom demeanor and attire
         vii. DNA analyst qualifications
         viii. Ethical responsibility of expert witness
         ix. DNA Database legal authority (State and Federal)
         x. Confidentiality/disclosure of information
         xi. Applicable Criminal and Civil Laws
            1. CA Penal Codes
            2. Crimes against persons
            3. Crimes against person involving sexual assault, against public decency and good morals
            4. Crimes against property
            5. Statute of Limitations
      b. Observe courtroom testimony or complete a testimony course.
      c. The analyst will prepare a statement of qualifications.
d. The analyst will participate in mock testimony that includes direct and cross examination as well as the introduction of evidence/exhibits as part of the competency test

3. Reading Assignments:
   e. CA Peace officers Legal Sourcebook (found on CopWare)

4. Assessment
   a. This module should be completed by analysts/technicians.
   b. Completion of the module will include documentation of completion of the relevant reading assignments.

N. Task 8. Final Evaluation: Following the completion of training, all analyst's, technicians, and support personnel will be competency tested to assess the trainee's skills and understanding of the DNA Analytical Procedures and to assess the effectiveness of the training.
   1. Competency Test: Successful completion of the training program and a competency test is required prior to the authorization of the trainee performing their job duty(s).
      a. Task:
         i. A test of unknown samples representative of the type of samples the trainee will be analyzing on the job.
         ii. A written test report (if the trainee will be issuing reports)
         iii. A written or oral test that assesses understanding of the fundamental scientific knowledge of forensic DNA analysis.
         iv. Mock testimony questions or a mock court
      b. Assessment
         i. Competency test will be reviewed and documented in LIMS.
         ii. Authorization will be given to the trainee after successful completion.
         iii. Authorization will be documented on the DNA Training Log.

O. Assessing the Effectiveness of Training
   1. The following will be used to evaluate the effectiveness of the DNA training program.
      a. Technical and administrative review of all DNA casework
      b. Proficiency testing
      c. Court critiques
      d. Yearly performance evaluations

P. Retraining and Remedial Training
   A. Retraining may be required when an examiner has been absent greater than 12 months from performing casework or when there has been a significant change to a procedure.
   B. Remedial training may be required if technical issues arise during training, competency testing, proficiency testing, courtroom testimony, or casework. A record of the remedial will be documented through a QA Action.
      A. A modified training program will be created by the DNA Technical Lead/Supervisor or training coordinator and documented on the DNA training log.
      B. The reason for the retraining/remedial training will also be documented on the DNA training log.
      C. The individual shall successfully complete a competency test prior to returning to participation in casework analysis.
I. The goal of the DNA training program is to provide a trainee the knowledge, skills, and ability to perform DNA Y-STR testing on casework samples.

A. Intent of the Training Program
   1. To develop knowledge, skills, and abilities in the area of Y-chromosome DNA testing culminating in the ability to perform Y-STR testing on casework samples.
   2. To develop the necessary skills required for performing Y-STR testing, such as using proper equipment, analyzing samples, interpreting results, etc.
   3. To develop the knowledge necessary to provide expert testimony on Y-STR testing in court.

B. Overview of the Training Program
   1. This training program is intended for technicians/analysts that are already trained to perform DNA STR testing. Training will be tailored to an employee's job duties and to the extent they will conduct casework, such as DNA technician or DNA analyst.
   2. Training will entail reading literature, instruction, hands-on practical exercises, and court training.
   3. Training will be given under the guidance of the DNA Technical Leader/Supervisor or an experienced DNA analyst may act as a training coordinator. The trainer is expected to communicate with the trainee throughout the program, offering feedback and guidance.

C. Expectations of the Trainee
   1. The trainee will keep a notebook/binder of information compiled during the training program, including practical exercises.
   2. The trainee will document their progress on the Y-STR Training Log, to include the date each portion of the training was completed, the trainee's initials, and the date and initials of the trainer. The training records will be retained in LIMS and may also be maintained in the trainee's training binder. Training records will be retained by the Laboratory, minimally 10 years, according to Division policy "Control of Records" FSD.44. (QAS 3.2)
   3. Trainees will communicate any concerns about their training to the training coordinator and/or DNA Technical Leader/Supervisor.

D. Guidelines for Competency
   1. To demonstrate the trainee's knowledge, skills, and abilities, the trainee will undergo a competency test to the extent they received training, prior to participating in casework or DNA testing activities. See BIO.5.OAOC.13 for Biology's procedures regarding competency testing. Criteria for successfully passing the competency test will be documented prior to the individual receiving the competency test. A record of the competency test will be tracked and maintained through LIMS.
   2. The signatures of the DNA Technical Leader/Supervisor and Trainer on the training log will signify approval of the training and successful completion of the competency test. Approval signifies authorization for the trainee to conduct casework using all the equipment, instrumentation and procedures to the extent they received training and were competency tested.
   3. If the analyst is expected to issue laboratory reports and has met the report writing competency requirements, the analyst will also be considered to be authorized to give opinions and interpretations in the areas(s) for which they received training and competency.
   4. The analyst will enter into the proficiency test cycle within 6 months of the authorization to conduct casework.

E. Reading Assignments
4. CCCSO Y-STR Internal Validation Summary

F. Laboratory Analysis

1. **Goal**: To provide practical instruction to the trainee on technologies, methodologies, and platforms used in the laboratory. Training will include instruction, on the Y-STR testing methods, and practical exercises for each of the relevant work areas. When available, training will be supplemented with continuing education through external sources such as the California Criminalistics Institute.

2. **Tasks**:
   a. **Instruction**
      i. Receive instruction on Y-STR Testing/Analysis
      ii. May include observing a demonstration of Y23 amplification set up and
      iii. performing Y23 amplification set up while being observed by a trainer
   b. **Practical Exercises** DNA analyst training shall include practical exercises on "case-like" samples. The type of samples included must vary, reflecting the range, type, and complexity of casework analyses routinely handled by his/her laboratory duties.
      i. Single source male DNA samples
         1. At the following target amounts: 0.032ng, 0.064ng, 0.125ng, and 0.250ng
      ii. Non-probative Mixed Semen/Non-sperm DNA (Differential digestions)
      iii. Male/Female Mixtures
         1. At different male:female ratios such as 1:100, 1:500, or higher
      iv. Mixtures of Two Males
         1. Targeting several different amounts of male DNA: 0.125ng, 0.250ng, and 0.5ng
         2. At the following ratios: 1:3 1:4, 1:10, 1:20 or similar

3. **Assessment**:
   a. Assessment will occur through review of the trainee's compiled DNA data. Documentation of successful completion/assessment of each task shall be noted on the trainee's DNA Training Log.

G. Interpretation/Analysis and Case Documentation/Reports

1. **Goal**: To provide practical instruction to the analyst on the interpretation of Y-STR analysis in accordance with the analyst's job responsibilities and the extent to which the analyst will participate in DNA analysis. To provide instruction to an analyst on reporting analytical results according to the laboratory's policy.

2. **Tasks**:
   a. The analyst shall receive *instruction and training* in the following areas:
      i. Mixture Interpretation
ii. Statistical Analysis

iii. Case Documentation (analyst and technician)

iv. Reporting Results/Report Writing

v. Technical and Administrative Review (analyst and technician)

vi. US YSTR database

b. The analyst should perform the following on practice casework samples:

i. Data interpretation using Genemapper ID-X

ii. Analysis of single source samples

iii. Analysis of mixture samples

iv. Practice using the statistical program

c. Case Documentation

i. Compile case notes for each of the sets of samples analyzed during training. (analyst and technician)

d. Report Writing

i. Write reports from the training sample sets generated above

ii. Reports should cover the typical casework analysis and interpretations expected in casework.

3. Assessment:

a. This module should be completed by DNA analysts to the extent in which they perform casework.

b. Assessment will occur through review of the trainees compiled DNA data, case packets, and reports. Documentation of successful completion/assessment of each task shall be noted on the trainee's DNA Training Log.

H. Final Evaluation: Following the completion of training, all analyst's, technicians, and support personnel will be competency tested to assess the trainee's skills and understanding of the DNA Analytical Procedures and to assess the effectiveness of the training.

1. Competency Test: Successful completion of the training program and a competency test is required prior to the authorization of the trainee performing their job duty(s). A competency test will consist of the following:

a. A test of unknown samples representative of the type of samples the trainee will be analyzing on the job.

b. A written test report (if the trainee will be issuing reports)

c. A written or oral test that assesses understanding of the fundamental scientific knowledge of forensic DNA analysis.

d. Mock testimony questions or a mock court

2. Assessment:

a. Competency test will be reviewed and documented in LIMS.

b. Authorization will be given to the trainee after successful completion. Authorization will be documented on the DNA Training Log.

I. Assessing the Effectiveness of Training

1. The following will be used to evaluate the effectiveness of the DNA training program.

a. Technical and administrative review of all DNA casework

b. Proficiency testing

c. Court critiques

d. Yearly performance evaluations

J. Retraining and Remedial Training

1. Retraining may be required when an examiner has been absent greater than 12 months from performing casework or when there has been a significant change to a procedure.
2. **Remedial** training may be required if technical issues arise during training, competency testing, proficiency testing, courtroom testimony, or casework. A record of the remedial will be documented through a QA Action.
   a. A modified training program will be created by the DNA Technical Lead/Supervisor or training coordinator and documented on the DNA training log.
   b. The reason for the retraining/remedial training will also be documented on the DNA training log.
   c. The individual shall successfully complete a competency test prior to returning to participation in casework analysis.

END OF DOCUMENT
BACKGROUND

The DNA Identification Act of 1994 established the DNA Advisory Board (DAB) and was composed of a panel of professionals from the public and private sectors. The DAB first convened in 1995 and set out to develop and revise recommended standards for quality assurance. The first DNA Quality Assurance Standards (QAS) were developed in October 1998 and have become benchmarks for assessing the quality practices and performances of DNA laboratories across the country. When the Federal DNA Advisory Board's statutory term expired, the responsibility for recommending revisions to the QAS was transferred to the Scientific Working Group on DNA Analysis Methods (SWGDAM).

The DNA Identification Act of 1994 also requires that the FBI ensure that all DNA laboratories that are federally operated, receive federal funds or participate in the National DNA Index System (NDIS) demonstrate compliance with the QAS. Documentation of the laboratory's compliance with these established standards is measured through an audit process which is conducted yearly. The QAS audit document defines and interprets each standard, and is structured so that criteria, which overlap with ASCLD/LAB, are consistent for interpretation purposes.

GOALS AND OBJECTIVES

One of the Biology Unit's primary roles is the examination and identification of biological materials, such as hair, tissue, bones, teeth, blood, semen, and other bodily fluids. Not all biological evidence is readily visible, thus the key to any examination is the ability to detect the biological evidence.

One or more types of biological evidence may be associated with any one case, and each type of biological evidence may have a unique importance, as well as its own probative value. The Biology Unit plays a role in assessing and conveying the significance of the evidence to the criminal justice community.

DNA, which can be obtained from a number of different biological materials, is utilized by the Biology Unit to identify the human source of the biological material through the use of DNA typing methods.

The goal of the Biology Unit is to provide a high quality work product that can be effectively employed by, communicated to, and relied upon by the criminal justice system.

The field of forensic science is constantly changing with developments in new techniques, refinements to existing capabilities, and providing new capabilities. The Biology Unit's quality assurance program is a means to guide, direct, assess, and monitor (on an ongoing basis) the quality, integrity and reliability of the techniques, procedures, and capabilities currently used in the Biology Unit, as well as those that may be utilized in the future.

OVERVIEW AND SCOPE

The Laboratory is accredited by ASCLD/LAB (American Society of Crime Lab Directors Laboratory Accreditation Board). The Biology Unit acknowledges and abides by the DNA Quality Assurance Standards (QAS) for Forensic DNA Testing Laboratories.

The Biology Unit has developed a quality program to ensure the accuracy and reliability of work performed in the unit. The quality system is documented primarily in the Quality Assurance/Quality Control Chapter of the Biology Technical Unit Manual. The Biology Technical Unit Manual consists of the following chapters:

1. Biology Procedures (chapter, BIO.1.BIO.et al)
2. DNA Analytical Procedures (chapter, BIO.2.DNA.et al) QAS 9.1.1
3. CODIS (chapter, BIO.3.CODIS.et al)
4. Training (chapter, BIO.4.TRAIN.et al)
5. Biology Unit Quality Assurance/Quality Control (chapter, BIO.5.QAQC.et al)
6. Forms (BIO.1.BIO.F.et al & BIO.5.QAQCF.et al)

The Biology Unit's policies, procedures and forms are controlled according to the Division's document control policy FSD.44. The documents are controlled to prevent procedural drift which could lead to the misuse or misunderstanding of procedures and methods.

The DNA analytical procedures are reviewed annually as part of the annual Quality Review of the Biology Unit at the direction of the DNA Technical Leader. QAS 9.1 The review is documented in a memo or other form of interoffice communications. For additional information on the annual Quality Review, refer to BIO.5.QAQC.12. Supplemental quality assurance measures can be found in the Division Manual (FSD.et al) & Division Quality Assurance Manual (QA.et al).

A current version of the DNA Quality Assurance Standards can be referenced electronically through the laboratory's document control system (PowerDMS) or on the Biology's Unit network folder.

END OF DOCUMENT
I. Organization
   A. An organizational chart with the names of current personnel and their specific position or assignment is maintained on the Biology Unit's network folder. QAS 4.1.1, 4.1.5
   B. The Biology unit has greater than two qualified DNA analysts and will maintain a minimum of two full time employees qualified to do DNA analysis among the technical staff of the Biology Unit. QAS 4.1.4
   C. A Division-wide organization chart and chain of command is defined in the Division Manual under section (FSD.02)

II. Management
   A. Job descriptions within the Division are defined in the Division Manual under section (FSD.03). Job descriptions for the following positions are defined in the Division Manual under the following sections:
      1. Chief of Forensics (FSD.04)
      2. Section Manager (FSD.05)
III. Roles maintained within the Biology Unit

A. **Biology Unit Supervisor:** The Biology Unit has at least one Supervisor position in the unit. The Supervisor is responsible for directly supervising technical and support personnel in the Biology unit. The position and responsibilities are defined in the Division Manual under section FSD.06.

B. **DNA Technical Leader:** The Biology Unit has one DNA Technical Leader position in the unit. The DNA Technical Lead is responsible for the technical operations. The position and responsibilities are defined in the Biology Technical Unit Manual under section (BIO.5.QAQC.05). QAS 4.1.2

1. The Division has a documented contingency plan, approved by laboratory management, in the event of a vacancy in the DNA Technical Leader position. A copy of the plan is kept within the Biology Unit. QAS 4.1.6

2. The Chief may appoint a new DNA Technical Leader at any time depending on the needs of the Division though the importance for stability in this position will be taken into consideration. In the event that the technical leader position is vacated and there is no individual in the laboratory who meets the requirements of this standard to serve as a technical leader, the laboratory will immediately contact the FBI and submit their contingency plan within 14 days to the FBI for its approval. DNA casework will cease until the contingency plan or a new DNA Technical Leader is set in place.

C. **Casework CODIS Administrator:** To meet NDIS requirements, the Biology Unit has a casework CODIS Administrator position in the unit. The CODIS Administrator position and responsibilities are defined in the CODIS Manual (BIO.3.CODIS.05). QAS 4.1.3

END OF DOCUMENT
I. Personnel in the Biology Unit will possess education, training, and experience in accordance with ANAB and FBI Quality Assurance Standards for Forensic DNA Laboratories.

A. Job Descriptions

1. The FSD manual section on Job Descriptions (FSD.03) sets policy on general job descriptions for all employees of the division. The County Human Resources Department maintains written job descriptions for each job title within the County. The Biology Unit maintains personnel with specific roles and with these roles they must meet additional requirements as specified in the FBI DNA Quality Assurance Standards for Forensic DNA Testing. The requirements of the Biology Unit as well as the qualifications, responsibility, and/or authority of each position is described below.

2. Biological Screener

   a. Role: A biological screener performs casework requiring the identification and collection of physiological fluids, preparation of case reports, and expert testimony. Additional duties may include preparation of reagents, validation, calibration of equipment and other quality control checks, and ordering supplies.

   b. Qualifications: A biological screener will be an employee of the Contra Costa Sheriff's Office and have, at a minimum, the following education, experience, and training:

      1. A bachelor's degree in a natural science or a closely related field.

      2. Prior experience or training (in-house or external) in biological screening to include; hands-on testing in the types of procedures performed at the laboratory.

      3. A competency test in the category(s) of testing to be performed in casework.

   c. Authorization:

      1. Upon successful completion of training and competency testing, an examiner will be authorized to access evidence storage, reagents and supplies necessary to perform casework, use all equipment, instrumentation and procedures they were trained to use, perform validation studies, issue reports, give opinions and interpretations associated with the scope and category(s) of tests the examiner has been qualified to perform.

      2. The examiner is authorized to release results to the client agency and provide expert testimony.

      3. Acknowledging successful completion of training and competency testing and authorization to conduct casework will be documented on the examiner's training log.

3. Technicians QAS 5.5

   a. Role: Technicians conduct a variety of duties including preparation of reagents, calibration of equipment, quality control checks, validation and performance verification, and ordering supplies. A technician may also assist with processing casework samples through analytical methods not involving interpretation and analysis.

   b. Qualifications: A technician will be an employee of the Contra Costa Sheriff's Office and have, at a minimum, the following education, experience, and training:

      1. A bachelor's degree in a natural science or a closely related field.

      2. Prior experience or training (in-house or external) in forensic DNA testing to include; procedures and tasks to be performed at the laboratory.
3. A competency test in the analytical techniques to be performed.

c. **Authorization:**

1. Upon successful completion of training and a competency test, a technician will be authorized to handle DNA extracts and products from casework at the direction of a qualified examiner for purposes of assisting with analytical techniques related to DNA analysis. This includes all equipment, software, procedures, reagents and supplies necessary to perform their job duties. The technician will be authorized to perform other assigned duties based on the scope of their training.

2. Technicians will not; interpret or draw conclusions on analytical results, serve as a reviewer, prepare final reports, or release information or results to any outside agency.

3. Technicians will have limited access to evidence storage and may need to testify to the scope of their duties.

4. **DNA Analysts QAS 5.4**

a. **Role:** A DNA analyst will perform DNA analysis on a range of evidentiary materials to the extent they have received training and competency testing, including evaluation and preparation of the evidence, interpretation of analytical results, preparation of reports and expert testimony. A DNA analyst may also conduct some of the Unit's quality control activities, such as performance checks, calibrations, and validation activities.

b. **Qualifications:** A DNA analyst must be an employee or contract employee of the Laboratory and have, at a minimum, the following education, experience, and training:

   1. A bachelor's degree in biology, chemistry or forensic science related area which includes; a minimum of nine cumulative, semester-equivalent hours credited in coursework in biochemistry, genetics and molecular biology (molecular genetics, recombinant DNA technology). The subject of biochemistry, genetics, or molecular biology must constitute an integral component of such credited coursework. Course work and/or training in statistics and population genetics as it applies to forensic DNA analysis is also required.

   2. Documented approval of coursework by the DNA Technical Leader, prior to commencing casework.

   3. Prior experience or a minimum of six months of forensic DNA laboratory experience to include; analysis on a range of samples typically encountered in forensic casework or training (in-house or external) in DNA analysis to include; hands-on training following laboratory procedures and analysis on a range of samples typically encountered in forensic casework.

   4. A competency test in the DNA analytical techniques and procedures used in the Laboratory, using a range of samples typically encountered in casework.

c. **Authorization:**

   1. Upon completion of training and competency testing, an examiner will be authorized to access evidence storage, use reagents and supplies necessary to perform casework, use all equipment, instrumentation and procedures they were trained to use, issue reports, give opinions and interpretations associated with the scope of DNA testing the examiner has been qualified to perform.

   2. The examiner is authorized to release results to the client agency, adhering to Division Policy, and provide expert testimony.

   3. Acknowledgement of completion of training and competency testing and authorization to conduct casework will be documented on the examiner's training log and an authorization will be written.

5. **Laboratory Support Personnel QAS 5.7**

a. **Role:** Laboratory Support Personnel are employees who perform laboratory duties exclusive of analytical techniques on forensic samples. These individuals can be responsible for performing activities such as quality control duties, instrument maintenance, validation studies/performance checks, ordering, and reagent preparation.

b. **Qualifications:** Laboratory Support Personnel will be employees of the Contra Costa Sheriff's Office. They will have at a minimum the following:

   1. Meet the degree requirements for a Sheriff's Specialist.

   2. Training on the procedures and tasks to be performed at the laboratory.
3. A competency test in the techniques to be performed.

c. **Authorization:** Upon successful completion of training and a competency test, laboratory support staff will be authorized to perform the tasks they were trained to perform within the unit.

6. **Contract Employees QAS 5.4**

   a. **Role:** An individual who is not an employee of the Contra Costa Sheriff's Office and who meets the requirements specified in the DNA Quality Assurance Standards on education, experience, and training as a DNA analyst, if providing DNA casework services, or an individual who is qualified to perform biological screening services. The contract employee must work in accordance with Division policy and procedures, as well as, the laboratory's quality system. If employed or seeking employment by another NDIS participating and/or vendor laboratory, the contract employee shall disclose this information and seek approval from the Technical Leader. The Technical Leader will review the employment for potential conflict of interest issues.

   b. **Qualifications:** A contract employee may perform biological screening, DNA analysis, or technical review. The contract employee must meet the same qualifications regarding education, experience, training, and competency testing as specified for a Biological Screener, DNA analyst, or Technical Reviewer.

   c. **Authorization:**

      1. Upon successful completion of training and a competency test, a contract employee will be authorized to conduct and technically review casework to the extent in which they are trained.

      2. Acknowledgement of completion of training, competency testing, and authorization to conduct casework will be documented on the individuals training log.

      3. The contract employee cannot serve as a Technical Leader or a CODIS Administrator, and is not counted as a full time employee for purposes of meeting the minimum staffing requirements for a DNA Laboratory.

7. **DNA Technical Leader QAS 5.2**

   a. **Roles and Responsibilities of the DNA Technical Leader:** The Technical Leader will work closely with the Unit Supervisor on quality issues and inform the CODIS Administrator of any quality issues that may affect CODIS, and be responsible for the following duties: QAS 5.2.3

      1. Oversee the technical operations of the DNA program
      2. Oversee Quality Assurance of the DNA program
      3. Evaluate and document the approval of all validations and methods, and to propose new or modified analytical procedures to be used by DNA analysts
      4. Review the academic transcripts and training records for newly qualified analysts and approve their qualifications prior to independent casework analysis and document such review.
      5. Approve the technical specifications of outsourcing agreements.
      6. Review internal and external DNA Audit documents and, if applicable, approve corrective action(s), and document such review.
      7. Review, on an annual basis, the DNA procedures and document such review
      8. Review and approve the training, quality assurance and proficiency testing programs
      9. Review requests by contract employees for employment by multiple NDIS participating and/or vendor laboratories and, if no potential conflict of interest exist, approve such requests.
      10. A newly appointed DNA Technical Leader will be responsible for the documented review of the validation studies and methodologies currently used by the DNA unit and the review of the educational requirements and training records of the currently qualified DNA analysts. QAS 5.2.5

   b. **Qualifications for DNA Technical Leader QAS 5.2.2:** The DNA Technical Leader must be a full time employee of the Laboratory and have, at a minimum, the following education, experience, and training: Completion of all requirements for a DNA Analyst.

      1. Minimum of three years of Forensic DNA laboratory experience as a qualified DNA analyst of forensic samples. This experience must have been obtained at a laboratory where forensic DNA testing was conducted for the identification and evaluation of biological evidence in criminal matters.

      2. Either A or B:

         A. A minimum of a Master's degree in biology, chemistry, or a forensic science-related area and successful completion of a minimum of 12 semester or equivalent credit hours from a combination of undergraduate and graduate course work covering the subject areas of biochemistry, genetics and molecular biology, and statistics or population genetics. This must include, at minimum, the following: QAS 5.2.1
The 12 semester or equivalent credit hours shall include at least one graduate level course of three or more equivalent credit hours.

The specific subject areas listed above must constitute an integral component of the course to qualify towards meeting the required 12 semester hours.

B. Possess a waiver obtained from the American Society of Crime Laboratory Directors.

3. The technical leader must have successfully completed the FBI sponsored auditor training course, or complete the training within one year of appointment.

4. The individual appointed as the DNA Technical Leader will be a full time employee of the Laboratory and may be selected from technical, supervisory, or management staff, depending on the staffing levels of the Division, the existing budget situation, and the needs of the Division.

c. **Authorization:** The Technical Leader shall be accessible to the Laboratory to provide onsite, telephone or electronic consultation as needed. **QAS 5.2.4.** The DNA Technical Leader has the same authorities as those listed for a DNA analyst and Technical Reviewer, such as conducting independent casework and assisting in the technical review of casework. The Technical Leader is authorized to assist in assigning and administering DNA proficiency tests and assist in technical problem solving of analytical methods. The DNA Technical Leader has the authority to initiate, suspend and resume DNA casework for the Biology Unit or an individual.

8. **Casework CODIS Administrator QAS 5.3**

a. See [BIO.3.CODIS.05](#) for the casework CODIS Administrator's role, qualifications and authorizations.

9. **Technical Reviewer of In-house Generated Data QAS 5.5/12.1.1**

a. **Role:** A technical reviewer evaluates reports, notes, data, quality controls, and other documents to ensure there is appropriate and sufficient data for the test results and conclusions drawn.

b. **Qualifications:** A technical reviewer is an employee or contract employee currently or previously qualified in the methodologies being reviewed. A technical reviewer typically is an experienced examiner, who has gained expertise through training and experience in the discipline or category of testing. Other requirements are as follows:

1. Technical reviewers are trained in the scope of technical review, prior to participating in the technical review of in-house generated data/results.

2. An employee, such as a contract employee, whose sole responsibility is to perform technical review will be proficiency tested for the role of technical reviewing. The proficiency testing will cover the same technology, platform and typing amplification test kits that are used to generate in-house data/results.

3. Qualified DNA analysts who undergo semi-annual proficiency testing and who also conduct technical reviews of in-house casework meet the "technical review proficiency testing requirement" through the successful completion of their proficiency tests.

c. **Authorization:** After technical review training, an employee will be authorized to perform technical review to the extent they received training. The technical reviewer cannot be the author of the report or of the contents of the technical case notes supporting the report.

10. **Technical Reviewer of Outsourced/Vendor Generated Data QAS 17**

a. The qualifications of the technical reviewer and the requirements of the technical review process of examinations and results generated by another laboratory is addressed in [BIO.5.QAQC.17](#).

11. **Administrative Reviewers QAS 12**

a. **Role:** An administrative reviewer will evaluate the report for concordance and accuracy of information with the supporting case notes, for consistency with laboratory and unit policies, and for format, content and grammar.

b. **Qualifications:** An administrative reviewer will be an employee of the laboratory and demonstrate knowledge and understanding of the Laboratory's administrative review process ([FSD.18](#)) and the Biology Unit's review process ([BIO.5.QAQC.12](#)). Biology Unit examiners will be given authorization to conduct administrative reviews by the Biology Unit Supervisor. An administrative reviewer is not required to be a current or former DNA analyst or biological screener, however having experience will provide an added measure of review for the casework. An examiner who has training and who has gained expertise through casework experience in the discipline or category of testing will typically be designated by the Supervisor to be an administrative reviewer.
c. **Authorization:** After administrative review training and individual will be authorized to perform administrative review. An administrative reviewer cannot be the author of the report or of the contents of the technical case notes supporting the report. An administrative reviewer may also be the technical reviewer of the case file. When this occurs, the administrative reviewer must meet the qualifications of a technical reviewer.

---

**B. Continuing Education  QAS 5.1.3**

1. Continuing education is an integral part of maintaining expertise in the field of Forensic Biology. Each member of the Biology Unit, which includes the DNA Technical Leader, CODIS Administrator, Biological Screeners, DNA Analysts, and DNA Technicians will stay abreast of developments and issues within the field of Forensic Biology. This requirement is considered a mutual responsibility of both the employee and the laboratory management.

2. As an aid in maintaining currency in the field of Forensic Biology, the Laboratory will afford each Biology Unit member at least one session of continuing education per calendar year, that will be a minimum of 8 hours. DNA analysts must have a minimum of 8 hours of continuing education on subject areas relevant to the developments in DNA typing. A session of continuing education is generally defined as a discreet unit of on-duty work time devoted to professional development in a relevant discipline among one or more of the following categories: **QAS 5.1.3.1**

---

3. **External Continuing Educational Categories:**

   a. University level coursework. This coursework may be for formal credit, continuing educational credit, or on an instructor-approved audited coursework basis.

   b. Professional development courses offered through an outside agency, professional organization, or vendor. Examples include, but are not limited to:

      1. Formal instruction courses hosted by outside agencies such as the California Criminalistics Institute (CCI) and the Federal Bureau of Investigation (FBI)
      2. Workshops conducted by professional organizations such as IAFS, AAFS, CAC, and similar professional organizations
      3. Formal training offered by vendors such as Applied Biosystems and Promega.

   c. Seminars, symposia, or related scientific forums designed to disseminate recent technical material in the field of Forensic Biology. Examples include, but are not limited to:

      1. Seminars hosted by forensic societies such as AAFS, CAC, and similar organizations
      2. Symposia such as the International Symposium on Human Identification.

   d. Study Group and User Group forums. Examples include, but are not limited to:

      1. CAC User Group meetings hosted at semi-annual seminars
      2. CODIS user group conferences
      3. Vendor user group meetings such as the Applied Biosystems Users Group
      4. CAC DNA Study Group sessions.

---

4. **Internal Continuing Education:**

   a. Biology unit members may also fulfill continuing educational requirements through documented training conducted within the Laboratory. Valid internal continuing education will consist at a minimum of a program which includes a course title, date of training, attendance list, curriculum vitae of instructors, and a record or the material covered in the training session. **QAS 5.1.3.1.1**

---

5. **Multimedia or Internet based Continuing Education:**

   a. Biology unit members may fulfill continuing education requirements through programs based on multimedia or internet delivery (i.e. webinars, online courses). Participation in such programs shall be documented as well as the amount of time required to complete the training. Use of these programs for continuing education shall be reviewed and approved by the DNA Technical Lead, if the program is to be used as continuing education in the field of DNA analysis. **QAS 5.1.3.1.3**

---

6. **Scientific Literature:**

   a. The Laboratory provides and maintains relevant materials such as current books, journals, and other applicable literature in the field of Forensic Biology; the Laboratory provides internet capabilities for accessing off site resources; and the Laboratory affords each employee with on-duty time to pursue and maintain currency in the field. **QAS 5.1.3.2**
b. As part of the continuing education program, scientific journal articles on relevant forensic biology issues are reviewed by staff and approved by the DNA technical leader. Literature review can be documented in the form of a Literature Circulation Form or in the Laboratory’s electronic document control system (PowerDMS).

7. Documentation and Retention

a. Individual records of continuing education may consist of a certificate, agenda/syllabus or travel documentation. The documents are maintained electronically in the examiner's training module in LIMS and may also be maintained as hard copies in the examiner's training binder. **QAS 5.1.3.1.2**

b. Each individual in the unit is to maintain and keep current their Statement of Qualifications which is administered through the Laboratory Information Management System (LIMS) training module. The Statement of Qualifications reflects an examiner's qualifications, training, skills and experience records. **QAS 5.1.4**

c. The DNA Technical Lead will maintain records of literature read/reviewed by active DNA analysts. **QAS 5.1.3**

d. Continuing education records are retained minimally for 10 years according to Division Manual policy "Control of Record" **FSD.44 QAS 3.2**

END OF DOCUMENT
From the time of receipt until relinquished back to the client agency, the integrity of evidence is controlled through the use of security, facility layout and design, handling practices, and procedural controls for monitoring.

Refer to BIO.5.QAQC.19 for evidence controls dealing with evidence handling practices and procedural controls for monitoring for DNA contamination.

**Facility Layout and Design Controls (QAS 6.1)**

The laboratory layout, as well as, segregated Biology Unit examination areas play a role in preventing the contamination of evidence. All examination functions throughout the laboratory are in areas separate from office/administrative areas to ensure staff’s safety and to prevent contamination.

1. An evidence item may be examined by more than one discipline in the laboratory. Each discipline has their own dedicated work spaces and are separated from one another in the laboratory.  
2. Biological evidence typically will progress through one or more of the designated work areas within the Biology Unit, such as through the biological screening area, DNA extraction and setup, and amplification.  
3. Each area is designed and equipped for the type of examination(s) or for the type of procedures that will be conducted in the particular work space area. The design is intended to meet specific examination requirements, as well as, to ensure casework efficiency and prevention of evidence contamination. (ISO/IEC:17025 Std 5.3.3)

The Biology Unit is organized and separated into the following examination areas: (QAS 6.1.2 & 6.1.3)

1. The main examination/screening areas are comprised of dedicated work stations that are individually equipped to conduct biological screenings and/or for preparing and handling specimens for DNA analysis.  
2. Additional isolated areas are available for instrumental examinations that require the use of specialized lighting or equipment, such as a microscope, an ALS or IR lighting. These work areas are separated from the DNA extraction areas, PCR setup areas, and the PCR room.  
3. DNA extraction is conducted in a designated area separate from screening and amplification areas. The extraction area is equipped with dedicated chemical hoods with pipettes and centrifuges for performing organic extractions and extraction robots that are fully enclosed for DNA extraction and recovery. The equipment and supplies for either organic extraction or robotic extraction are dedicated to the extraction work space. Concentration of DNA is conducted either with single use concentration devices, or in an evaporative centrifuge within the extraction area.  
4. The mastermix setup for qPCR and PCR is conducted manually in dedicated hoods or within an enclosed liquid handling robot. The equipment and supplies for manual and robotic qPCR and PCR set-up are dedicated to the work space area. PCR and qPCR setups are conducted within the same dedicated work space hoods, but the setups are conducted at different times.  
5. The PCR room is dedicated to the amplification and typing of DNA and is furnished with instrumentation, equipment, and supplies dedicated for this purpose. The PCR room is in an enclosed room that is physically separated from the other examination areas. All generated DNA product, equipment and supplies are maintained indefinitely in the PCR room until discarded.

**Security Controls (QAS 6.1)**

1. Access to the laboratory is controlled and limited to prevent access by unauthorized personnel. Security and controlled access areas in the laboratory are described in the Division Manual section on Security, FSD.32. (QAS 6.1.1.a & .b)  
2. Designated Biology areas have limited access to Biology staff, Supervisors, and Management via key card.  
3. Authorized FSD employees have access to the evidence storage rooms, including the incoming and outgoing freezers. In-progress Biology freezers are restricted to biology staff within the biology work area.  
4. The PCR room door(s) are kept closed at all times. The PCR room and the CODIS room are situated in designated Biology areas where access is limited to Biology staff, Supervisors, and Management. (QAS 6.1.3.a)  
5. The last employee to leave any of the dedicated Biology Unit areas is responsible for turning off the lights and ensuring the doors are closed upon leaving.

**Environmental Controls**
In addition to security and facility designs with dedicated examination areas, other evidence control measures are implemented to protect the integrity of the evidence and analyses conducted.

To ensure the evidence remains unaltered by improper environmental conditions, the laboratory is climate controlled and uses climate controlled equipment, such as refrigerators and freezers, and provides suitable lighting, energy, and noise reduction for the examination and equipment needed for the analysis of biological specimens. *(ISO/IEC:17025 5.3.1)*

1. Proper environmental temperatures are to be maintained during biological examinations and testing, for sample storage, and for proper function of instrumentation.

2. The proper evidence storage temperatures for refrigerators and freezers are dependent on the evidence, reagents and supplies that are maintained in each individual unit.
   a. The temperature conditions of refrigerators and freezers are monitored on a routine basis and the procedures for monitoring are described in the common laboratory equipment procedure, BIO.5.QAQC.24.

3. Temperature and environmental conditions required for particular technical or instrumental procedures are specified in the relevant technical procedures.
   a. To monitor the performance of analyses that might be affected by environmental factors, internal procedural controls are used to monitor the performance of the analysis. For example, the size standard can be used to monitor for fluctuations in the ambient temperature of the PCR room.

4. Unnecessary noises and distractions that affect an examiner’s concentration or draw the examiner’s attention away from their work are to be minimized and avoided, when possible. Examinations should be postponed if a laboratory activity has the potential to jeopardize the quality of the work product.

5. Examination will be stopped when environmental conditions jeopardize test results, such as poor lighting, temperature, risk of contamination, safety, and excess noise and distractions.

END OF DOCUMENT
I. The Biology Unit follows the Division's policies for evidence handling and itemization with the following additions and/or clarifications. All evidence will be handled and stored in a way that will minimize the possibility of loss, degradation, contamination, and deleterious change.

A. Evidence Receipt and Chain of Custody QAS 7.1.2
   1. The Biology Unit adheres to the Division Manual, FSD.35 for procedures addressing evidence receipt and chain of custody.

B. Conditions Requiring Work to be Halted
   1. If the Biology Unit begins an examination but finds abnormal conditions that impact the Unit's ability to complete the work, the customer will be contacted to resolve the situation. For example, when a package does not contain the item described on the request form or the package is labeled incorrectly.

C. Evidence Examination and Collection
   1. Each item of evidence submitted to the laboratory and created by the laboratory is assigned a unique LIMS submission number. An examiner uses the LIMS submission number(s) assigned to the Lab request to obtain the correct evidence from incoming storage. The condition of the packaging is inspected for proper seal to ensure the evidence has not been accessed, altered, compromised or potentially lost. Once opened, the content(s) are inventoried.
   2. Prior to evidence being permanently altered or consumed the evidence needs to be documented. See BIO.5.QAQC.21 for information regarding evidence documentation. Documentation may also include sketches or photographs.
   3. The evidence collection should first concentrate on evidence easily lost, such as hair and trace, and then to stains.
   4. Paper folds and Post-It notes may be used for the collection of trace evidence such as hairs and fibers.
   5. Collection should be done using the most direct but least intrusive method.
   6. Collection Procedures
      a. Cutting may be used for stains absorbed into a porous surface, such as clothing or bedding. For large items, such as carpets, bedding, upholstery, etc. it may be necessary to cut out the stained areas for later testing and preservation.
         i. Use a clean razor blade or scalpel to excise a portion of the stain (typically 0.5cm x 0.5cm), however larger cuttings may be taken.
      b. Swabbing is the preferred method when the stain is on a non-porous surface, such as condoms, glass, leather, metals, plastics, and various weapons. Swabbing may also be the preferred method if a direct cutting is likely to increase inhibitors in the sample, or when surface cells are the targeted evidence.
         i. Moisten a sterile cotton swab(s) using sterile water. Be sure not to saturate the swab completely.
         ii. Rub the wet swab(s) over the area of interest thoroughly, collecting and concentrating as much of the stain or touch DNA as possible.
         iii. Allow the swabs to thoroughly air-dry and package or take directly to DNA digestion.
         iv. If the stain is limited or the target evidence is touch DNA, use a single swab to completely collect and concentrate the sample. More than one swab can be used for larger surface areas or large stains.
7. **Wet Biological Evidence**: Typically this is when condoms containing liquid are submitted to the laboratory. Dry cotton swabs or cloth swatches should be used to collect all the liquid. Allow swabs/swatches to air-dry and package.

8. **Substrate Controls** can be obtained by taking a swab sample or cutting of a visually unstained area next to a stained area. These are typically collected when there is a potential that background DNA on an item will affect the ability to interpret the profile developed from the stain. The control and biological stain should be collected in the same manner. For example, if a swab is used to collect the stain, a swab should be used to collect from the control area. The same sized surface area or cutting should be taken as the stain when sampling.

9. All collected evidence must be itemized and must meet the criteria for chain of custody in FSD.35. See below for chain of custody criteria for DNA extracts.

D. **Consumption of Evidence QAS 7.3**

1. The Biology unit will make every effort to preserve a portion of the original evidence. Some items that typically contain trace levels of DNA (such as touch DNA swabs) may need to be consumed during testing. If evidence is to be consumed during testing a photograph of the item/swabs must be taken.

2. If evidence requires consumption and the case is filed with the DA's office, permission must be granted by the DA's office before examination commences. A defense representative or a defense expert may view and/or photograph the original evidence under the supervision of a biology unit staff member. All precautions to prevent contamination will be taken by all parties involved in the process.

3. If requested by the defense, a defense DNA expert may witness DNA testing (Sampling through STR amplification). The expert may take notes, however to minimize disruption to the analyst's concentration, photography or video taping of the testing will not be permitted. Experts are not permitted in the PCR room.

E. **Evidence vs Work Product QAS 7.1.1**

1. **Evidence**:
   a. Is any item or sample submitted as part of a criminal investigation and identified by the client agency as evidence.
   b. Is any sample split or directly removed from the original evidence (such as cuttings of stains, swabs, and trace evidence).

2. **Work product**:
   a. DNA extracts, PCR products, direct amplification digests, and anything generated during biological screening are considered work product.
   b. Remaining DNA extracts from evidence samples **will be returned** to the client agency. When a DNA extract is consumed the empty tube **may be discarded**.
   c. Processed substrates (swabs and cuttings) that have gone through cellular digestion are deemed to no longer contain biological material and **may be discarded**.
   d. Screening examination products may **be retained** for DNA analysis or **returned** to the client agency.
   e. Remaining PCR products, direct amplification digests, and internal lab QC samples **will be discarded**.
   f. Remaining DNA extracts from reference samples (where original reference material remains for re-testing) **may be returned or discarded**.

3. Biological screening products and DNA extracts are uniquely identified throughout processing. The unique identifier consists of the laboratory number and item number. The examiners initials and the date created will also be placed on the tube. Alternatively, tubes may be labeled with a unique barcode, created from the lab number and item number. The analyst will also initial and date the tubes as well.

4. For work products that cannot be directly labeled, such as those in 96-well plates, the specimen may be identified with a position number (i.e well A1, A2, etc). The lab number and item number of the evidence assigned to each well will be documented on a DNA worksheet.

5. DNA extracts are not evidence but will be itemized in LIMS as a child of the item it is being derived from.

F. **Evidence Packaging**

1. Paper bags and envelopes will be used for packaging of most biological material.

2. Wet or moist biological evidence must be dried prior to packaging.

3. Paper folds and Post-Its used to collect trace evidence such as hairs and fibers will be placed into evidence envelopes and properly sealed to prevent loss.
4. Evidence collected or generated during examinations, such as the collection of biological stains from the parent item, may be repackaged within the parent packaging or packaged separately from the parent.

5. Evidence collected and split from different evidence submissions or sub-items from the same case may be packaged together as long as each of the individual items/specimens are individually packaged and uniquely identified.

6. Biology work products may be placed back into an original package or a new package may be created to contain them. Where the biology work products are contained should be included in the case file.

7. A green disposition sticker advising the agency on how to store the evidence at their facility should be placed on the outer evidence packaging as well as a biohazard sticker.

G. **Evidence Storage QAS 7.1.4**

1. The Biology Unit adheres to the Division’s security measures and controlled access areas for evidence storage and work product in progress, FSD.32 and FSD.35. Additional Biology Unit specific facility lay out and design, security measures and access to the biological evidence are described in BIO.5.QAQC.06. Evidence not in the process of examination must be properly sealed.

2. In general, evidence containing any dried biological fluid should be stored frozen. Room temperature storage may be warranted for items when condensation may occur and alter the evidence.

3. Items too large to fit in the freezer may be retained in room temperature evidence storage or in secured and limited access areas. The evidence should be examined as soon as practical to minimize the amount of time left at room temperature.

4. Liquid biological evidence, such as liquid reference blood kits are stored refrigerated and examined as soon as possible. Liquid biological fluids, such as semen in a condom or in a container that may leak may be temporarily refrigerated (1 week) until examined or preserved for future examination. Fluids should be collected onto swabs or cloth and dried as soon as possible.

5. Abortion products may be stored temporarily refrigerated (1 week) or frozen.

H. **In Progress Evidence Storage QAS 7.1.3**

1. In progress evidence or samples may be stored in secured or limited access areas of the Biology Unit, such as in one of the locked examination rooms or in one of the Unit’s in-progress refrigerator/freezers.

2. For short absences (a few hours to overnight), it is not necessary to package and/or reseal evidence being examined when the examination occurs in the secured or limited access areas of the Biology Unit. The item may be left out overnight in a secured or limited access examination area, but must be protected and clearly identified/labeled, such as:
   a. Covered with clean butcher paper
   b. Labeled “Evidence” with examiner’s initials and date

3. When all biological evidence has been removed, or no biological material was found, items may be stored at room temperature under secured and limited access conditions until returned to the agency.

I. **Disposition of Evidence QAS 7.2, 7.3**

1. All evidence is typically returned to the agency or Sheriff’s Property Services, including evidence split from the original item and collected, such as cuttings of stains, collected swabs, and collected trace material.

2. The status of the original evidence will be documented in the case file as either; retained, returned, or consumed.

3. The location of DNA extracts and biology work product will be denoted in the case file.

4. If the evidence DNA extracts are consumed, it will be denoted in the case file.

5. The disposition of reference DNA extracts that are routinely discarded during the normal course of examinations will be noted in the examiner's case file.

6. Dried reference blood samples may be retained at the Laboratory for long term storage. This will be noted in the examiner’s case file.

7. Some of this information may be contained in the annex section of the report.

END OF DOCUMENT
I. The Biology unit will use validated methods that adhere to the DNA Quality Assurance Standards for Forensic DNA Laboratories and to the Forensic Services Division Manual.

II. Validations

1. The Biology Unit will adhere to the requirements of the Division Manual, Method Selection and Validation FSD.27, where applicable, when validation studies are performed.

2. Two types of validation are required to implement or modify scientific technical procedures for forensic analysis:

   1. **Developmental Validation**

      a. In general, developmental validation of novel forensic biology methods is not conducted in the Biology unit. Examiners will be familiar with publications, preferably peer-reviewed publications, supporting the underlying scientific principles. These publications will be maintained by the laboratory.

   2. **Internal Validation**

      a. An internal validation will be performed prior to implementing a new or significantly modified method, instrumentation that affects the test, and significant software (including software tools created in-house). Validation of software may occur simultaneously with the validation of the instrumentation that it is used with (for example, the validation of data collection software with the validation of a genetic analyzer).

      b. The appropriate sample number and the type of samples used in the internal validation studies should be sufficient to support and document the reliability and potential limitations of the method.

      c. All applicable internal validation studies, described below will be performed. Studies determined to be not applicable shall be addressed in the internal validation summaries.

         1. **Known and non-probative evidence samples or mock evidence samples:** Methods shall be evaluated and tested using known samples and non-probative evidence samples or mock case samples prepared from authentic cellular material(s). Mock evidence samples should be reflective of the type and quality expected to be encountered in casework (e.g., various substrates, various stain concentrations). Results from these studies should be compared to the previous results where possible to ensure concordance (i.e., demonstrate agreement between the results obtained compared to those using previous methods or published data). Observed discordance should be documented and where possible a reason given for the non-concordance.

         2. **Precision and Accuracy:** Precision and accuracy studies should address repeatability (i.e., evaluate results of the same instrument and/or operator) and/or reproducibility (i.e., evaluate results among different instruments and/or operators), when practicable.

         3. **Sensitivity and stochastic studies:** Sensitivity studies are used to determine the dynamic range, ideal target range, limit of detection, limit of quantification, heterozygote balance (e.g., peak height ratio) and the signal to noise ratio associated with the assay. Sensitivity studies should include a range of template DNA/cellular material that brackets the optimal quantity. Stochastic studies are used to evaluate excessive random effects (e.g., allele drop-out, peak height imbalance) generally resulting from low quantity and/or low quality samples. Where appropriate to the interpretation model utilized, these studies are used to determine the laboratory’s stochastic threshold.

         4. **Mixture studies:** Mixed DNA samples that are representative of those typically encountered in testing shall be evaluated. Forensic mixture studies should use known samples that represent the number of contributors and the range of general mixture types for which the procedure will be used in casework (e.g., mixture
proportions, template quantities) and should be used to develop interpretation guidelines.

5. **Contamination assessment:** The laboratory shall evaluate the detection of exogenous DNA (e.g., allele drop-in) originating from reagents, consumables, operator and/or laboratory environment using both controls and known samples. The contamination assessment should be used when developing quality control procedures and interpretation guidelines.

4. Analysis parameters, such as match criteria and guidelines for interpretation including guidelines for mixture interpretation will be based on the data compiled in the validation study.

5. The scope of the validation will be assessed by the Supervisor and/or the DNA Technical Leader. Internal validations will also be reviewed and approved by the Biology Unit Supervisor or DNA Technical Leader prior to implementation.

### III. Performance Verifications

1. A performance verification is a check of the reliability of a previously validated method, procedure, software, or equipment by demonstrating through objective evidence that the performance characteristics of the item have been met. Performance verifications are typically less extensive than validations.

2. Performance verifications are performed:

   1. When a new critical instrument of the same model and analysis software package is obtained. The performance check will entail a comparison of the new instrument (added or upgraded model) against a current or previous instrument using the same DNA controls or previously characterized DNA samples.

   2. When software is upgraded but the upgrade does not impact interpretation, the analytical process, or sizing algorithms. The performance verification may entail a comparison of the interpretation, analytical process, and sizing algorithms of current or previous validated software to the upgraded software.

   3. When software that conducts calculations or data transfers is created by the laboratory using a commercial software (for example, DNA Worksheets created in Excel). The software will be checked to ensure accuracy of the data transfers and calculations by comparing them against another calculation method.

   4. When a procedure is modified in such a way as to alter the validated steps, reagents, or critical instruments. The modified procedure must be evaluated by comparing the original procedure to the modified procedure using similar DNA samples.

### IV. Documentation

1. A Plan must be submitted prior to starting a validation or performance verification. The plan is documented on FSDF.20.

2. The scope of the validation/performance verification will be assessed by the Supervisor and/or the DNA Technical Leader. It will also be reviewed and approved by the Biology Unit Supervisor or DNA Technical Leader prior to implementation. This approval will be documented on FSDF.12.

3. Validation studies and performance verifications will be documented, summarized, and retained on the Biology Unit's network folder and will be accessible for all Biology Unit staff to review.

END OF DOCUMENT
I. The Biology Unit is committed to assuring the accuracy and reliability of the tests performed. Methods to monitor the validity of the results include the following:

A. Use of Reference Materials

1. Certified Reference Materials: The following certified reference materials are purchased from an externally traceable source with vendor certification:
   a. **PCR-Based DNA Profiling Standard.** This is a NIST SRM and is used to establish NIST traceable samples.
   b. **Human DNA Quantification Standard.** This is a NIST SRM used to conduct a calibration check of the DNA standard provided in the PowerQuant Quantification Kit.
   c. Storage and Handling
      i. All reference materials are handled wearing appropriate PPE to prevent contamination of the material. They are stored according to manufacturer specifications and are not used past the expiration date listed on the manufacturer’s certificate of analysis.

2. Other Reference Materials:
   a. **NIST Traceable Samples.** Known blood or other biological samples from known individuals are compared against the NIST SRM PCR-Based DNA Profiling Standard to generate internal reference materials. The reference materials may be dried biological stain swatches or swabs.
   b. **Promega Human Genomic DNA Standard.** This DNA standard is purchased from an external vendor and includes a certificate of analysis. The standard may be used to conduct a calibration check of the DNA standard provided in the PowerQuant Quantification Kit.
   c. **Storage and Handling:**
      i. Reference materials are handled and prepared wearing appropriate PPE to prevent contamination of the material. They are stored frozen or according to manufacturer specifications.

B. Annual Performance Check of DNA Procedures/Equipment QAS 9.5.5

1. A performance check using NIST or NIST traceable samples is conducted annually to ensure reliable and accurate results are obtained for each DNA procedure. These procedures include cellular digestion, robotic and organic extraction, quantification, amplification, and detection on the Genetic Analyzer and include the following equipment:
   a. Qiagen EZ-1 and EZ1 XL Robots
   b. Liquid Handling Robots
   c. Real Time PCR Instruments
   d. Thermal Cyclers
   e. Genetic Analyzers

2. Any new or modified procedure/instrument introduced into the DNA process is also checked using NIST or NIST traceable sample(s) prior to use with casework to verify its performance.

3. The procedure for the annual performance check of DNA procedures is maintained in the Biology Unit’s network folder.

C. Functional Checks of Measuring and Testing Equipment
1. Measuring and testing equipment is validated or performance checked prior to being placed in service and annual preventative maintenance or calibration is performed on instruments that have an affect on testing. See BIO.5.QAQC.10 for a list of instruments that undergo annual calibration and preventative maintenance.

D. Review of Reported Results
1. The Biology Unit annually conducts several reviews of reported results which include:
   a. An annual FBI Quality Assurance Audit (See BIO.5.QAQC.15)
   b. An annual internal audit
   c. The annual DNA Quality review conducted by the DNA Technical Lead (See BIO.5.QAQC.12)

E. Technical and Administrative Review
1. All casework conducted by the Biology Unit is technically and administratively reviewed (See BIO.5.QAQC.12)

F. Interlaboratory Comparisons
1. See FSD.23 and BIO.5.QAQC.13 for more information

G. Use of Standards and Controls for DNA Testing
1. The use of standards and controls are documented in each of the individual DNA procedures. See the individual procedures for additional use of each of the standards and controls.
2. Controls for DNA Extraction

   QAS 9.5.3 At least one reagent blank (negative control) is required to be associated with an extraction set. Generally two reagent blanks are associated with an extraction set and are used to monitor for DNA contamination.

   QAS 9.5.3.1 The reagent blank is extracted concurrently with the extraction set and is carried through the extraction, concentration, amplification, and the typing process as a check of all reagents used during processing.

   a. The reagent blank associated with a reference sample set is named RBR. The reagent blank(s) associated with an evidence set is named RB-1, RB-2, etc.
   b. Each fraction of a differential digest includes at least one reagent blank.
   c. If the digest buffer volume for a particular sample is doubled, the corresponding RBR or RB-1, RB-2, etc. must also contain double the volume of digest buffer.
   d. If several evidence samples are combined into a single extract, multiple reagent blanks must be similarly prepared and combined into a single extract.
   e. If multiple reagent blanks are extracted, at least one of the reagent blanks must be amplified and typed concurrently with the evidence. If more than one reagent blank is quantified, the sample with the highest signal, if any, is amplified. Reagent blanks are not required to be quantified, unless DNA analysis is terminated at the quantification stage.
   f. If samples are concentrated at any point, the corresponding reagent blank from the extraction set must also be concentrated to an equal (or lesser) volume to ensure the most sensitive volume conditions have been met.

   A positive extraction control (QC sample) monitors if the DNA procedures used worked properly. The QC sample is a DNA profile from a known source that is extracted and may be typed concurrently with the extraction set. QC samples are optional.

3. Controls and Standards for DNA Quantitation
   a. QAS 9.5.1 A set of quantitation standards are required in the quantification process and is used with the PowerQuant Kit. The standards are used to establish a calibration curve to estimate DNA concentration. The quantitation standards are calibration checked against a NIST SRM or equivalent reference material.
   b. A positive control (IPC) is integrated into the PowerQuant Quantification Kit's components and monitors for proper amplification.
   c. A negative template control (NTC) is required for PowerQuant reactions and contains master mix and amplification grade water. The negative control monitors for contamination in the quantitation reagents or
in the quantitation setup environment. See Human DNA Quantitation procedure BIO.2.DNA.06.

4. Controls for STR Amplification
   a. **QAS 9.5.2** Positive and negative amplification controls are **required** in the STR amplification process. The positive control is known human DNA that monitors if the amplification and typing process worked properly. The negative control monitors for DNA contamination in the PCR reagents or PCR setup environment.

   b. The controls must be amplified concurrently in the same instrument with the same kit primers as the samples. The correct DNA profile must be obtained from the known positive control and no DNA must be detected in the negative control in order to make DNA typing calls for the evidence samples. See Amplification procedure BIO.2.DNA.08.

   c. **QAS 9.5.3** At least one reagent blank control associated with each extraction set is **required** to be amplified. The reagent blank must be amplified using the same kit primers, instrument model, and concentration conditions as the sample(s) in the extraction set with the least amount of DNA.

5. Controls and Standards for Capillary Electrophoresis (CE)
   a. A CE reagent blank, consisting of formamide and sizing standard, is run with each CE plate. The purpose of this reagent blank is to detect contamination that might occur in the CE reagents or in the CE setup environment.

   b. **QAS 9.5.3.3** At least one reagent blank control associated with the evidence set is **required** to be typed on the same CE instrument model, at the same injection time, and under the most sensitive volume conditions as the associated extraction set.

   c. **QAS 9.5.4** An allelic ladder and an internal size standard are **required** for typing amplified DNA (STR) products. The allelic ladder must span the allelic size range of the STR typing kit used for amplification. Each amplified sample, evidence as well as all controls, must contain an internal size standard in order to perform typing. See procedures for Capillary Electrophoresis BIO.2.DNA.09 and Analysis of Short Tandem Repeats BIO.2.DNA.10.

H. Methods not used to monitor tests
    1. At this time the Biology unit does not use calibrated alternative instrumentation, control charts, intermediate checks on measuring equipment, replicate tests or calibrations using the same or different methods, verification of results, and testing of blind samples. The unit also does not retest retained items.

I. Documentation and Recording
    1. The data derived from the monitoring activities above are documented the following ways:
       a. Equipment logs, maintenance documents, and performance check documentation
       b. Reagent logs
       c. Level I and II corrective actions
       d. Annual reviews and audit documents

J. Monitoring
    1. The outcome of monitoring is reviewed, at minimum annually during internal audits and DNA QAS audits.

II. The Biology Unit maintains the following reference collections:
    A. The staff DNA profiles reference collection contains the DNA profiles of laboratory staff and other individuals involved with evidence handling. This reference collection is maintained to possibly help identify the source DNA in events of contamination. Each profile is assigned a unique CODIS code and is stored in the local CODIS database and in a spreadsheet on the Biology Unit's internal network drive that is only accessible to Biology Unit staff.

       1. The database is updated when new staff is hired. A buccal sample is collected from the individual and is typed by any available staff authorized or in training to perform DNA testing. The profile is then assigned a CODIS code and added to the local CODIS database by a CODIS administrator. The profile is also added to reference collection spreadsheet followed by a Supervisor check.

    B. The "CoCo Profiles" reference collection is a spreadsheet containing DNA profiles generated from cases within the Unit. This reference collection is maintained to help identify possible sources of DNA in contamination events. Each profile is assigned a unique laboratory request and item number. The spreadsheet is maintained on the Biology Unit's internal network drive and is accessible only to Biology Unit staff.

       1. The database is updated with any single source or clearly deduced profile generated in casework. The database is populated by the administrative reviewer during review.
I. The Biology Unit maintains an inventory of current equipment and software. Equipment that can influence test results are calibrated or subject to quality control checks to verify that their performance is suitable for the methods being used.

II. Equipment and Software

1. Equipment

   a. The Biology Unit uses equipment suitable for biological screening and DNA analysis. A list of equipment and significant software dedicated to the Biology Unit is maintained electronically. The list is updated when new equipment is acquired and equipment is permanently removed from service.

   b. Equipment in the inventory list is itemized by an identification number, manufacturer, model number, and item description. The Biology Unit designates the equipment identification number with an assigned letter and/or number.

   c. Equipment that provides unsatisfactory results will be removed from service and labeled with an "Out of Service" sign until the problem has been resolved and shown to perform correctly, or until the equipment has been permanently removed, if applicable.

   d. Copies of manufacturer user manuals for critical equipment are maintained in hard copy or electronically in the Biology Unit's network folder.

2. Software

   a. The Biology Unit uses software suitable for the methods employed. The Biology Unit maintains an electronic inventory of the the commercial software used, corresponding serial numbers, firmware version, and asset numbers of the computers associated with the software.

   b. Procedures that require the use of commercial critical software must identify the software and the version number. Software parameters are outlined in the procedure. Excel created software applications and any approved updates are listed in a log maintained by the unit. The Biology Unit uses the following critical software:

      1. HID Real Time PCR Analysis Software v1.2
      2. GeneMapper ID-X Software v1.5 and 3500 Data Collection Software v3 & 4
      3. STRStatFUSION and DOJ's KIn CALc
      4. STRmix v2.6

   c. Validation/Performance verification's of software will be documented through the QA Action process.

3. Equipment and software are safeguarded from adjustments that could invalidate test results by restricting electronic access to the Biology Unit staff and limiting its use to staff authorized to use the equipment and software. For GeneMapper ID-X and STRmix, parameters are set by an Administrator account and prevents users from changing certain parameters, Electronic worksheets are protected, when possible.

4. It is the responsibility of the Biology staff to ensure that equipment and software are set to the correct parameters before use. If for any reason, parameters are temporarily changed on shared equipment or software, it is the individual's responsibility to ensure the original parameters are restored after use.

III. Quality Control Checks

1. The schedule for equipment checks, calibration, and maintenance is found in BIO.5.QAQC.18.

2. Procedures for maintenance checks of equipment and software are found in Quality Assurance/Quality Control documents BIO.5.QAQC.24 through BIO.5.QAQC.27.

3. Annual Performance Checks of Critical Equipment

   a. The following critical equipment undergo annual calibration by an outside vendor:

      1. Digital Reference Thermometer, see BIO.5.QAQC.24
      2. Balances, see BIO.5.QAQC.24
      3. Thermal Cycler Temperature Verification Device, see BIO.5.QAQC.24
      4. Robotics (EZ-1 XL extraction robots and liquid handling robots (Nimbus and Versa)), see BIO.5.QAQC.25
      5. Capillary Electrophoresis Instruments/Genetic Analyzers, see BIO.5.QAQC.27
      6. Pipettes, see BIO.5.QAQC.25
      7. 7500 Real Time PCR Instruments, see BIO.5.QAQC.26

   b. Below are the required specifications for the calibration vendor and the equipment:
1. Equipment sent for calibration is packaged in a way to ensure that equipment from the pre and post-PCR rooms do not commingle and that they are protected from sustaining any damage during transport. All equipment sent out for calibration should be wiped down with a 10% bleach solution prior to being used in casework.

3. The following critical equipment is performance checked in-house using a vendor-calibrated temperature verification kit:
   a. Thermal Cyclers (ProFlex), see Bio.5.QAQC.26

4. The EZ-1 Robots are performance checked annually in-house by extracting at least two QC samples. The samples will be quantified to determine if an adequate amount of DNA was extracted.

5. **Annual Performance Checks of Non-Critical equipment**
   a. A performance check of the following non-critical equipment is performed annually either in-house or by an outside vendor:
      1. Heat blocks
      2. Refrigerator/freezers
      3. Hoods
      4. Microscopes

6. Intermediate checks of equipment may be performed by the Biology Unit. The procedures for intermediate checks are found in documents BIO.5.QAQC.24 through BIO.5.QAQC.27

### IV. Information on Services that Affect the Quality of Tests

1. **Selection**
   a. Vendors are selected for the calibration of Biology Unit equipment based on one or more of the following criteria:
      1. Calibration services are provided by an ISO17025 vendor
      2. Calibration services are provided by the manufacturer of the equipment
      3. The laboratory has a prior history of satisfactory service with the vendor
   b. Evaluations of services will be conducted by the Unit Supervisors. The following are used to evaluate vendor's:
      1. A vendor's scope document can be reviewed to ensure the calibration being requested is within the scope of the vendor
      2. A performance check using known DNA samples may be conducted after service
      3. Certificates previously issued by the vendor for services performed on a specific piece of equipment can be reviewed
   c. The unit will communicate to the vendor the requirements for the calibration/service being provided. This may be done through:
      1. A service contract being put in place
      2. A quote for services to be provided
      3. A letter outlining the requirements for service
d. Acceptance of services will be conducted by the Unit Supervisors through review of calibration paperwork and certificates provided by the calibration vendor. If a calibration or service is not adequate for the Unit's needs the vendor will be contacted and a subsequent service/calibration may have to be performed.

1. **Preventative Maintenance, Repair, Service, or Calibration**
   1. The following critical equipment is performance checked prior to use with casework, or after a repair, service, or calibration:
      a. EZ-1 and EZ-1 XL Robots
      b. Liquid Handling Robots (Nimbus and Versa)
      c. Thermal Cyclers (7500 & ProFlex)
      d. Genetic Analyzer
V. Maintenance/Service Records

1. Records of service, repair, and calibrations as well as any follow-up performance checks are maintained by the Biology Unit. Records are accessible for review to all Biology staff. Maintenance logs for previous years may be electronically archived.

2. In-house intermediate checks and routine maintenance are captured on Inspection Records Forms BIO.5.QAOCF.03 and BIO.5.QAOCF.04.
I. The Biology Unit provides a clear and accurate written test report to the customer. Generally, two types of reports are written in the Biology Unit: Laboratory Examination Reports and Laboratory Records of Notification Reports.

A. Types of Reports and Report Contents

1. Laboratory Examination Report: Documents the results, and conclusions of any technical work that has been performed, and interpretations and opinions associated with such testing. A laboratory examination report will be written with the following service types: Preliminary Screen, SAEK, Forensic Biology, DNA, and CODIS confirmation. The format of Laboratory Examination Reports are as follows:

   a. Header: The header includes a unique laboratory number assigned to the report, the agency’s case number, the name of the customer, issue date, and other relevant administrative information. See Division policy “Test Reports” for further requirements in the Header. **This information needs to match the information on the request form.**

   b. Purpose: (select "Observation" under result type in LIMS.) This section is optional and includes information on what testing or activity was performed if the service type does not properly describe the testing performed.

   c. Summary: (select "Summary" under result type in LIMS.) This section is optional, but should be included if there is a significant amount of information contained in the examination and results section.

   d. Examinations and Results: (select "Examination Results" under result type in LIMS). The content of the examination and results section will consist of the following, when applicable:

      1. An item number and description of the examined evidence will be reported.
      2. Any evidence not examined will also be reported.
      3. Relevant or significant observations about the evidence.
      4. Category of testing performed, such as testing for blood, semen, saliva, or DNA.
      5. Screening tests performed and results and DNA results for each evidence item examined.
      6. For DNA testing the following information will be included in the results and conclusions section:

          1. If there is an insufficient amount of DNA detected at quantification and samples will not be taken forward for amplification
          2. If a DNA profile was generated
          3. Is the profile single source or a mixture
          4. If a mixture, what is the minimum number of contributors to the mixture or the assumed number of contributors.
          5. Any assumptions used in the interpretation
          6. If any major/minor contributors were determined (for binary interpretation)
          7. All DNA inclusions and exclusions

      7. A conclusion statement will be reported for each item of evidence that was tested and the basis for all conclusions will be communicated in the report. Reasons for an inconclusive result or limitations to offering a conclusion will be explained. Examples include, data is too low level or there are too many contributors to the mixture.

      8. If applicable, a statistical statement is provided with all probative DNA inclusions to express the strength of the inclusion. A qualitative statement is reported for non-probative inclusions (for example, victim's profile generated from the victim's vaginal swab).

      9. Definitions specific to the testing or examinations performed, if not common knowledge or contained in the annex.
10. Results obtained by a vendor laboratory during outsourcing, if included in a report, must be clearly identified. The address of the vendor laboratory where the testing was performed will be captured in the case notes.

e. CODIS Profile: If applicable, the report will inform the client of any DNA profile that was entered into CODIS. If a profile is to be searched only at the state level it will be documented here.

f. Recommendations: A statement will be provided in the report when the client agency needs to be given further guidance, such as recommending DNA testing, when a different testing method is needed such as YSTR testing, or when a reference sample is needed for comparison.

g. Evidence Submitted: (This will populate automatically for evidence related to the request). The evidence section includes a list of either the evidence submitted under the request. The evidence descriptions should include from whom or where the evidence originated, such as from the victim, suspect, or the crime scene. The other ID field should be populated with the agency's item number, if included on the request form.

h. Disposition: (select "Disposition" under result type in LIMS). All examination reports will contain a disposition reflecting:

1. A description that denotes the status of the original evidence (retained, returned or consumed), as well as any generated/derived secondary evidence or DNA extracts (swabs, cuttings, and DNA extracts and screening products). Some of this information may be captured in the annex.

2. The retention of digital images, if applicable

i. Signature Lines and Date: Includes at a minimum:

1. Name, title, date, and signature of the analyst authorizing and accepting responsibility for the contents of the report.
2. Name, title, date, and signature of technical reviewer (if applicable).
3. Name, title, date, and signature of administrative reviewer. This is also the date that the report is issued.

j. Annex: May include depending on the service type:

1. A statement about the DNA technology and typing kit used for testing.

2. Definitions related to testing.

3. A statement regarding the scope of CODIS searches (unless only searched at the state level), how long profiles will be searched, and the circumstances under which a sample will be removed.

4. A statement regarding the report containing the opinions and interpretations of the analyst.

5. Additional compliance statements.

k. Page numbering: Page number, laboratory request number, and name of analyst on each page of report.

2. SAEK Examination Report Layout Most of the report will be automatically generated from the case notes. There are several sections that have to be added manually. They should be added by selecting “Edit Findings” Under the request number right click and select “Add Result”.

a. Purpose: (if applicable)

1. select “Observation” under Result Type.

2. Type in the purpose of your testing in the narrative section

b. Evidence

1. This is automatically populated from LIMS

c. Examination Results and Conclusions

1. Overall Bio Screen Comments

   1. Select “Bio Screen” under Result Type

   2. Type in general comments about the type of testing performed here
2. Individual item Results
   d. Items not Examined
      1. This is automatically populated
      2. All items with no screening notes added in LIMS will be added here

e. Overall Examination Results/Conclusions
   1. Select “Examination Results” under Result Type
   2. Type in any overall examination results and conclusions, comments here

f. Items to be forwarded for DNA Analysis
   1. This will automatically be populated with the items that have the “DNA Analysis” box selected in the case notes.

g. Disposition
   1. This will automatically populate from the disposition added in the notes

3. Report of Laboratory Notification: Notifies the client agency about an activity or a service provided by the Biology Unit as it relates to the client agency's case. These activities do not include evidence examination or testing. A notification report will be written for the following service types: CODIS notification, Discovery Requests, and Liquid Blood Preparation.

B. Personnel Issuing Reports

1. Reports are typically generated by the examiner who performed the work.

2. An examiner may be the author of a report as long as they are competent in the discipline or category of testing performed. The author may be the examiner who conducted, observed, or directed the testing, or has evaluated the observations, testing performed, and/or the technical data generated by another examiner.

3. If a circumstance arises that prohibits an examiner from issuing the report another qualified examiner may write the report. The examination notes will reflect the original examiner(s) responsible for the testing results. The examiner taking responsibility for the results and authoring the report will document their review of the case notes on the assignment notification page and will include the date(s) of review, and the pages reviewed and relied upon for the report.

4. An examiner testifying to the results generated by another examiner will review all of the original analyst’s notes and document the review of those notes on the assignment notification page. The documentation will include the name of the analyst testifying, date(s) of review of the case notes, and the pages reviewed for testimony.

C. Review of Reports

1. All Examination reports will undergo a technical, as well as an administrative review.

2. Laboratory Records of Notification Reports will undergo an administrative review. Additionally, for CODIS and DANY Grant Hit notifications the administrative reviewer's milestone in LIMS documents completion of both technical and administrative review.

D. Maintenance and Retention of Reports

1. Once administratively reviewed, the report and supporting case notes are transferred to the clerical area for filing into the case file. Clerical staff is responsible for the filing and maintenance of the case files.

2. Recently filed reports are retained at the laboratory for several years. Older reports may be stored off-site or archived according to Division Manual policy “Control of Records” FSD.44.

E. Access and Release of Reports, DNA Records, and DNA Databases

1. Access to Biology Unit reports is in accordance with the Division Manual policy “Control of Records”.

2. Reports are released and distributed according to Division Manual policy “Test Reports”.

3. Reports containing “DNA records” are similarly released according to Division Manual policy “Test Reports”. Release of DNA records in the Laboratory's CODIS database, however, is further restricted by State and Federal Law. See
4. **Reports:**

a. Reports containing DNA records may be released to the primary law enforcement agency, the District Attorney’s Office for judicial proceedings or to defense counsel for criminal defense purposes. Access and release of DNA records is limited to those DNA samples, exemplar samples, and analyses that were performed in connection with the defendant’s case. The defendant is not entitled access to other DNA records, samples, or other DNA analyses that are not associated with his/her case, under the provisions of the DNA Act.

b. When a positive association occurs as a result of a CODIS database search, a "CODIS Hit" Laboratory Notification Report will be written.

c. In the event that there is a CODIS hit and a reference sample is submitted for confirmation, a CODIS confirmation examination report will be written and typically will be a sub-request to the CODIS Hit request. A report will also be written if a profile is being removed from CODIS by the Laboratory.

5. **DNA Records:**

a. A DNA profile is considered a DNA record.

b. Access and release of reports containing DNA records is similar and in accordance with normal laboratory practices for the access and release of records.

6. **DNA Databases:** The laboratory's CODIS database is composed of electronic DNA records generated from evidence samples. When a DNA profile is eligible for searching in CODIS, the evidence profile becomes a DNA record in the CODIS database.

a. Physical access to DNA records in the Laboratory's CODIS database is limited to the CODIS Administrator and CODIS users.

b. Release of DNA records in the CODIS database is prohibited and allowed only according to Federal and State law. See CODIS Manual “Reporting and Disclosure of Matches” (BIO.3.CODIS.10).

c. The Biology Unit maintains an internal DNA database for quality control purposes. Access to the QC database is limited to the Biology Unit staff. The database contains profiles and information from other cases, as well as, quality control samples and laboratory staff profiles. Consequently, the QC database will not be released to any external entity for reasons of confidentiality.

END OF DOCUMENT
I. The Biology Unit conducts technical and administrative reviews for examinations and test results generated at the laboratory in accordance with policies set forth in the Division Manual on Technical Review (FSD.17) and Administrative Review (FSD.18).

II. Technical Review

A. Requirements

1. All Laboratory Examination Reports undergo Technical Review.

2. CODIS notifications will undergo a Technical Review. The administrative reviewer's milestone in LIMS documents the completion of both technical and administrative review.

3. All examination notes and technical reports which include technical data such as testing results, interpretations and/or conclusion statements from biological screening and DNA testing require a technical review.

4. Written or verbal results are not released to an outside agency prior to technical review. A technical review may be streamlined to a particular part or area of the case file in order to expedite the release of results. The specific data or area(s) in the case file that were reviewed will be captured with the date and initials of the reviewer. Release of verbal results are to be documented in the case file.

5. Prior to upload into CODIS, the examination notes and supporting data must be technically reviewed. The review includes verification that the correct DNA type was obtained, the case and profile is eligible for upload, and that the appropriate specimen category has been chosen. This verification is documented in the case notes on the data summary sheet which serves as a summary table of the DNA results. The procedure for verification and resolution of database matches is described in the CODIS Procedures Manual (BIO.3.CODIS.09).

6. For expedited cases, where it is imperative that the profile is entered into CODIS in a timely manner, the technical review can be concentrated on the relevant testing, data, and quality controls specifically related to the development of the CODIS profile. Those elements or pages in the case file that are technically reviewed will be captured in the case notes by initialing and dating the areas that were technically reviewed.

7. Review of data generated by an outside/vendor laboratory is governed by Standard 17 of the DNA Quality Assurance Standards and is discussed under the Biology Unit Outsourcing procedure BIO.5.QAQC.17.

B. Personnel Conducting Technical Review

1. Technical reviews are conducted by individuals that meet the qualifications listed in the Biology Unit's Personnel policy (BIO.5.QAQC.05).

2. A technical review cannot be conducted by the individual that performed the work or the author of the examination report.

C. Procedure

1. When the analyst has determined the case note packet to be complete, the examiner will sign the Technical/Administrative Review Checklist as "draft complete". The examiner will then turn the completed case note packet and report over to a technical reviewer or place it into the technical review bin. A technical reviewer may be assigned to the case by the Unit Supervisor or a qualified technical reviewer may assign themselves to the task.

2. The reviewer will address the elements of the technical review as documented on the Technical/Administrative Checklist Review Checklist(s). Documentation and the scope of the technical review is captured on the checklist and retained as part of the case notes. The below technical review checklists are used, as applicable to the type of analysis conducted. The elements to be addressed during the review of CODIS notification reports are listed in BIO.3.CODIS.10. CODIS notifications do not require the "Technical and Administrative Review" checklist.

D. 1. Technical and Administrative Review BIO.1.BIOF.02
    STRmix DNA Data Technical Review BIO.1.BIOF.06
DNA Data Technical Review_ BIO.1.BIOF.06.01
Vendor DNA Technical Review_ BIO.1.BIOF.03

E. The technical reviewer will document any observations, data, or test results that are rejected and why on the "Technical and Administrative Review Checklist". If corrections are needed, the case file is returned to the analyst to make any changes that might be needed.

F. Disagreements between the analyst and technical reviewer must be resolved prior to issuing a final interpretation and report. Resolution of disputes between analysts and reviewers will follow the Division Manual policy on Technical Review (FSD.17)

G. When technical review of the entire note packet is complete, the reviewer signs and dates the "Technical and Administrative Review Checklist" signifying concurrence with the examiner's testing and conclusions. The completion of the review is also electronically captured in LIMS.

H. Corrections

1. Corrections made to the notes, may be corrected by hand or electronically. Handwritten corrections are captured with the analyst's initials next to the corrected text. The corrected text may include an insertion, or a deletion with a single line strikeout.

2. Corrections made to notes after the case notes have been marked "draft complete", may be corrected by hand or electronically. When corrected by hand, the corrected text will be denoted with the date and initials of the analyst making the change. If corrected electronically a single line is drawn diagonally across the page being replaced, as well as the date, analyst initials, and the reason the page is being replaced. The replaced pages are retained in the case notes, typically at the end.

I. Scope of Technical Review

1. Technical review of examination reports will entail evaluating all criteria listed on the Technical and Administrative Review Checklist (BIO.1.BIOF.02) as well as the criteria listed on the DNA Data Technical Review sheet (BIO.1.BIOF.06.01) for all cases involving DNA analysis.

III. Administrative Review

A. An administrative review is an evaluation of the report and the supporting notes for concordance and accuracy of information, for consistency with laboratory and unit policies, and for format, content, and grammar.

B. Requirements

1. All reports and case packets will undergo administrative review.

2. Administrative review must occur prior to releasing a test report to an outside agency.

3. Administrative review cannot be conducted by the author of the test report.

C. Personnel Conducting Administrative Review

1. Administrative reviews are conducted by authorized individuals.

2. Administrative review of Biology Unit cases will be conducted by the Unit Supervisor, or another Supervisor, or another authorized individual.

3. Additional members of the Biology Unit may conduct reviews upon authorization by the Unit Supervisors.

4. Administrative and technical reviews may be conducted by the same individual as long as the individual meets the qualifications of a technical reviewer (see BIO.5.QAQC.05 ) and is authorized by the Supervisor to conduct administrative review.

D. Procedure

1. Case files ready for administrative review are forwarded to an approved reviewer or placed in the administrative review bin.

2. The administrative reviewer will follow, at a minimum, the scope of review as outlined in Division Policy FSD.18, and additionally the elements of the administrative review as outlined in the Technical/Administrative review checklist.

3. Documentation and the scope of the administrative review is captured on the checklist (only for examination requests) and is retained as part of the case notes or case record. QAS 12.3.3

4. If corrections are needed, the case file is returned to the examiner. See corrections under technical review for information on how to document corrections during administrative review.
5. For Laboratory examination requests, when the administrative review is complete, the reviewer signs the "Technical and Administrative Review Checklist" (this includes date and scope of pages reviewed). There is no review checklist for Laboratory notification requests. The reviewer will mark the case request in LIMS as administratively reviewed. The signature of the administrative reviewer on the laboratory report signifies completion and approval for release of the report and the supporting case notes.

E. Administrative Review Guidelines

1. Notes
   a. Verify Lab request #, analyst initials, page # on all pages
   b. Verify total # of pages on first and last page
   c. Verify all corrections recorded appropriately per FSD.42. Verify that all changes made after draft complete are dated and initialed.
   d. Verify technical review of the case notes is documented with the reviewer's signature, date, and pages reviewed on the appropriate pages, if applicable.
   e. Verify the information on the CODIS Specimen Detail Report is correct.

2. Report
   a. Header information is correct and concordant with Evidence Request Form.
   b. Reviewer concurs with the report language (spelling, grammar, transcription).
   c. Report follows appropriate format per BIO.5.OAQC.11
   d. Signature, date, and title of analyst and technical reviewer, if applicable, is present.

3. Other
   a. Activities are added in LIMS
   b. LIMS Data fields are completed
   c. DNA QC database updated
   d. GeneMapper IDX project is exported.
   e. DNA request is generated, if applicable.
   f. CODIS administrators are notified of a change in source ID
   g. Information for sexual assault DNA requests are added to the SAFE-T database.

IV. Annual Quality Review

A. The Quality System, as it pertains to DNA, is reviewed annually under the oversight of the DNA Technical Leader. The annual quality review includes an assessment of the following:

   1. Review of any audits/assessments conducted and any findings as the result of the audits. Including any internal audits, DNA Quality Assurance audits and external assessments.
   2. Review of technical manuals used for DNA analysis, including the DNA Analytical Procedures, Quality Assurance/Quality Control Manual and DNA Training Manual.
   3. Review of validations, performance checks, updates to procedures and requests for changes in procedures.
   4. Review of facilities.
   5. Review of equipment, including any new critical equipment purchased and critical equipment retired within the year.
   6. Periodic review of critical software for suitability and compliance with requirements, per FSD.34.
   7. Review of personnel, including any new analysts or new trainees and the status of analysts' proficiency tests, court critiques and continuing education for the year.
   8. Review of CODIS users.
   9. Review of any level two corrective actions regarding DNA analysis from within the year.
   10. Review court testimony is in accordance with the Division's Court Testimony Monitoring Policy (FSD.26).
   11. Changes to the volume or type of DNA work being performed.
   12. Recommendations for improvement/future projects.

B. The Annual Quality Review is documented in a memo or other equivalent form of interoffice communication and is retained by the Biology Unit. DNA quality reviews are retained for 10 years.

V. Technical Review of Testimony

A. All analyst's will have their testimony technically reviewed at least once per year, in each discipline they conduct testing (when applicable).
B. The technical review must be conducted by an individual competent in the testing the testimony is being given on.
C. Technical review of testimony is recorded on the Court Critique Form.
D. Retention of court testimony reviews is 10 years.

END OF DOCUMENT
I. All staff regardless of prior training and experience will undergo a competency test prior to being authorized to perform work in the Biology unit.

A. Purpose

1. The purpose of a competency test is to demonstrate the individual's knowledge and understanding, skill set in conducting tests, and ability to convey results and/or conclusions.

B. Scope of Testing

1. The scope of the competency test will be tailored to the individual's job duties and to the extent they will do casework.

2. The competency test may be administered in a modular format allowing the examiner to conduct casework in the area of competency.

3. A due date will be assigned in LIMS for all competency tests.

4. The criteria for successful completion of the competency test will be given to the trainee prior to the competency test being taken.

5. Previously used proficiency tests can be used but the identity of the test must be completely unknown to the trainee and the lab must have previously obtained the correct results. The expected results from internally created competency tests must be known to the individual creating the test prior to issuing the test.

6. Elements of a Competency Test

   a. A competency test will consist of hands-on practical test sets consisting of unknown biological samples.

   b. Completion of a written and/or oral examination to assess the individual's knowledge of the discipline and the methods and testing procedures.

   c. If the examiner's job responsibility entails writing laboratory examination reports, the examiner's competency test will also include a written report to demonstrate the examiner's ability to properly convey results and/or conclusions.

   d. Mock testimony.

C. Competency Documentation and Authorization

1. The Unit Supervisor's signature on the examiner's training log, will signify approval of the examiner's training and successful completion of the competency test. The DNA Technical Lead's signature will additionally be required for approval on the DNA training log. The approval will signify authorization for the examiner to conduct work to the scope of their training and competency.

2. Upon authorization, the individual is authorized to use all equipment, instrumentation and procedures as well as perform validations to the extent they received training and were competency tested.

3. If the examiner was competency tested in the area of report writing, the examiner is additionally considered to be authorized to issue reports and give opinions and interpretations in the area(s) for which training and competency has been documented.
4. Documentation and approval of the examiner's competency test will be maintained in the laboratory's Information Management System (LIMS), according to procedures detailed in QA.10.
   a. The Unit Supervisor and/or DNA Technical Lead will review the competency test and will be document the review on the Proficiency/Competency Test Data Summary Form.
   b. The signature of the tested individual, the DNA Technical Leader/Unit Supervisor and QA Coordinator on the Proficiency/Competency Test Data Form signifies notification of the test results to these individuals and approval of the competency test.

5. The examiner will enter into the proficiency test cycle within six months from the casework authorization date for a DNA analyst/technician and within 1 year for a biology screener.

II. All Biological Screeners will complete at least one proficiency test per year and all DNA analyst's/technician's will complete at least two external proficiency tests per year. Additionally, each analyst must be tested at least once during the five year accreditation cycle in each category of testing in which they have performed casework during that period.

A. Purpose

1. Proficiency testing is an element of the Biology Unit's quality assurance program. Proficiency testing is a means of monitoring the test methods and processes used in Biology, such as reagents, instrumentation, and procedures, as well as the methods and processes used by the examiner. The proficiency test is to be completed by the examiner similar to casework which includes a technical and administrative review.

B. Schedule of Testing

1. The Unit Supervisors maintain a schedule of proficiency testing for all Biology unit staff. The manufacturer's due date is routinely used to track and schedule Biology unit proficiency tests.

2. Each analyst, technical reviewer, technician, will undergo two external proficiency tests per year, in each technology (containing the CODIS core loci) that they perform casework testing, and to the full extent in which they participate in casework. The first test will be given in the first six months of the year and the second in the last six months of the year, where the interval between the two proficiency tests is no less than four months and no more than eight months.

3. The team approach (DNA analyst/DNA technician) currently being used for processing casework samples may be used during proficiency testing. A DNA analyst must however perform all DNA methods and platforms that they are qualified in at least once per year.

4. DNA analysts/technicians who become qualified in an additional method, technology, or platform will be proficiency tested on their new qualification in the next scheduled proficiency test.

5. Dedicated biological screeners will undergo external proficiency testing, at least once in the calendar year, in the areas for which they are qualified to conduct casework. For examiners qualified in screening and DNA analysis, a DNA proficiency that includes reporting biological screening and DNA will be conducted at least once in a five year cycle.

6. A newly qualified biological fluid examiner will enter the proficiency testing program within 1 year following their qualification to conduct casework.

7. A newly qualified DNA analyst/technician will enter the external proficiency testing program within six months of the date of their qualification. (QAS 13.1.2) Between the first proficiency and the second, the new examiner will cover all methods and technologies in which the examiner is qualified to conduct casework.

8. An examiner who does not conduct DNA casework but who's sole role is to perform DNA technical review will be proficiency tested in the DNA technical review process by reviewing two external proficiency tests per year to the full extent in which they are qualified to conduct technical review. The technical reviewer must currently be or have previously been qualified in the methodology that the review encompasses.

C. Scope of Proficiency Testing:

1. All external proficiency tests conducted in the Biology Unit are from an approved external proficiency test provider, such as Collaborative Testing Services (CTS) that is accredited to ISO/IEC 17043 by an accreditation body that is a signatory to the APLAC MRA or IAAC MLA and has the applicable proficiency tests on its scope of accreditation.
2. The results must be submitted to the proficiency test provider in order to be included in the provider's published external summary report.

3. **Additional DNA Requirements:**

   a. DNA analysts will attempt typing of all CODIS core loci for each technology in which the analyst is qualified, for both DNA proficiency tests in the year. This typing applies to each sample included in the proficiency test packet/set unless the sample does not meet the technical requirements of the technology (e.g. Y-STR's in the absence of male DNA.) **QAS 13.1.5**

   b. DNA casework examiners will be proficiency tested at least once a year in each of the manual and automated methods. **QAS 13.1.1**

D. **Documenting Proficiency Tests:**

   1. The following proficiency case records are documented and maintained electronically in LIMS, according to LIMS Proficiency Testing Procedures **(QA.10)**, as well as, a hard copy is placed in the laboratory's proficiency test file **(QAS 13.1.6):**

      a. The analyst's case notes and data supporting the conclusions. **QAS 13.1.6.4**

      b. The analyst's laboratory report.

      c. The proficiency test results and conclusions recorded on the test provider's data sheets. **QAS 13.1.6.5**

      d. The test provider's report of the intended and/or compiled (consensus) results.

      e. The Proficiency/Competency Test Data Summary Form which records the following:

         1. The LIMS laboratory (case file) number.

         2. Proficiency test number or test-set identifier. **QAS 13.1.6.1**

         3. Identity of the test provider (i.e. CTS and CAP)

         4. Test Provider's/Manufacturer's due date.

         5. Identity of the examiner. **QAS 13.1.6.2**

         6. Date assigned and completion date. **QAS 13.1.6.3**

         7. Any corrective action taken. **QAS 13.1.6.7**

         8. Satisfactory or Unsatisfactory completion of the proficiency test. **QAS 13.1.7.4**

E. **Evaluation of Proficiency Results**

   1. **Biological Screening**

      a. Biology screening test results are assessed against the consensus of reporting laboratories. For a satisfactory grade, no analytical errors or wrong conclusion can be reported to the test provider.

      b. Reported inconclusive or uninterpretable results should be consistent with the Biology Unit's interpretation guidelines and will be reviewed by the Biology Unit Supervisor.

   2. **DNA Testing/Analysis**

      a. DNA proficiency test results are assessed against the consensus of reporting laboratories. For a satisfactory grade, no analytical errors can be observed in the typing data of the DNA profile and all reported inclusions/exclusions must be correct. **QAS 13.1.7.4**

         1. If unsatisfactory, a corrective action will be implemented and the discrepancy and/or root cause will be documented. **QAS 13.1.6.6**

      b. Reported inconclusive or uninterpretable results should be consistent with Biology Unit's interpretation guidelines and will be reviewed by the DNA Technical Leader. **QAS 13.1.7.2**

      c. The Proficiency Test Data Summary Report form documents evaluation of the following for DNA proficiency testing **QAS 13.1.7.1:**

         1. All reported inclusions and exclusions are correct.

         2. All reported genotypes are correct according to the consensus results or according to the Biology Unit's interpretation guidelines.

         3. Inconclusive or uninterpretable results were reported according to the Biology Unit interpretation guidelines and were reviewed by the DNA Technical Leader.
d. Proficiency results may be verified by another qualified examiner or the Unit Supervisors. This verification will be documented in LIMS.

e. The Unit Supervisor and/or DNA Technical Lead will review the proficiency test with the examiner and will be documented on the Proficiency/Competency Test Data Summary Form.

f. The signature of the tested examiner, the DNA Technical Leader/Unit Supervisor and QA Coordinator on the Proficiency/Competency Test Data Form signifies notification of the test results to these individuals and approval of the proficiency test. **QAS 13.1.8 and 13.1.9.**

3. **Corrective Actions:**

a. A discrepancy or analytical error reported to the test provider will require a documented corrective action. The corrective action is documented according to the Quality Assurance Action Policy **FSD.16** and procedure **QA.18, QAS 13.1.7.3**

b. At a minimum, corrective actions involving DNA proficiency testing, the DNA Technical Leader will review, and approve the corrective action(s) prior to implementation. **(QAS 14.2)** The approval of the DNA Technical Lead is documented on the Quality Action Request.

c. The DNA Technical Lead will inform the CODIS Administrator at the time of initiating a non-administrative corrective action (Quality Assurance Action Request) citing the nature of the discrepancy in the proficiency test. **QAS 13.1.9.a**

4. **Documentation and Retention:**

a. Proficiency tests are documented according to the LIMS Proficiency Testing Procedure **QA.10** and will be retained by the Laboratory according to Control of Records Policy **FSD.44**. This retention is minimally 10 years. **QAS 3.2**

END OF DOCUMENT
I. Introduction

A. Corrective actions and preventative actions are part of improving and maintaining the Unit's overall quality management system. The Unit's corrective action policy adheres to the FSD policy (FSD.15), ANAB requirements, and the requirements set forth in the DNA Quality Assurance Standards for Forensic DNA Laboratories (QAS 14).

II. Authorities and Responsibilities

A. The Unit Supervisor(s) has the discretion to determine the appropriate corrective action(s) to be taken.

B. The DNA Technical Lead oversees the quality assurance of the DNA program, thus has the authority to suspend and resume technical operations of the unit or for an individual, if deemed necessary. (QAS 5.2.3) The corrective action plan requires the approval of the technical leader before implementation.

C. The CODIS administrator must be notified when the nonconformity impacts DNA records entered into CODIS. If necessary, the CODIS administrator may terminate an analyst’s or laboratory’s participation in CODIS until the reliability and security of the computer data can be assured in the event an issue with the data is identified.

III. Levels of Non-Conforming Work and the Corrective Actions

A. Quality Action Correction (QAC Level 3): Action taken to correct a non-conformity when the significance of the non-conforming work is minimal. The correction is readily apparent and can be made quickly. The action will be taken immediately, often by the person observing the non-conformity and non-conformity may or may not be documented. Examples of such non-conformities include but are not limited to:

1. transcription errors
2. grammatical errors
3. typographical errors
4. omission errors

B. Quality Action Correction (QAC Level 2): Action taken to correct a non-conformity when the non-conforming work is of some significance and the investigation demonstrates that the non-conformity did not affect the validity and accuracy of the test result. Level II non-conformities are typically observed and corrected prior to issuing a report and are addressed on a case-by-case basis. Non-conformities at this level do not affect or cause immediate concern for the fundamental reliability of the work product. Technical non-conformities may include but are not limited to:

1. A contamination event but the contaminant is subsequently demonstrated not to affect the validity, reliability, and accuracy of the reported results.
2. A sample switch but the switch is subsequently demonstrated to not affect the validity, reliability, and accuracy of the reported results.
3. Improper use or no use of controls, but it is subsequently demonstrated that it did not affect the validity and accuracy of the reported results.
4. Use of expired kits or reagents or non-QC’d kits and reagents, but it is subsequently demonstrated that it did not affect the validity and accuracy of the reported test results.
5. Omission of quality control check measures, but it is subsequently demonstrated that the omission did not affect the validity and accuracy of the reported test results.
6. The use of non-calibrated or performance checked equipment, but it is subsequently demonstrated that the equipment is in good working order and its use did not affect the validity and accuracy of the test results.
7. When equipment fails or a procedure fails, but it is subsequently demonstrated that the failure did not affect the validity or accuracy of the test.
8. Using an improper procedure or deviating from a protocol, but it is subsequently demonstrated that the deviation did not affect the validity and accuracy of the test results.
9. Level 2 non-conformities typically will be identified by the analyst or observed during the review process. These non-conformities typically will be corrected by repeating one or more of the testing processes or analysis steps, if possible. If the corrective actions taken demonstrate that the results are reliable and accurate, the results can be reported.

10. When the non-conformity is not or cannot be corrected, such as with the use of an expired kit or reagent, it must be shown that the non-conformity did not affect the reliability and accuracy of the results.

11. Level 2 non-conformities will be documented in the case notes. The analyst will describe the "issue/problem" in the case notes and the notes will contain what corrective actions were taken, if applicable, to rectify the non-conformity.

12. A Level 2 will be documented in LIMS using FSDF.23. The analyst or unit supervisor will document the following aspects, if applicable:
   1. A summary of the event
   2. Analysis, including any troubleshooting and investigation
   3. Corrective actions taken to address the non-conformity

13. The Unit Supervisor and/or DNA Technical Leader will review the documentation and have the discretion to determine the appropriate course of action.

C. Quality Action -Correction (QAC Level 1): Action to address a significant technical or quality issue. Level 1 non-conformities may include but are not limited to:
   1. When there has been an erroneous test result/conclusion reported in casework or proficiency test
   2. When there has been a misidentification of a biological substance reported in casework or proficiency testing
   3. When test results or records have been falsified
   4. When erroneous or falsified testimony has occurred
   5. When the original evidence has been lost, destroyed or compromised by some action or event that occurred within the laboratory
   6. When PCR contamination is detected in non-PCR designated areas.
   7. Audit findings.
   8. See FSD.15 for information regarding the elements of a Quality Action Correction-1.

IV. Documentation and Retention

A. Documentation of level one and two corrective actions are maintained by the Laboratory in LIMS, according to FSD procedure QA.18. Documentation will be retained according to Control of Records Division Policy (FSD.44). (QAS Std 3.2)

V. Review and Monitoring

A. Level 2 corrective actions are reviewed at the time of each incident by the Unit Supervisor, and DNA Technical Lead, if DNA related. Additionally, level 2 corrections are annually reviewed during the Unit's Annual Quality Review, as specified in BIO.5.QAQC.03, and as part of the DNA Quality Assurance Standards.

B. Level 1 corrective actions are monitored for effectiveness for the period of time specified in the Corrective Action Report by the Unit Supervisor and DNA Technical Leader, if DNA related. The Corrective Action may be closed if the monitoring finds that the corrective actions taken have been effective.

END OF DOCUMENT
I. Audits are an important part of the Quality Assurance Program. An audit is designed to evaluate the laboratory's performance through examining policies, procedures, and records pertaining to the overall quality system.

II. The Biology Unit undergoes an annual quality audit. See the Division Manual on Quality Audits (FSD.20) for further information.

III. DNA Quality Assurance Audit

1. The DNA section of the Unit is audited annually in accordance with the DNA Quality Assurance Standards for Forensic DNA Laboratories. QAS 15.1

2. A DNA audit will be conducted once every calendar year. The date between audits must be greater than 6 months apart and no more than 18 months apart between one calendar year to the next.

3. At least once every two years, an external audit must be conducted by a team of auditors from external laboratories. QAS 15.2

4. Regardless of whether the audit is internal or external, one or more of the auditors must be a qualified or previous qualified analyst(s) qualified for each of the DNA technologies and platforms used in the laboratory.

5. At least one of the audit team members must be a “qualified auditor”: a person who has successfully completed the FBI Quality Assurance Auditor course.

6. Documentation of internal and external audits, as well as the auditor’s qualifications will be maintained by the Biology Unit. QAS 15.2 a, b and QAS 15.3 a, b

7. Audit documentation for individuals who have had their qualifications evaluated and approved during two successive external audits will be maintained. QAS 15.2.1

   a. DNA analysts, the casework CODIS Administrator, and DNA Technical Lead who have not had their training qualifications evaluated and approved for two successive external audits, will continue to have their experience, education and training qualifications reviewed until at least two external audits.

8. Audit documentation for validations that have been previously evaluated and approved during one external audit will be maintained. QAS 15.2.2

   a. DNA validation studies that have not been previously reviewed and evaluated through one external audit will continue to be reviewed and documented until at least one external audit.

9. The internal and external audits will be conducted using the most current FBI DNA Quality Assurance Standards Audit document. QAS 15.4

10. DNA Quality Assurance Audit documents and findings are reviewed by the DNA Technical Leader. Findings from the Audit are addressed through the Corrective Action process (see Division Manual Non-Conforming Work FSD.15). The corrective actions are reviewed for approval by the DNA Technical Lead. This allows for audit findings to be appropriately addressed prior to any corrective action being implemented. QAS 15.5

11. A copy of all external audit documents, including the laboratory’s responses and corrective actions to any audit findings, will be provided to the NDIS custodian within 30 days of receipt of the audit document/report. QAS 15.1.1

   a. A copy of all audits (internal and external) along with the laboratory’s responses/corrective actions to any audit findings will be provided to the SDIS custodian.
12. Prior Quality Audit Documents including resolution of audit findings and corrective actions are retained in the Biology Unit by the DNA Technical Lead. The documents are retained minimally for 10 years according to Division Manual policy "Control of Records" FSD.44, QAS 3.2, 15.6

END OF DOCUMENT
An effective safety program in the workplace is an important part of every organization. Safety programs promote safe practices, and reduce injuries and illness. The Laboratory maintains a safety program that adheres to State and Federal regulations as well as to accreditation standards to ensure the safety of all employees.

### Safety Program

Part of an effective health and safety program is having a written safety manual which specifically states the issues and requirements regarding environmental health, safety and responsibility in the workplace. All examiners in the Biology Unit shall comply with the Division Safety Manual. (QAS 16.1)

Examiners in the Biology Unit receive and follow the blood borne pathogens and chemical hygiene training provided through the Division’s safety program (QAS 16.1.1). The blood borne pathogens and chemical hygiene training is conducted once a year. Examiner completion is documented by Laboratory management. (QAS 16.1.2)

According to FSD.08, the Safety Coordinator will oversee the Laboratory’s health and safety program and will oversee the annual review of the program. The annual review is documented through the Laboratory’s annual quality audit and retained according to FSD.20. (QAS 16.2)

### Biological Hazards

Biological hazards are biological substances that pose a threat to human health. Biological evidence contains biological hazards, such as bacteria, viruses, fungi, and parasites.

All examiners in the Biology Unit are exposed to biological evidence. All biological evidence must be treated as if it is hazardous. Proper protective equipment, cleaning, spill procedures and waste disposal are essential to the safety program to protect the employee from exposure.

### Safety Precaution Guidelines

1. Protect yourself
2. Protect others
3. Protect the evidence
4. Handle all biological materials and fluids with universal precautions
5. Body fluids, wet or dry, carry diseases
6. The key to safety is prevention.

### Exposure Prevention

**Personal Protective Equipment**

Personal protective equipment (PPE) is used to prevent the transfer of biological hazards and minimize the exposure and risk to the examiner. The examiner must be aware and consider the potential health risks at all times when handling biological evidence. PPE, such as gloves, goggles, and face masks, are the first line of defense in preventing exposure.

I. Gloves must be worn when handling evidence.

II. Contact with the face, nose, mouth, and eyes should be avoided, until gloves have been removed and/or hands have been washed.

III. Minimize contact with personal items or shared contact areas, such as phones, computers, and doorknobs while wearing gloves.

IV. Gloves must be discarded if they are suspected to have been contaminated with a biological substance.
V. Gloves and face masks need to be disposed of when contaminated with biological material, deteriorated, torn and when the laboratory examination is complete.

VI. Examination areas are physically separated from office and administrative areas. Laboratory coats are to be worn while examinations are being conducted and are not to be worn in the office areas.

VII. Lab coats should be changed frequently and are laundered through the Laboratory's laundry service.

Hygiene

I. As an extra precaution, hands and exposed skin should be washed frequently and after removing PPE.

II. Long hair should be tied back.

III. Eating, drinking, smoking, and gum chewing during the examination of evidence or in the examination area is prohibited.

Cleaning

I. Disposal and cleaning of equipment needs to be conducted in an appropriate manner to avoid exposing others to biological hazards.

II. Bench tops and shared work surfaces are routinely cleaned with a 10% to 20% bleach and water solution before and after the examination of evidence.

III. Disposable bench covers or butcher paper is placed on the bench top work area prior to use to capture potential shed biological material. The covers are disposed of after use, into the trash or biohazard container, depending on the amount of soiling.

IV. Shared equipment is cleaned during periodic scheduled maintenance.

Biological Spills

I. Biological fluid spills (e.g. digested, extracted DNA or blood) pose an immediate health threat and require immediate and specialized action.

II. Immediately contain and prevent the spread of the spill, by applying an absorbent material such as shop towels to block the further spread of the spill. Absorbent material available in spill kits may also be used, if needed.

III. Access to the area of the spill needs to be limited to those involved in the clean up.

IV. Appropriate PPE, such as gloves, lab coat, face shield, needs to be worn during the clean-up.

V. The spill area needs to be decontaminated with a 20% bleach solution and allowed to stand for at least 10 minutes.

VI. The towels need to be disposed of in biohazard containers.

VII. Spills involving amplified DNA: The spill needs to be cleaned up immediately with absorbent towels and the area needs to be decontaminated with a 20% bleach solution and allowed to stand for at least 10 minutes. If personal clothing was contaminated during the spill, the analyst must not return to the examination or extraction areas until the affected clothing has been removed. To protect personal clothing as much as possible during the clean up, PPE such as gloves, disposable booties and a lab coat may need to be worn. Dispose of the contaminated absorbent towels in a PCR waste container in the PCR room.

Chemical Spills

Information regarding the proper clean up procedures, including needed protective clothing, for hazardous chemicals can be found in the appropriate Safety Data Sheets.

When an emergency spill occurs, an employee typically will not have time to begin researching the proper emergency procedures before taking action. Therefore, it is critical that employees be familiar with the correct emergency action in the event of an accidental spill before using a chemical.

Each chemical may require a different response in the event of a spill, therefore certain general guidelines can be followed:

I. If an employee knows a chemical is not hazardous, he/she should clean up a spill in the appropriate manner as soon as possible.

II. If the employee knows that the chemical is hazardous, but is able to safely clean up the spill using available protective equipment as necessary, he/she must do so immediately.
A. If the chemical poses a contact hazard, the employee must ensure that other employees do not come into contact with the chemical.

B. If the chemical poses an inhalation hazard, the employee will ensure that employees without the proper protective equipment vacate the area.

III. If the employee does not know the identity of the chemical, does not know the correct clean up procedures, or it is beyond the capability of the laboratory to safely clean up the chemical, he/she will immediately vacate the area and advise other employees to leave also.

IV. Anytime an immediate clean up is not possible, the employee will notify his/her supervisor. If that supervisor is not available, then at least one of the following individuals must be notified in the order listed:

A. Immediate Supervisor or Designee
B. Another Division Manager
C. Division Safety Coordinator
D. Chief of Forensic Services
E. County Hazardous Materials (335-3200 or the 24 hour hotline 335-3232)

V. After evaluating the situation, the supervisor may determine that it is safe to proceed with cleaning up or may ask Hazard Materials personnel for advice or help with the clean up.

Refer to the Division Safety Manual, SAF.21 for further instructions on chemical spills.

Waste Disposal

I. Typically, materials that have wet biohazardous materials present on them and items soaked with biological fluids will be disposed of in biohazard waste containers.

II. Bench covers, wipes, gloves, pipette tips with the potential to have small amounts of biological material on them can be disposed of in trash cans.

III. Sharps, such as scalpel blades, razor blades will be disposed of in the Biohazard Sharps waste containers. The containers should not be filled past the "fill line" indicated on the container.

IV. Hazardous waste generated in the examination areas, such as screening reagents and extraction chemicals are placed in labeled chemical waste containers and when full or when the hazardous waste vendor picks up the waste, the containers are placed in the hazardous waste pick up area.

V. Waste contained in the PCR room, such as all tubes, tips, wipes, gloves, etc. used in the PCR room need to be disposed of only in the PCR waste container located in the PCR room. When full, the PCR waste container is removed by Biology Unit staff directly into waste containers located outside the laboratory. The PCR waste containers are not to be carried through any of the laboratory examination areas.

VI. Hazardous chemicals (formamide, polymer etc.) generated in the PCR room are placed in labeled plastic chemical waste jars located in the PCR room. When full, or when the hazardous waste vendor picks-up the waste, the containers are moved directly to the hazardous waste pick up area. The PCR hazardous waste containers will not be carried through the rest of the laboratory examination areas.

END OF DOCUMENT
I. The Biology Unit may review casework outsourced to a vendor laboratory for purposes of uploading the DNA profiles generated by the vendor laboratory into CODIS. The Biology unit will follow the FBI Quality Assurance Standards when engaging in outsourcing practices. The Biology Unit currently participates in outsourcing, but does not do subcontracting.

II. Definition of Outsourcing:

A. Under the FBI's Quality Assurance Standards, outsourcing is the utilization of a vendor laboratory that provides DNA services in which the Sheriff's Office laboratory agrees to upload the vendor laboratory's DNA data into CODIS. By agreeing to upload the vendor laboratory's DNA data into CODIS, the Sheriff's Office accepts ownership of the DNA profile as long as it resides in CODIS.

III. Requirements

A. The laboratory may enter into an outsourcing agreement only with a qualified vendor laboratory that meets the requirements of Standard 17 of the FBI Quality Assurance Standards. The vendor laboratory must demonstrate competency through documentation of training, accreditation and laboratory procedures.

B. Any DNA outsourcing agreement will require approval of the technical specifications between the Forensic Services Division and the vendor laboratory. Prior to the setup of an agreement, the following will be required of the vendor laboratory:

1. Documentation of the vendor laboratory's accreditation status with ASCLD/LAB or ANAB
2. Documentation of the vendor laboratory's compliance with the FBI Quality Assurance Standard; Documentation will specifically include the most recent external audit, any corrective actions implemented to address audit findings, and any additional audit documents generated during the course of the agreement.

C. Documentation of the above will be maintained by the Sheriff's Office laboratory. The DNA Technical Leader will be an approving authority of the technical specifications of the outsourcing agreement prior to its commencement. The DNA Technical Leader's signature on the agreement will signify review and approval of the technical specifications stated in the agreement.

D. Prior to initiating casework for the Contra Costa County Sheriff's Laboratory the vendor laboratory must have documented approval from the Sheriff's Office DNA Technical Leader that the laboratory will accept ownership of the DNA profiles developed by the vendor laboratory. The date of signature on the agreement will signify approval for the vendor laboratory to commence casework.

IV. Site Visit Procedure QAS 17.7

A. Prior to the commencement of casework analysis, the DNA Technical Leader, a designated individual from the Biology Unit, or the FBI will conduct an initial on-site visit of the vendor laboratory.

B. When the outsourcing agreement extends beyond a year, an annual on-site visit of the vendor laboratory will be conducted. Alternatively, an on-site visit performed by the FBI or another NDIS Laboratory using the same technology, platform, and amplification kits may substitute for the annual on-site visit. Their on-site visit will be reviewed and approved by the DNA Technical Leader. Documentation of the approval will be maintained in the Biology unit.

C. The DNA Technical Leader or designated employee of the laboratory who conducts the initial on-site visit, or annual on-site visit must be a qualified or previously qualified DNA analyst in the technology, platform, and typing amplification kit used to generate the DNA data.

D. The purpose of the site visit is to confirm that the vendor laboratory's performance is in compliance with the FBI Quality Assurance Standards. The site visit does not require a complete audit in accordance with the FBI Quality Assurance Standards, but should...
predominately entail a review of areas such as personnel, proficiency testing, evidence control, quality assurance program, facilities, and corrective actions.

V. Review of Outsourced Data QAS 17.4

A. Scope of Review

1. The Biology Unit will conduct a modified technical review of the vendor's data prior to upload of the vendor laboratory's data into CODIS and document the review using the "Vendor DNA Profile Review Checklist." QAS 17.5 & 17.6.

2. The Technical reviewer must be someone who is qualified or has been previously qualified in the technology, platform, and typing amplification kit used by the vendor laboratory to generate the DNA profile, and who is also currently in the DNA proficiency testing program to the extent they conduct casework. QAS 17.6.a. This may include the CODIS Administrator, DNA Technical Leader, a technical reviewer, an analyst qualified in the data being reviewed, or a contract employee.

3. The case file will be administratively reviewed according to Division Policy (FSD.18) and the Biology Technical Unit manual section on Administrative Review BIO.5.OAOC.12.

B. Review Procedure

1. A laboratory request is generated in LIMS.

2. The Assignment Notification Request Form and the "Vendor DNA Profile Technical Review Checklist" BIO.1.BIOF.03 are printed.

3. The vendor laboratory's report will be reviewed and the following information will be verified:
   a. Victim(s), suspect(s) and/or subjects names
   b. Agency and agency case number
   c. Correct item numbers
   d. Each tested item, or probative fraction is addressed.
   e. Reported results and conclusions are supported by the vendor's DNA STR data

4. The vendor laboratory's case documentation will be reviewed and the following information will be verified:
   a. Date laboratory received vendor data/documentation
   b. Vendor laboratory ID#/report# (if applicable)
   c. Verification of the vendor lab's technical review
   d. Methods, technology, and platform used (Quantification method, Typing Kits, and Electrophoresis platform)

5. Review of the vendor’s STR typing data will entail verification of either pre-printed electropherograms or the electronic data of all the samples and controls. If electronic data is to be reviewed, the appropriate genetic analysis software, such as GeneMapperID/ID-X software, will be used with the same analysis parameters used by the vendor laboratory and adhering to the vendor’s validation studies. The vendor’s parameters will be detailed in their protocols and procedures which are maintained and available on the Biology Unit’s Network.

6. The vendor laboratory's STR data will be reviewed and the following information will be verified:
   a. That expected results were obtained from all controls: sizing standard, ladder, positive and negative controls, and reagent blanks.
   b. Typing results, allele calls and any results tables.

7. The profile being entered into CODIS will be reviewed and the following information will be verified/recorded:
   a. If the sample meets the eligibility to be entered into CODIS
   b. Specimen category (Forensic Unknown, Mixture, etc)
   c. Specimen name
   d. Offense date
   e. Source ID
   f. Agency information
   g. If an elimination sample is needed/requested

8. The reviewer's initials and date on the "Vendor Laboratory DNA Profile Review Sheet" signifies the technical reviewers concurrence with the vendor's data and approval of the DNA profile for upload into CODIS.

9. After approval, the profile can be entered into CODIS. Note: for partial or mixture profiles, a CODIS match estimation will be calculated to determine if the profile meets SDIS/NDIS minimum match requirements for upload.
C. **Discrepancies:**

1. In the event there is a discrepancy between the review performed by the Biology Unit and the vendor laboratory, the reviewer will consult with the Unit Supervisor or the DNA Technical Leader. The vendor laboratory may be contacted to resolve the situation. The vendor laboratory may need to re-assess or take other corrective measures before ownership is taken for their DNA data.

2. The vendor laboratory's DNA profile may be uploaded if the cause of the discrepancy has been resolved and does not affect the interpretation of the DNA results/profile or outcome for the CODIS search.

3. The vendor's DNA profile may not be uploaded if the discrepancy cannot be resolved to the Biology Unit's satisfaction. The customer or vendor laboratory will be notified of the unresolved issue either verbally or via a laboratory report.

D. **Case Documentation**

1. The vendor laboratory's case note packet documenting the contents and review of the vendor laboratory's data will be compiled and will consist of the following records:
   
   a. An Assignment Notification Form
   b. Any communication logs
   c. The vendor laboratory's final report
   d. Table of DNA typing results
   e. CODIS entry details (eligibility, specimen name & category, source ID, offense date, and agency name & case number)
   f. Match estimator calculation
   g. Print-outs of relevant electropherograms to support the results/conclusions
   h. Vendor DNA Technical Review Checklist
   i. LDIS Specimen Detail Report, if applicable
   j. CODIS Match Estimation, if applicable

E. **Laboratory Report**

1. The reviewer will generate a “Record of Notification Report.” The report will serve as notification to the customer (law enforcement agency or other law enforcement laboratory) that a DNA profile was uploaded to CODIS, or not uploaded, if the profile is determined to be ineligible.

2. The report will clearly state that the profile was generated by the vendor laboratory.

3. The technical reviewer will "Draft Complete" the request in LIMS as the "Analyst." This will signify the technical review of the vendor laboratory's data.

VI. **Release and Retention**

A. After administrative review, the completed laboratory case packet and report will be retained by the Clerical Unit. The report is sent to the client agency and not to the vendor laboratory unless the vendor laboratory is the client agency. The vendor laboratory's data will be retained either on CD/DVD or electronically in LIMS, or on the laboratory's internal network drive.

<tr>
<td>Quality Assurance/Quality Control</td>
<td>Equipment Quality Control Check Schedule</td>
</tr>
</tbody>
</table>

I. The Biology Unit maintains a schedule for the quality control checks of equipment and instrumentation and uses inspection record forms and logs to document the actions taken. The following is the quality control check schedule and reference to the quality control check procedures:

A. **Weekly Checks**

1. Refrigerators/Freezers (temperature monitoring). QC Procedure: BIO.5.QAQC.24

B. **Monthly Checks**

1. pH meter (fluid check). QC Procedure: BIO.5.QAQC.24
2. Lab Cleanup. QC Form BIO.5.QAQCF.43
3. 7500 background

C. **Quarterly Checks**

D. **Every Four Months**

1. Versa volume calibrations. See BIO.5.QAQC.25

E. **Semiannual Checks**

3. EZ-1 Robots. QC Procedure: BIO.5.QAQC.25
4. Real Time PCR Instruments (ROI, Optical, Pure Dye Spectra). (One of the semiannual checks must be performed by a service technician). Computer maintenance. QC Procedure: BIO.5.QAQC.26
5. Genetic Analyzers, computer maintenance. QC Procedure: BIO.5.QAQC.27

F. **Annual In-house Checks**

1. Thermal Cyclers (System Performance, Temperature Verification and Temperature Uniformity checks). QC Procedure: BIO.5.QAQC.26
2. Water Purification System (filters replaced annually or as needed). QC Procedure: BIO.5.QAQC.24
3. Heat blocks, Oven, Refrigerators/Freezers (temperature checks with NIST traceable thermometer). QC Procedure: BIO.5.QAQC.24
4. EZ-1 Robots. QC Procedure BIO.5.QAQC.25
5. Digital Thermometers (replace batteries, as needed).
6. M-VAC. QC Procedure BIO.5.QAQC.24

G. **Calibrations/Maintenance Performed by Outside Vendor**

1. Digital reference thermometer (by Rice Lake) Frequency of calibration is indicated on certification paperwork
2. Temperature verification kit for thermal cyclers (Annually by Alpha Technics)
3. Pipettes (Annually by Ranin)
4. Balances (Annually by Rice Lake)
5. Weights (calibrated every 2 years by Rice Lake)
6. Microscopes (Annually by TI)
7. PCR/Chemical Fume Hoods (Annually by TSS)
8. Qiagen EZ1 XL robots (Annually by Qiagen)
9. Liquid Handling Robots (Annually by Hamilton)
10. Real Time PCR Instruments (Annually by Applied Biosystems)
11. Genetic Analyzers (Annually by Applied Biosystems)
12. Versa Robot (Annually by Aurora)

H. Annual Performance Check using NIST traceable DNA reference samples QAS 9.5.5: Instructions and records for the annual performance check of DNA procedures using the following instrumentation is found on the Laboratory's internal network drive.

1. Qiagen EZ-1 and EZ1 XL Robots
2. Liquid Handling Robots
3. Real Time PCR Instruments
4. Thermal Cyclers
5. Genetic Analyzers

END OF DOCUMENT
I. Contamination Prevention and Control (QAS 9.7)

A. There are several possible sources of contamination including but not limited to:
   1. Laboratory personnel
   2. Laboratory environment (i.e., surfaces, equipment, ventilation system)
   3. Cross contamination from another evidence item
   4. Consumables and reagents

B. Contamination can occur directly or indirectly
   1. Direct Contamination: Transfer of DNA from the source of contamination to the evidence item or DNA sample. This may occur when staff are handling an item but may also occur without direct physical contact such as speaking, sneezing, or coughing on an item or DNA sample.
   2. Indirect Contamination: Transfer of DNA from the source to the evidence or DNA sample through an intermediary such as pens, packaging, and lab surfaces.

C. Personal Protective Equipment
   1. Lab coats, gloves, and masks are required when handling evidence. Optionally, head covers, sleeve extenders, and face shields can be worn when handling evidence.
   2. Masks are required for all individuals examining evidence or any individual that will be entering the examiner's workbench area, PCR setup area, EZ1 extraction robot work area, or reagent preparation area.
   3. Head covers shall be worn during extensive screening of biological evidence, and may be worn at any stage of examination.
   4. Laboratory coats are changed when soiled or when determined to need laundering by the examiner. Lab coats are cleaned through a laundry service contracted by the laboratory. PCR coats are laundered on an as needed basis separately from general laboratory coats.
   5. Gloves are changed or decontaminated between examination of items, whenever contaminated, or when suspected to be contaminated with biological substances or DNA material.
   6. Gloves are changed after touching areas that may come in contact with ungloved hands (i.e., door handles, exterior evidence packages).
   7. Gloves should be changed after a set of transfer steps within a procedure, between different DNA extraction batches, and after touching a camera or computer keyboard.
   8. If adjusting a face mask with a gloved hand, gloves should be changed before handling evidence or samples. Avoid touching one's face or hair with gloved hands.
   9. For extra precaution, the examiner should wash their hands frequently.

D. Personnel
   1. Access to the biology unit is limited to biology unit staff.
   2. Activity in the examination area should be restricted to conducting laboratory procedures.
   3. Avoid talking while in the examination area. Food, drinks, and gum are not allowed in the examination area.
   4. Evidence examination should be avoided when sick and coughing/sneezing excessively.
   5. Collect DNA reference samples from anyone entering the evidence examination area, if possible.
6. Portable music devices and cell phones can be used to listen to music during examination, but must not be handled or placed on examination tables.

E. Cleaning

Analysts are responsible for maintaining a clean work area and general lab cleanliness. To control against biological contamination, the following procedures on cleaning and decontamination, and sterilization of equipment and work surfaces to prevent contamination of the evidence is to be followed:

1. Bleach dilutions should be prepared fresh weekly.
2. Bench tops, work surfaces, work space hoods, centrifuges, pipettes will be cleaned with a 10% bleach minimally before and after use.
3. Bench tops should then be covered with clean bench paper or diaper paper.
4. Personal examination tools, such as forceps, scissors, tube de-cappers pens, rulers, etc., are cleaned with 20% bleach, and rinsed with water or ethanol, minimally before and after use and ideally between each specimen.
5. Where practical, disposable supplies are used, such as razor blades and scalpels.
6. Tube racks and pipettes are cleaned with a 20% bleach solution, minimally after use.
7. Glassware is washed after use with laboratory detergent, rinsed thoroughly with tap water, and then rinsed thoroughly with distilled water. Heavily soiled items may be soaked for several hours. For greases and oils, a more rigorous cleaning may be needed using organic solvents (e.g. alcohols, acetone).
8. The PCR setup hoods are additionally decontaminated with the hood’s built-in UV light, after each use.
9. Any spilled chemicals are brushed off balances with dry, lint free wipes. Pans may be removed for cleaning in a sink, if needed, but must be thoroughly dried before replacing back on the balance.
10. Additionally, common areas of the Biology laboratory will be cleaned an a monthly basis.

F. Reagents and Consumables

1. When possible consumables should be purchased that are ISO 18385 compliant (DNA grade)
2. DNA reagents are prepared in the designated reagent preparation room.
3. Keep reagents closed when not in use.
4. A separate single use barrier pipette tip is used for each sample transfer and then discarded.
5. Steam Sterilization (Autoclaving) Steam sterilization provides a means to destroy bacterial organisms and proteins such as nucleases. Steam sterilization will damage endogenous DNA, however it may not completely be effective in destroying all template DNA viable for PCR.
   a. Glass containers used to prepare DNA critical reagents are autoclaved either prior to use, or at the same time as a reagent requiring sterilization. Autoclave tape on the containers is used to indicate appropriate sterilization conditions were met.
   b. Reagent preparation logs specify which reagents require steam sterilization. Containers will be labeled with autoclave tape to indicate sterilization conditions were met.
   c. Plastic tubes used in the extraction, recovery, storage, and amplification of DNA are to be sterilized prior to use, if not purchased in a sterilized condition. Only appropriate types of plastics (e.g. polypropylene, polymethylpentene, polypropylene copolymer, etc.) are to be autoclaved.
   d. Autoclave the tubes in autoclave packs or in an open container which allows the tubes to receive maximum even exposure to the steam.
   e. Label the packs (if no autoclave indicator is present) or the apparatus with autoclave tape to show that appropriate sterilization conditions were met.
   f. After sterilization, allow packs to cool and store for use. If tubes are in an open container, transfer tubes into a clean closeable container(s) labeled containers with initials, date, and autoclave status.
   g. Tube storage containers should be autoclaved periodically.

G. Contamination Prevention during Sample Handling

1. Each evidence item is placed on a fresh piece of paper or other suitable disposable material.
2. Exterior evidence packages and paperwork that may have been handled with ungloved hands should not be placed on the same paper that evidence examination is taking place.

3. DNA digestion is performed on a different surface than evidence examinations, by placing new bench paper or diaper paper down, or using a separate area of the workstation.

4. To avoid fluid dispersal from the sample tube or the cap when opening, briefly centrifuge sample tubes to remove fluid or condensation that may have accumulated at the top of the tubes.

5. Open sample tubes carefully and in a controlled manner using a decapping device or a fresh kimwipe.

6. Keep reagents and evidence tubes closed when not in use. Only one evidence item should be open at a time.

7. Transfer of liquid specimens is conducted over disposable absorbent paper. Dispersal of aerosols needs to be conducted in an appropriate fume hood.

8. DNA from evidence and reference samples must be sampled, digested, and extracted separately, either in time or space.

9. When possible, samples anticipated to contain low levels of DNA should be sampled, digested, and extracted separately, either in time or space from high level DNA samples.

10. Samples known to originate from the victim, such as a vaginal swab must be sampled, digested, and extracted separately, either in time or space from suspect samples (i.e penile swabs).

11. Where practical, handle low level DNA samples, such as touch DNA or hair samples, prior to samples with higher concentrations of DNA or extract and recover at different times or space.

12. Examination paper should be carefully folded up and discarded to contain any inadvertent material from being dispersed throughout the examination area.

H. Prevention of amplified DNA contamination: In addition to physically isolating the area where amplified DNA is generated and handled, the following additional steps are taken:

1. All activities involving the handling of amplified DNA are confined to the PCR room.

2. Dedicated equipment and supplies located in the PCR room are specific for use only with amplified DNA procedures, such as thermal cyclers, pipettes, glassware, centrifuges, and genetic analyzers.

3. Non-disposable sample tube racks carried into the PCR room will not leave the PCR room unless it has been thoroughly cleaned (e.g. bleach, ethanol) and then must be thoroughly cleaned again once removed from the PCR room.

4. To avoid fluid dispersal when uncapping a PCR product tube, briefly centrifuge to remove possible fluid or condensation inside the cap. Open tubes carefully, using a decapping device or kimwipe.

5. PCR product remaining after typing is stored in the refrigerator/freezers in the PCR room until discarded. Discarded PCR product is packaged into press lock bags prior to being placed in the trash. The trash is carried out of the PCR room by Biology staff to ensure the trash does not get carried back through the examination and extraction rooms.

6. Lab coats are dedicated to the PCR room and are visually distinguishable by color from other laboratory coats. PCR lab coats are not to leave the room except to be laundered.

7. Gloves must be removed before leaving the PCR Room. As an extra precaution, the examiner should wash their hands immediately after leaving the room.

I. See BIO.2.DNA.10 for information on detecting, investigating, and managing contamination.
I. Purchasing Reagents and Supplies that affect the quality of tests

A. Selection
1. Most reagents and supplies in the Biology Unit are purchased solely for use by the Unit. These reagents and supplies are selected for their specific use in DNA testing.

2. The Biology Unit Supervisor's will evaluate vendors of externally provided products to ensure their suitability for use in testing. Reagents and supplies are selected based on one or more of the following criteria:
   a. The vendor’s product is specified by the technical procedure
   b. The vendor supplies a certificate of analysis specifying the grade (e.g. molecular grade)
   c. The vendor providing consumables is the manufacturer of the instrumentation they are used with
   d. The vendor provides products that are forensic grade, pre-sterilized, or DNA free
   e. The laboratory has a prior history of satisfactory service with the vendor product

3. Evaluations of reagents and supplies can be conducted by:
   a. Reviewing the product's certificate of analysis to ensure it is the proper grade needed for DNA testing
   b. Reviewing the products shipping documents
   c. Checking the products performance during QC testing
   d. Checking the products performance through validation

4. A vendor's products will be re-evaluated on an on-going basis through the use of controls and QC testing.
   a. If an issue occurs involving a consumable/reagent it should be brought to the attention of the Unit Supervisors and action will be taken.
   b. Actions could involve contacting the vendor to report the issue or replacing a particular lot with a new lot.

5. The Biology Unit's list of approved vendors for supplies and reagents that affect the quality of tests is maintained on the laboratory's internal network.

B. Ordering Procedure
1. The Biology Unit purchase list is located on the laboratory's internal network.

2. Supplies and reagents may be placed on the purchase list by any personnel within the Biology Unit.

3. The requirements for externally provided supplies will be communicated to the vendor through the Unit's purchasing documents. This will include the item description, catalog #, and any specifications the Unit requires of the product, such as forensic grade, or DNA free.

4. The staff member forwards the purchasing sheet to someone with budgetary authority (i.e., a Manager or the Chief) to obtain final approval to place the order.
5. The staff member then places the order and forwards the purchasing sheet into the Clerical Unit for record keeping.

C. **Receiving Procedure**

1. When supplies are received the shipping documents must be reviewed and the items inspected to verify that all the supplies ordered were received and that they conform to the Unit's requirements for externally provided products. This review should include checking to see if the correct part/catalog number was received.

2. If they do not conform to the Unit's requirements or the correct product was not received, the Unit will not accept the products, the Supervisors will be notified, and the vendor will be contacted.

3. If the Unit accepts the product the packing form should be signed and dated by the individual receiving the order.

4. The signed packaging slip should be forwarded to the Clerical Unit.

D. **Storage**

1. Commercial reagents and supplies are stored according to manufacturer specifications.

E. **Labels, Lot Numbers, and Expiration Dates**

1. As commercial reagents and supplies are received by the Biology Unit, the item(s) or the immediate internal packaging are to be labeled with the date of receipt and the initials of the person who received it.

2. The manufacturer generally labels commercial reagents with the identity of the reagent, lot number, and expiration date. If the reagent lacks any of this information, the laboratory will add in the missing information.

3. If an expiration date is not provided by the manufacturer, the laboratory will assign it a five year expiration from the date received (unless otherwise noted on the reagent preparation log).

4. If commercial reagents are aliquoted, the individual aliquot containers are to be labeled with the reagent name and any additional original manufacturer information, including the lot number and expiration date when possible.

5. Specific lot information and/or any quality control information provided with the commercial reagent or supply are to be recorded and maintained in the Biology Unit's Reagent Preparation Log.

II. **In-House Reagents**

A. The Biology Unit maintains a Reagent Preparation Log which is a collection of all the individual reagent log sheets for each reagent prepared in-house and commercial reagents bought for use within the Unit.

B. The preparation instructions for each in-house reagent is recorded its own reagent-specific log sheet. The sheet is filled out each time a reagent is prepared with the following information, as applicable:
   1. Reagent name
   2. Lot number, tracking number
   3. Date and initials of person preparing the reagent
   4. Expiration date
   5. Purpose of reagent
   6. Preparation instructions
   7. Storage conditions
   8. Manufacturer and lot number of each component used to make the reagent
   9. Quantity of each component used
   10. Procedure for QC testing the reagent
   11. QC check info: performed by and date and individual approving QC testing
   12. Specific hazards associated with the use or production of the reagent

C. **Labels, Lot Numbers, and Expiration Dates**

1. In-house reagents or aliquots are labeled with the following information listed below. A container holding much smaller aliquots may be labeled on the exterior of the container with all the information in place of each individual aliquot.
   a. Name of reagent
   b. Lot number (mm/dd/yy of preparation followed by initials of preparer)
   c. Tracking number (a sequential number for batching the critical reagents)
   d. Expiration date (optional)
   e. Hazard label

2. The expiration date for each in-house prepared reagent is specified on the respective reagent preparation form.
3. Most critical in-house prepared reagents are given an 18 month expiration date from the date of preparation, unless otherwise specified in the reagent log procedure.

4. In most cases, the initial expiration date of a reagent is the only valid expiration date. However, an expiration date of an in-house reagent may be extended once the reagent is re-qualified through a quality control check that demonstrates its continued reliability and effectiveness. The expiration date may be extended in three month intervals and must be approved by the Unit Supervisor or the DNA Technical Leader. An approved extended reagent takes on a modified lot number, such as the initial mm/dd/yy followed by "A", or a modified tracking number, if applicable.

III. Critical Reagents

A. Critical reagents are reagents and supplies that have a significant effect on the quality of testing.

B. The following reagents are deemed critical reagents and are quality control tested prior to use in casework:

1. Stain Extraction Buffer
2. Proteinase K
3. Dithiothreitol (DTT)
4. TE-4
5. Phenol Chloroform
6. DNase I
7. Tween 80
8. EDTA
9. CaCl\(_2\) + MgCl\(_2\)

IV. Critical Commercial Kits

A. The following commercially available kits are deemed critical and are quality control tested prior to use in casework:

1. Qiagen Investigator Kit
2. PowerQuant Quantitative PCR Kit
3. PowerPlex Fusion 6C
4. PowerPlex Y23
5. PowerPlex Swab Solution

B. Labels, Lot Numbers, and Expiration Dates

1. The commercial kits listed above are pre-labeled by the manufacturer with the name of the reagent, manufacturer lot number, and expiration date. Upon being quality control tested with the Reagent Quality Control procedure below, the commercial critical reagent is then additionally labeled with the following information:

   a. Tracking number (a sequential number given for each lot of commercial reagent or kit)

   b. Quality Control check info (mm/dd/yy followed by the analyst's initials)

2. In general the manufacturer’s expiration date for commercial kits is adopted. However, the expiration date for a commercial critical reagent may be extended if the reagent is re-qualified through a quality control check demonstrating its continued reliability and effectiveness. The reagent expiration may be extended in three month intervals with the approval of the DNA Technical Leader or Unit Supervisor. An approved extended reagent takes on a modified tracking number and is labeled with the re-qualified quality control check date. See Reagent Quality Control Procedure below.

V. Critical Reagent QC Checks

A. Each new commercial kit lot or in-house lot of critical reagents is quality control tested prior to use with casework.

B. Multiple commercial kits of a given type, such as the Qiagen Investigator Kit, PowerQuant System, PowerPlex Y23, or PowerPlex Fusion 6C System, are quality control tested as a batch when the kits share the same manufacturer's lot number. The reagents tested in one kit represent reagents for all kits with the same lot number.

C. If the quality control indicators do not meet the quality specifications, notify the Supervisor and the DNA Technical Leader to evaluate the data. Additional testing may be required.

D. Reagents that fail this quality control check cannot be used for casework. The Unit will notify the vendor that the provided product does not meet our specifications.

E. The signature of the DNA Technical Leader, Unit Supervisor, or an individual as authorized by either, signifies approval for casework.
F. The quality control procedure and specifications for passing the QC check for each critical reagent and kit are found in the following reagent forms below:

1. Qiagen Investigator Kit, see form BIO.5.QAQCF.29
2. Phenol-Chloroform-Isoamyl Alcohol, see form BIO.5.QAQCF.20
3. PowerQuant Quantitation Kit QAS 9.3.1, see form BIO.5.QAQCF.30.01
4. PowerPlex Fusion 6C DNA Amplification/Typing Kit QAS 9.3.1, see form BIO.5.QAQCF.26.01
5. Stain Extraction Buffer, see form BIO.5.QAQCF.23
6. Proteinase K (20mg/mL), see form BIO.5.QAQCF.21
7. Dithiothreitol (DTT), see form BIO.5.QAQCF.22
8. TE-4, see form BIO.5.QAQCF.24
9. Tween 80, see form BIO.5.QAQCF.27
10. DNase I, see form BIO.5.QAQCF.28
11. EDTA, see form BIO.5.QAQCF.28
12. CaCl$_2$ + MgCl$_2$, see form BIO.5.QAQCF.41
13. Swab Solution, see form BIO.5.QAQCF.42
14. PowerPlex Y23, see form BIO.5.QAQCF.44
I. Test records are administrative records and technical records generated or received by a laboratory pertaining to testing performed, and may be stored in one or more locations.

   A. The case file is a part of the test record that contains the report, and a portion of the technical and administrative records for a particular case.

   B. Technical records must be sufficiently detailed that in the absence of the analyst, another competent analyst or supervisor could evaluate what was done, interpret the data and understand the basis of the conclusions.

II. The test record will consist of the following administrative and technical records (as applicable). The records can be found in the case file unless stated otherwise below.

   A. Test Report (See BIO.5.QAQC.11 for information regarding biology reports.)

   B. Laboratory Request Form: An administrative laboratory form that functions as the agency’s official request for service. The form captures the client’s case information, the list of evidence submitted and/or associated with the case, the specific laboratory examination(s) requested, and any associative information, such as where or whom the evidence originated (victim, suspect, or the crime scene).

      1. Changes to the request will be documented in the case packet or electronically in LIMS. Any correspondence with the client agency will include the name of the person authorizing the changes and the date of the change.

      2. A request form is required for all evidence examined in a particular case.

   C. Correspondence: Any records of phone conversations or e-mail communications regarding the specific case. These may be printed and placed in the case file or recorded electronically in LIMS.

   D. Case synopsis: Relevant case facts that have an impact on the evidence or its evidentiary value. It may include background information and case history gathered from police reports, medical examinations, and any correspondence with the client agency. The synopsis helps clarify the purpose of the laboratory examination or activity, and CODIS eligibility. The request form may include a synopsis written by the requesting agency.

   E. Previous laboratory request documents: Copies of previously reviewed laboratory requests may be included in the case notes for the purposes of documenting or providing a relevant link between the two examinations. The examinations may have been performed by the same examiner or another examiner and may be included in the case notes. This could include copies of documents such as previous reports, examination notes, and photos. Copies need to be clearly identified as a “copy”.

   F. Examination notes:

      1. Item numbers of the evidence received and a description of the items examined needs to be included in your case notes. The full itemized inventory of the evidence will be maintained in LIMS.

      2. Relevant or significant observations regarding the condition of the evidence and the presence of staining on the examined items. The size of any stains, number of swabs and any staining on the swabs will be noted. This can also be done through the use of a photograph.

      3. All items received by the laboratory shall have an outer package that is tape sealed and initialed, therefore this information does not need to be included in the case notes. A note should be made if the outer package is not tape sealed and initialed or contains the "RWI" stamp. The description of an item's outer packaging is included in the LIMS item descriptions. The condition (tape sealed, closed, etc) and description of any inner packages should be noted.
4. Diagrams and Photographs:

   a. All examined items and consumed swabs should be photographed prior to testing to document its original condition. Additional photographs may be taken to document an area or location where a stain was tested or sampled. Not all photographs taken need to be incorporated into the examination notes as long as a thumbnail printout of all retained photographs is included in the case notes. All screening test cards (for example, p30 and RSID cards) must be photographed or photocopied and placed in the case notes. If a test band is too light to be seen in a photograph/photocopy then a second qualified individual will have to confirm the results and add their initials and date.

   b. Photographs in the examination notes will be labeled with a description identifying what is being depicted in the photograph (for example, item #) and marked so that attention is drawn to specific observations, where applicable.

   c. If the examination notes contain a digital image that is altered, including cropping, or adjusting the brightness/contrast, this information should be noted in the examination notes next to the photograph.

   d. Digital images must be retained on the Laboratory's digital storage server. Information regarding their retention must be included in the case file.

   e. Photographs taken in the Biology Unit are used for general documentation purposes and are not treated as evidence for comparison purposes.

   f. Refer to Division Manual (FSD.42.01) for additional information regarding “Diagrams, Photographs, and Digital Images.”

G. Testing methods: All testing methods are to be documented in the case file and include:

1. The identification of all screening test methods used.

2. Instrumentation used and the operating parameters of instrumental analyses, such as the magnification, wavelengths, and any filters used for examination will be recorded in the case notes. Some instrumental parameters may be maintained electronically, such as those parameters associated with instruments for quantification (RT PCR) and STR analysis (Genetic Analyzers and STRmix).

3. For DNA analysis, the identification of the extraction and quantitative test methods used and a description of the DNA amplification kit(s) used must be included in the case file.

4. Screening quality control checks performed during testing (for example, positive and negative controls) and their results must be documented in the case notes, along with the lot numbers and expiration dates of all reagents and test kits used.

H. Examination Results: Examination results of all tests performed for each item examined must be documented.

I. DNA Specific Worksheets:

1. DNA data technical review sheet.

2. Digestion/Extraction worksheet(s) with DNA reagents and lot numbers.

3. Quantification worksheet with reagents and lot numbers.

4. Quantification results worksheet. (The real-time PCR run file will be maintained on the internal network drive)

5. Amplification worksheet(s) with sample concentration or dilution, reagents, and lot numbers.

6. Summary table(s) of DNA results (for binary interpretation methods only)

7. Documentation of CODIS profile eligibility, specimen name and category, and source ID. Printouts of any calculated minimum match estimates (MMEs) must also be included.

J. Electropherograms

1. Hard copies of electropherograms for all reported DNA evidence profiles used to substantiate reported conclusions are provided in the case file. For samples being interpreted using STRmix, copies of the electrophorograms with both stutter filters on and off must be printed in the case notes.

2. Control samples: Allelic ladders, reagent blanks, positive/negative amplification controls, size standards, and quality control samples, if applicable, are maintained electronically in the GeneMapper project within the GeneMapper run folder on the Unit's internal network drive. All raw data files are maintained on the Unit's internal network drive, even if they are not used
for reporting.

K. Records of Genemapper-IDX data edits to reported samples:

1. Edits made to controls and evidence samples are recorded electronically within the GeneMapper IDX project.

2. Edits made to reported evidence samples are also contained within the case file.

L. Interpretation notes or worksheets, if applicable.

M. Summary tables from previous requests, if applicable.

N. Statistical Analysis worksheets, if applicable

O. Propositions used for interpretation and statistical analysis, if applicable

P. STRmix Interpretation and LR from Previous Reports used for reporting must be included in the case notes. In some cases involving large STRmix reports, only the relevant portion of the report may be printed in the case notes. All STRmix reports and data will be maintained on the Laboratory's Internal Network drive.

Q. Disposition: The disposition will be included within the case file, on the test report, and will reflect:

1. A description that denotes the status of the original evidence (e.g., whether retained, returned or consumed), as well as any collected evidence (trace materials, swabs, stains) must be contained within the case file.

2. DNA extracts generated and if DNA extracts were consumed or returned. If returned, the submission they will be returned in will also be included.

R. Technical and Administrative Review Checklist: A checklist used by the analyst and the technical and administrative reviewers to review the required documentation and information.

S. LDIS Specimen Detail Report: A document that shows the DNA profile entered into CODIS.

T. Police Reports (if applicable)

U. Chain of custody: The official chain of custody is maintained in the Laboratory Information Management System (LIMS). The chain of custody at the time the case is submitted for review may be included in the case notes.

V. Use logs: Logs for the DNA equipment used in testing are maintained on the Unit's internal network drive.

III. General info regarding Case Notes

A. Examination notes, observations, data and calculations shall be recorded at or near the time they are made and shall be identifiable to the specific task.

B. The date(s) of testing/analysis will appear in the case notes so that it is clear on what date each activity was performed.

C. The notes can be LIMS generated, typed, or handwritten. See below for instructions on LIMS generated notes.

D. The laboratory case number, handwritten initials of the analyst or the secure electronic equivalent, date, and page number are required on every page of the case notes, with the total number of pages listed on the first and last page. This information is typically documented, either all or in part, in the upper right corner of the case note page.

E. When an examiner batches their work with another examiner, the examiner who performed the testing (if other than the reporting analyst) must be clearly identified on the shared worksheet with their handwritten initials or a secure electronic equivalent.

F. Abbreviations specific to terminology used in the Biology Unit will be defined or documented. A list of common abbreviations used by analysts in the Biology Unit may be found in BIO.1.BIO.12.01.

G. Any results produced by an outside laboratory that are relied upon and/or used for interpretation are to be included in the case notes. Identification of the laboratory that conducted the tests must be documented in the case notes.

H. When a planned deviation from a test method occurs, the Unit Supervisor and/or DNA Technical Leader must be aware of the deviation and it must be documented in the case notes.

IV. Review of and Corrections made to Case Records

A. Non-contemporaneous corrections made to notes must be tracked.

B. Corrections to handwritten records must have the analyst's initials and date of correction. The corrected text may include an insertion, or a deletion with a single line strikeout.
C. Corrections made to electronic records created outside of LIMS may be corrected by hand or electronically.
   1. Handwritten corrections must have the date of correction and the analyst's initials.
   2. If corrected electronically, a single line will be drawn diagonally across the original page. The page should include the date, analyst initials, and a brief explanation for the replacement. The replaced pages are retained within the case packet, typically at the end and will be page numbered as part of the case packet.
   3. If an observation, data, or a test result is amended, the reason it was amended and the identity of the individuals taking the action will be documented (This may be recorded on the technical/administrative review sheet).

D. Corrections made to electronic records created in LIMS will be tracked electronically in LIMS.
   1. If an observation, data, or a test result is amended, the reason it was amended and the identity of the individuals taking the action will be documented (This may be recorded on the technical/administrative review sheet).

Notes for Sexual Assault Evidence Kit (SAEK) examinations conducted directly in LIMS:

For the service type "SAEK", screening and evidence examination case notes will be recorded directly in LIMS. The following are directions on how to generate SAEK case notes.

1. Subitemize all evidence within the kit in LIMS. Items can be sub-itemized directly from the “Enter Findings” screen. This automatically relates them to the request.

2. Under the request number, right click, and select “Edit Findings.”

3. Select the main SAEK, right click, then select "Add Result.”
   4. Under the result type select "Bio Inventory" and hit "Apply.’

5. On the bottom right select the “…” icon. This will open a data tab where information for the items within the kit can be populated, such as: # of items, date of inventory, and condition.

6. Under each item tested, select the item, right click, then select “Add Result.”

7. If performing body fluid identification, under the result type select “Bio-Screen”. If proceeding directly to DNA select "Bio Swab" and hit "Apply’.

8. On the bottom right select the “…” icon. This will open a data tab where information about that item can be populated, such as: # of swabs, amount sampled, staining, test results, etc.

9. If performing body fluid identification, in the main narrative box, insert the conclusion for that item as it should appear on the report. For SAEKs taken directly to DNA testing, leave this narrative box empty.

10. For body fluid identification only: If the item is to be forwarded for DNA analysis, check the box, “Forward to DNA.” This will populate the item # under the items to be forwarded to DNA category in the report.

11. To add additional notes under a given item, right click “Add Result” and select “Notes" under that item. Any additional screening notes can be added to the case notes here.

12. Any items that do not have a result type, will automatically be placed in the Items Not Examined section in the report.

13. For biological fluid identification only: Add a disposition to the case notes: Right click on the request number and select “Edit Findings.” The General Analytical Module will open. Right click on the request and select “Add Result,” Select “Disposition” under Result Type, and type the disposition in the narrative field. The disposition will be added to the case notes and will automatically be added to the report.

14. Reagent lot numbers and QC control checks can be added under "Edit Findings" by selecting "Traceability" under the Result Type or alternatively, a QC sheet can be added via the imaging module.

15. Any notes/worksheets written outside of LIMS may be included in the case notes by using the JusticeTrax Image Module.
   a. The JusticeTrax Imaging Printing Preferences must be set to:
      i. Resolution: Low 200x200 DPI
      ii. File format: JPEG
      iii. Filename generation: use doc name
      iv. Output Directory: C:\Temp
   b. To add images to the case notes, click on the camera icon on the bottom left in LIMS to open the JusticeTrax Image Module
c. Click on the **Requests** tab in the Image Module and select the request number.

d. Click on the **Add New Image icon.**

e. Find your file in the C:\Temp folder

f. Name the file and click **OK.**

g. Image size should be less than 1000 KB and should always be checked before adding to the imaging module.

h. Files will be placed in the note packet in a particular order. Below is the order in which files will be added and what should be placed within each:

   i. **REQ:** These documents will be placed into the note packet before any examination notes.

   ii. **IMG:** This is for other communications such as emails or records of conversations not captured in LIMS, as well as any images of the evidence.

   iii. **DATA:** This can be used for any hand written notes or data printouts.

   iv. **QC:** The QC sheet can be saved using this designation. This will place the QC sheet at the end of the notes, but before the Technical and Administrative checklist. (for biological fluid identification only)

   v. Image names are sorted by prefix and then alphabetically. For example, “REQ01” will come before “REQ02,” and both will come before “IMG01”, etc. Prefixes that don’t match will go last. Additional remarks can also be added after the prefix to help label the images as to item number or image type: “DATA12 s:5 i:5-1-A P30 and amylase”, or “DATA13 s:5 i:5-1-A reagent traceability”. This will help the analyst or reviewer sort through a large number of images in the packet.

   vi. A copy of a blank Technical and Administrative checklist must be added as the last page in the note packet.

   vii. To print the notes, right click on the request number, select **“Edit Lab Notes”** and select the printer icon.

**LIMS Generated Notes for DNA Sample Selection**

When a DNA request consists of swabs only, the sample selection notes can be generated in LIMS. The following are the directions on how to generate sampling notes in LIMS.

1. Subitemize all evidence within the kit in LIMS. Items can be sub-itemized directly from the **“Enter Findings”** screen. This automatically relates them to the request.

2. Under the request number, right click, and select **“Edit Findings.”**

3. Select the outer package, right click, then select **“Add Result.”**

4. Under the result type select **“Bio Inventory”** and hit **“Apply”**.

5. On the bottom right select the “…” icon. This will open a data tab where information for the items within the kit can be populated, such as: # of items, date of inventory, and condition.

6. Under each item tested, select the item, right click, then select **“Add Result.”**

7. Under the result type select **“Bio Swab”** and hit **“Apply”**.

8. On the bottom right select the “…” icon. This will open a data tab where information about the swabs can be populated, such as # of swabs, visual condition, amount sampled, and if the sample was consumed.

9. If the swab is to be tested for the presence of biological fluids, the result type **“Bio Screen”** should be selected instead of **“Bio Swab.”**

10. Follow the directions pertaining to **“Bio Screen”** in the SAEK notes section.

**Case Documentation using Microsoft Surface Pro**

1. Turn on the Surface Pro.

2. Log in using the Sheriff's Office network account.

3. To incorporate photographs taken with the Surface Pro into case notes, open the camera app.
4. Tap the screen to focus on a particular area. Do not use the zoom feature. Tap the camera icon to take a photo.

5. Photos will be saved to the Pictures>Camera Roll folder.

6. Open Microsoft Word.

7. To insert a photo into Word, tap Insert at the top of the screen. Choose the photo from the Camera Roll folder.

8. To draw on the photo, tap Draw on the taskbar.

9. Save the Word document and photographs to the U:/ drive to access it from a desktop computer.

**Maintenance and Retention of Case Notes**

1. Once administratively reviewed, the case notes and report are transferred to the clerical area for filing into the case file. Clerical staff are responsible for the filing and maintenance of the case files.

2. Case records are stored in hard copy format in the case file and may be stored electronically within the laboratory’s LIMS system or on the Biology Unit’s network folder (for example GeneMapper data files).

**Release of Verbal Results and Case Notes:**

1. Verbal results can be provided to the customer, prior to a completed report, once the result(s) or relevant portion of results has been technically reviewed. A record of the verbal results provided to the client agency must be documented in the case notes.

2. Written examination results are not released until the report has been technically and administratively reviewed.

3. Release of case records is done according to Division policy on Control of Records. FSD.44

4. Physical access to case records is limited to the Chief, Managers, Supervisors, and clerical staff.

END OF DOCUMENT
The purpose of a quality control (QC) sample is to demonstrate that the DNA analytical process worked properly. A QC sample can be extracted and/or typed concurrently with evidence samples. The QC sample is from a previously characterized source, thus it serves as both an extraction control and as an additional known typing control for the DNA process. A quality control sample may be analyzed with a case request to demonstrate recovery and appropriate typing using the DNA protocols.

Guidelines:

1. A QC sample may be included in a digest/extraction set of evidence samples.
2. If cases are batched, a single QC sample may serve as the extraction control for all the cases as long as the samples within the batch are extracted under the same conditions. If monitoring for a different extraction method within the batch is desired, a second QC sample would be needed to monitor the extraction conditions.
3. If the QC sample is carried on to DNA typing the DNA analyst and technical reviewer will verify that the correct typing results were obtained. Verification of the correct results is documented by the technical reviewer on the DNA Data Technical Review Sheet.

Preparation of Quality Control Samples:

1. Dried blood swatches are prepared from known individuals or from liquid blood samples received from a Quality Assurance Testing body such as the College of American Pathologists (CAP) and Collaborative Testing Services (CTS) who's DNA type has been previously characterized.
2. The dried blood samples are placed into envelopes and given a unique identification number.
3. The number, along with the source information, is recorded in a QC Sample preparation log.
4. The dried blood samples are stored frozen in the Biology Unit's reagent freezer.
5. The QC Sample Log is maintained electronically and is accessible to all staff in the Biology Unit. The DNA analyst and technical reviewer will refer to the electronic log or to a answer key printed on Data Summary Table worksheet to verify that the correct DNA typing results were achieved.

END OF DOCUMENT
Performing planned maintenance on equipment is a quality control measure taken to ensure equipment is in good working condition and fit for its intended use.

A. Measures taken include cleaning, calibration, and inspection of equipment.

B. Records of checks are maintained by the Biology Unit on Inspection Record Forms BIO.5.QAQCF.03 and BIO.5.QAQCF.04.

**Alternate Light Source (ALS)**: Analysts are responsible for maintaining the operation and cleanliness of these instruments on a per use basis.

**Balances (QAS 10.2.1.2)**

1. Annually, balances are performance checked by a qualified outsider vendor. The balances must meet the manufacturer's requirement for calibration.

2. Documentation of the balance checks are maintained by the laboratory.

**Centrifuges**

1. Individuals are responsible for maintaining the operation and cleanliness of the centrifuges at their workstations.

2. Semiannually, shared centrifuges in common areas are cleaned and inspected to ensure they are in good working order.

3. **Cleaning Procedure**:
   
   a. Discard any counter weight tubes or size reduction tubes left in the centrifuge.

   b. Clean any trunnions with a bleach solution followed with deionized water.

   c. Wash and wipe the head and bowl with a bleach solution followed by deionized water.

**Evaporative Centrifuge**

1. Semiannually, the evaporative centrifuge is cleaned and inspected to ensure it is in good working order. The rubber gasket is inspected for brittleness.

2. **Cleaning Procedure**:
   
   a. The centrifuge is cleaned with a mild detergent soap solution and dried thoroughly.

   b. Lightly coat the drive shaft and rotor center with vacuum grease. Do not lubricate the cover O-ring.

   c. The acrylic top can only be cleaned with a mild detergent soap solution and water. Do not use solvents.

**pH Meter**

1. Calibrate the Beckman pH meter whenever a pH-specific reagent is prepared. Document the calibration on the reagent log form. The calibration is conducted using commercially available buffer standards to create an internal calibration curve. The pH meter conducts an internal diagnostic check at the time the calibration curve is determined.

2. **Procedure**: The calibration is conducted by selecting two appropriate standard buffers that bracket the desired pH of the reagent.

   a. Inspect the pH meter for signs of obvious damage.
b. Set the pH meter to Automatic Temperature Correct mode.

c. Remove the electrode bulb from the bulb reservoir, rinse the bulb and temperature probe with reverse osmosis (RO) water, and blot dry.

d. Place the electrode bulb and temperature probe in the standard pH 7 buffer and depress the STANDARD key. When the instrument has locked in the value for pH 7, remove the pH electrode and temperature probe, rinse with RO water, and blot dry.

e. Place the electrode bulb and temperature probe in the second pH standard (pH 4 or pH 10) and depress the STANDARD key again. When the instrument has locked in the value for the second standard, remove the electrode bulb and temperature probe from the standard buffer, rinse with RO water, and blot dry.

f. The pH meter is now calibrated for the range displayed on the LCD readout.

g. Repeat this calibration procedure for each reagent tested.

3. Monthly or as needed, conduct the following maintenance:

   a. Inspect the pH meter for signs of obvious damage.
   
   b. Replace the electrode junction solution.
   
   c. Replace the electrode solution in the bulb reservoir.

**Digital Reference Thermometer**

1. Annual Performance Check: The digital reference thermometer is considered a critical instrument and is performance checked against a NIST traceable calibrator by a qualified outside vendor (QAS 10.2.1.1). Documentation of the NIST traceable certification is kept in the Calibration and Maintenance Log. The digital thermometer must meet the manufacturer's tolerance for calibration.

**Heat blocks**

1. Before each use, the temperature of the heat block used for enzymatic digests is visually verified. If the temperature is outside of the prescribed temperature limits (e.g., 50 – 60°C), adjust the heat block accordingly while taking into consideration any offset recorded on the instrument. Recheck the temperature prior to beginning a digest.

2. Annual Performance Check: The thermometers in the heat blocks are performance checked in-house against the digital reference thermometer, which is annually performance checked against a NIST traceable thermometer by a qualified outside vendor.

   a. The set temperatures specified for the heat block’s intended use are checked against the digital reference thermometer.

   b. The temperatures of both the heat block’s thermometer and reference thermometer are recorded on the Thermometer Calibration Check Form.

   c. Any calculated offsets are recorded on the check form. The offsets are also recorded on the heat block for the examiner's reference.

   d. Any necessary temperature adjustments on the heat block should be made with the calculated offset in mind.

   e. Any instrument thermometer with an offset of greater than 10 ºC should be rechecked at a later time. If the same variance is observed, the instrument thermometer must be replaced.

3. Procedure:

   a. Place a microcentrifuge tube with sterile water into a well of the heat block.

   b. Place the probe of the digital reference thermometer into the microcentrifuge tube.

   c. Allow the temperature to stabilize for 5 to 10 minutes. When the digital display of the reference thermometer no longer fluctuates, record the temperature readings from both thermometers on the Thermometer Calibration Check Form.

   d. Calculate any offset. Record the offset on the check form and on the heat block.

   e. Make temperature adjustments to the heat block as needed.

**Refrigerators and Freezers**
1. **Weekly:** The temperature of refrigerators and freezers are monitored. Record the "Current Temperature" displayed on the unit's thermometer, as well as any "Lo/Hi" (or Min/Max) values on the Refrigerator/Freezer Weekly Temperature Check Form [BIO.5.QAQCF.06](#).

2. When applicable, clear the thermometer's Min/Max readings to begin the following week's temperature monitoring.

3. If the current temperature is outside the specified temperature range for the unit, actions may be need to be taken. In general, the temperature range for refrigerators is 2 to 8 °C and the temperature range for freezers is -30 to 2 °C.

   a. Monitor the temperature throughout the day to determine if it is a temporary temperature fluctuation. If the temperature falls back into compliance, record the final temperature. Record that the temperature was monitored in the "Comments" column.

   b. If the temperature continues to fall outside the acceptable range, adjust the thermostat of the refrigerator/freezer to compensate. Monitor the temperature for several hours or throughout the day. If the temperature falls back into compliance, record the final temperature. Record the adjustment in the "Comments" column.

   c. If the temperature continues to fall outside the acceptable range, the refrigerator or freezer may be taken out of service. Notify a Supervisor of the problem and place an "Out-of-Order" on the unit. Record the actions taken in the "Comments" column.

   d. After servicing, the equipment must be checked using the digital reference thermometer to determine a new offset value.

4. In the event that a weekly temperature check is missed, evaluate the preceding week's recorded temperature values with the current week's values. If both sets are within the acceptable range, the temperature range for the missing week can be considered to be in compliance.

   a. A Supervisor must be notified of the missed week's temperature monitoring, and upon review and if applicable, the missed record can be deemed "Compliant" in the "Comments" column. Include the initials and date of the individual performing the check. If the missing week cannot be considered compliant, monitor the temperature as in steps 1 to 3 above.

5. **Annual Performance Check:** The thermometer in the refrigerators and freezers are checked in-house against the digital reference thermometer. Checks are recorded on the Thermometer Calibration Check Form [BIO.5.QAQCF.02](#) and maintained in the Calibration and Maintenance Log.

   a. **Procedure:**
      1. For refrigerators and freezers, place the probe of the digital thermometer into the unit.
      2. Allow the temperature to stabilize for 5 to 10 minutes. When the digital display of the reference thermometer no longer fluctuates, record the temperature readings from both thermometers on the Thermometer Calibration Check Form.
      3. Calculate any offset.
      4. Record the offset on the check form and on the thermometer associated with the refrigerator/freezer.
      5. Make temperature adjustments to the instrument as needed.

**Temperature Verification System**

1. The temperature verification device used to check the well temperatures of the thermal cyclers is considered a critical piece of equipment ([QAS 10.2.1.3](#)) and is annually checked against a NIST traceable calibrator from a qualified outside vendor to meet the manufacturer's tolerance for calibration. Certification of the NIST traceable calibration is maintained in the Calibration and Maintenance Log.

2. Annually, the temperature verification kit is used to conduct in-house temperature performance verification of the thermal cyclers. See the procedure outlined in [BIO.5.QAQCF.26](#).

**Microscopes**

1. Annually, maintenance and cleaning is conducted on the microscopes by a qualified vendor. Documentation of the maintenance is retained by the Biology Unit.

**Steam Sterilizer (Autoclave)**

1. The autoclave has preset programs for different types of items to be sterilized (e.g., liquids, packs, etc).

2. Cleaning
a. At minimum, the autoclave is inspected, cleaned/descaled, and reservoir water drained and replaced with fresh water semianually.

b. Perform other preventative maintenance measures as outlined in Tuttnauer Operation and Maintenance Manual (pp 39-51) as necessary and document these additional maintenance activities in the Inspection Record Form BIO.5.QAQCF.04.

**Water Purification Systems**

1. Millipore Direct-Q 3

1. The Millipore Direct-Q 3 System has prompted display readouts for monitoring water quality. In general, the maintenance schedule is based on these readouts.

2. **Quarterly Monitoring**: Record the below values on the Water System Maintenance Log BIO.5.QAQCF.05:
   
   a. **Product Resistivity and Temperature**: The product resistivity and temperature are displayed automatically during DISPENSING mode or during RECIRCULATION.
   
   b. **RO Permeate Conductivity**: Press the “+” button. This displays the RO permeate water conductivity value. Note that the units are in mS/cm.
   
   c. **Pressure Gauge readings for the “IN” and “OUT” water feed**: The pressure gauges should read between 0.5-6 bars (15-90 psi). If the difference between the “IN” and “OUT” pressures is >1 bar, change the pretreatment pack as recommended by the Millipore vendor.

3. **Annual Maintenance** (see Direct-Q 3 System User Manual Rev. 2, 01/06, pp 37-56): The Direct-Q 3 System actively monitors the water pressure and quality of water to provide service alarm display warnings when these functions fall below acceptable values. Refer to the Direct-Q 3 System User Manual (p 62) to correct each situation. Document this maintenance in the Water System Maintenance Log BIO.5.QAQCF.05. The following are conducted annually, or as prompted by the service alarms:
   
   a. **Screen Filter Cleaning**: Perform every 12 months or as necessary.
   
   b. **Tank Level Calibration**: Refer to Direct-Q 3 System User Manual (pp 44-45).
   
   c. **Pretreatment Pak**: Replace every 12 months or as necessary.
   
   d. **System Sanitization**: During a system sanitization, the tank will also be sanitized. It is recommended to sanitize the system near the time of the SmartPak replacement (typically annually). The SmartPak, Final Filter, and Vent Filter all need to be replaced after the system sanitization is complete, and the flow calibration should also be performed.
   
   e. **Sanitization of the Tank**: If a system sanitization has been performed, then it is not necessary to perform a tank sanitization. The Vent Filter must be replaced after the sanitization is complete.
   
   f. **SmartPak Replacement**: Replace the SmartPak after a system or tank sanitization, when the Pak Alarm is displayed, or when the system resistivity display is blinking. Note that the Final Filter and Vent Filter must be replaced when the SmartPak is replaced and the flow calibration should also be performed.
   
   g. **Final Filter Replacement**: Replace the Final Filter when the SmartPak is replaced or when the Product Water flow rate drops. The Flow Calibration should also be done after the Final Filter is replaced.
   
   h. **Vent Filter Replacement**: Replace the Vent Filter when the SmartPak is replaced.
   
   i. **Flow Calibration**: Perform after the Final Filter is replaced or periodically.
   
   j. When performing the annual maintenance for the Direct-Q water system, perform the tasks in the following order:

   i. Inlet strainer screen filter (located inside the attachment coming from the wall. Turn off the water at the main valve first.)
   
   ii. Pretreatment Pak (located on the wall)
   
   iii. Sanitization of the System (which includes the tank- uses a concentrated hydrogen peroxide. See manual for grade and how to use sanitization kit)
   
   iv. Vent filter (disc looking filter at rear of the tank)
   
   v. Final filter (at the water dispensing point)
vi. Replace SmartPak (inside the Direct Q)

2. Millipore Direct 8

1. The Millipore Direct 8 System has prompted display readouts for monitoring water quality. In general, the maintenance schedule is based on these readouts.

2. Quarterly monitoring: Record the below values on the Water System Maintenance Log BIO.5.QAQCF.05:
   a. **Product Resistivity and Temperature**: The product resistivity and temperature are displayed automatically during DISPENSING or RECIRCULATING mode.
   
   b. **RO Permeate Conductivity**: The display shows the RO permeate water conductivity value. Note that the units are displayed in mS/cm.

3. Annual Maintenance (see Milli-Q Direct 8 System User Manual V2, 09/10, pp 72-94): The Direct 8 System actively monitors the water pressure and quality of water and provides service alarms and display warnings when these functions fall below acceptable values. Refer to the Direct 8 System User Manual to correct each situation. Document this maintenance in the Water System Maintenance Log BIO.5.QAQCF.05. The following are conducted annually, or as prompted by the service alarms:
   a. **Progard Pak Replacement**: Perform every 12 months or as necessary. The Progard Pak must be flushed after installation.
   
   b. **Tank Vent Filter Replacement**: The Progard Pak and Tank Vent Filter should be replaced at the same time. Refer to Millipore Reservoir User Manual Rev. F 04/08, pp 6-7.
   
   c. **Q-Pak Replacement**: Replace every 12 months or as necessary.
   
   d. **TOC Curve Check**: Perform after Q-Pak installation or when prompted by an LCD message. The TOC Curve Check can be initiated manually following replacement and flushing of the Q-Pak. The system automatically performs a TOC Curve Check daily, so if it is not started manually, it may be performed within the next 24 hours.
   
   e. **POD Pak Replacement**: Replace every 12 months or as necessary. A decrease in Milli-Q water flow rates may be due to a clogged POD Pak. The POD Pak should be replaced when it appears to be clogged.
   
   f. **RO Sanitization**: Perform every 12 months or when prompted to perform the RO Cl₂ cleaning. Cleaning the RO cartridge should only be performed when recommended by a Millipore Service Representative.
   
   g. **Inlet Strainer Cleaning**: Perform every 12 months, when prompted by an LCD message, or when a clog is suspected.
   
   h. **Flow Rate Calibration**: The Flow Rate Calibration should be done when the Q-Pak and/or POD Pak is replaced, when a sensor or major component is changed, or when volumetric dispensing is not accurate.
   
   i. **When performing the annual maintenance for the Direct-8 water system, perform the tasks in the following order:**
      
      i. Inlet strainer screen filter (located inside the attachment coming from the wall. Turn off the water at the main valve first.)
      
      ii. Progard Pak (located inside the Direct-8)
      
      iii. Q-Pak (located inside the Direct-8)
      
      iv. Tank Vent Filter (located on top of RO water tank)
      
      v. Final filter (at the water dispensing point)
      
      vi. TOC curve (instrument will automatically perform once a day)
      
      vii. RO sanitization (if not conducted in the last 12 months perform one during the annual maintenance)
      
      viii. Flow rate calibration (only if using the volumetric function on the instrument)

**PCR Workstation Hoods**

1. The PCR Workstation Hood provides a clean environment for setting up PCR reactions. Maintenance is designed to ensure proper laminar airflow and UV light sterilization conditions.

2. **Cleaning:**
a. Sterilization is conducted on a per use basis using the UV light feature of the hood.

3. **Maintenance:**

   a. Annually, hoods are checked by an external vendor contracted by the Laboratory. A service record sticker is placed on the hood by the vendor documenting the recertification. The annual recertification document is also maintained by the laboratory.

   b. The prefiter and HEPA filters are replaced on an as-needed basis when proper airflow is not being met. If airflow performance is in question, check the airflow with an anemometer. Take a measurement approximately 200 mm from the filter face within the cabinet. The airflow should be between 0.35 and 0.5 m/s (70 to 100 LFM). If the airflow value falls below this level, the fan speed can be increased to the high setting. If this does not bring the airflow within the specified limits, the prefiter should be changed and repeat the airflow check with the anemometer. If the airflow value is still below the recommended level, replace the HEPA filter and check the airflow again. If after replacing both filters and the airflow is still below the recommended flow rate, contact a service provider.

**Chemical Fume Hood**

1. The Labconco filtered fume hood enclosure is used to prepare liquid blood samples and to protect workers when using potentially dangerous chemicals and aerosols. These safety checks may be conducted in-house or by an approved vendor contracted by the laboratory.

2. **Cleaning:**

   1. Clean the hood on a per use basis.

3. **Maintenance:**

   1. Annually, the hood is checked by an external vendor contracted by the Laboratory. A service record sticker is placed on the hoods by the vendor documenting the recertification. Documentation of the annual recertification is also maintained by the laboratory.

   2. The filter is replaced as needed when proper airflow is not being met.

   3. If an issue with the performance of the hood is detected or suspected prior to the annual scheduled maintenance the airflow should be checked by measuring the face velocity of air drawn through the sash opening with an anemometer using the procedure below.

4. **Monitoring Airflow:**

   1. Using an anemometer, measure the face velocity with the sash down in the working position. A minimum of three readings taken across the working opening should average \( \geq 100 \text{ LFM} \) at maximum fan speed.

   2. If the average reading is \( \leq 100 \text{ LFM} \), change the pre-filter and re-check the airflow rate. If the average reading is still \( \leq 100 \text{ LFM} \), the carbon filter likely needs to be changed. If the average reading is still \( \leq 100 \text{ LFM} \), contact the hood vendor for service. See materials and equipment below for filter ordering information. Label the hood with the date of filter(s) change.

END OF DOCUMENT
I. Procedures for the Maintenance and Performance Checks of Pipettes QAS 10.2.1.8, Qiagen EZ-1 Robots, Nimbus Liquid Handling Robots, and the Versa 1100 QAS 10.2.1.6.

A. Pipettes

1. The Biology unit maintains an inventory of pipettes that are used in the laboratory for testing. Each pipette is calibrated annually by the manufacturer, Ranin. Each pipette must meet the manufacturer's tolerance for calibration to be considered passing. The calibration and maintenance certificates for each pipette are retained in the Biology Unit's Calibration and Maintenance Log.

B. Qiagen EZ-1 Robots

1. Materials
   a. Qiagen BioRobot EZ-1
   b. EZ-1 DNA Investigator Card v1.0
   c. DNA Investigator Kit cartridges (Cat. No. 952034)

2. Routine Maintenance
   a. Prior to the first run of the day and after completing each run, the piercing unit should be cleaned using a lint-free tissue dampened with 70% ethanol. To access the piercing unit, select option 3 (Clean Piercing Unit) from the Instrument Dialog display.
   b. The cleanup of the EZ1 robot should be performed at the end of each run. This consists of wiping the workstation tray, worktable and its racks with 70% ethanol followed by deionized water. Wipe the O-rings of the tip adapters, if dirty, with a Kimwipe. Important: Never use bleach on the EZ1 Robots.

3. Semiannual Maintenance
   a. Greasing the O-rings is needed to maintain good contact between tip adapters and filter tips, and to also prevent liquid from leaking from the tips. Lightly grease the O-rings of the pipette unit using the supplied silicone lubricant. Apply a small amount of silicon grease to gloved fingertips, then transfer the grease to the surface of the O-rings and use a tissue to wipe off any excess on the O-rings and tip adapters. Note: Excess grease can affect the performance of the EZ1 Robots. Record the routine maintenance on the Inspection Record (BIO.5.QAQC.04).

4. Performance Checks (QAS 10.2.1.6):
   a. The EZ-1 robots are considered critical instruments and will be performance checked annually by the vendor, per QAS 10.2.1.6.
   b. If the instrument should undergo repair, calibration, or a service by the vendor a performance check will be conducted (QAS 10.4.1.2). The performance check will be conducted using NIST-traceable samples or previously characterized samples. The performance is verified when an adequate amount of human DNA suitable for typing procedures is quantified using the qPCR procedure. If any sample does not show adequately recovered human DNA, the test will be repeated. If the robotic extraction fails a second performance check, the instrument will be removed from service until inspected by a service engineer from the manufacturer. The instrument must pass a performance check prior to being returned to service.
   c. Documentation of all performance checks are maintained electronically on the Biology Unit's network folder and/or as a hardcopy with the instrument maintenance log.

C. Qiagen EZ-1 Advanced XL Robots

1. Materials
   a. Qiagen BioRobot EZ-1 Advanced XL
   b. EZ-1 Advanced XL DNA Investigator Flip Cap Card
   c. DNA Investigator Kit cartridges (Cat. No. 952034)

2. Routine Maintenance
   a. Prior to the first run of the day and after completing each run, the piercing unit should be cleaned using a lint-free tissue dampened with 70% ethanol. To access the piercing unit, press "2-Man" to select the manual function, then select option 3 (Clean Piercing Unit) from the Instrument Dialog display.
   b. The cleanup of the EZ1 XL robot should be performed at the end of each run. This consists of wiping the workstation tray, worktable and racks with 70% ethanol followed by deionized water. Wipe the O-rings of the tip adapters, if dirty, with a Kimwipe. **Important: Never use bleach on the EZ1 Robots.**

3. Semiannual Maintenance
   a. Greasing the O-rings is needed to maintain good contact between tip adapters and filter tips, and prevent liquid from leaking from the tips. Lightly grease the O-rings of the pipette unit using the supplied silicone lubricant. Apply a small amount of silicon grease to gloved fingertips or alternatively, to the end of a filtered-tip. Transfer the grease to the surface of the O-rings and evenly distribute the silicon. Use a tissue to wipe off any excess grease on the O-rings and tip adapters. Note: Excess grease can affect the performance of the EZ1 XL Robots. Record the routine maintenance on the Inspection Record (BIO.5.QAQCF.04).

4. UV Decontamination: Ensure that the EZ1 XL's door is closed. In the main menu, press "1-UV" to select the UV light function. Use the number keys "0" through "9" to set the duration of the decontamination time to 30 minutes (Note: The minimum time is 20 minutes and the maximum time is 60 minutes). Press "START" to switch on the UV lamp. After UV decontamination is finished, the main menu appears.

5. Performance Checks (QAS 10.2.1.6):
   a. The EZ-1XL robots are considered critical instruments and will be performance checked annually by the vendor, per QAS 10.2.1.6.
   b. If the instrument should undergo repair, calibration, or service, a performance check will be conducted after (QAS 10.4.1.2). The performance check is conducted using NIST-traceable samples or previously characterized samples. The performance is verified when an adequate amount of human DNA suitable for typing procedures is quantified using the qPCR procedure. If any sample does not show adequately recovered human DNA, the test will be repeated. If the robotic extraction fails a second performance check, the instrument will be removed from service until inspected by a service engineer from the manufacturer. The instrument must pass a performance check prior to being returned to service.
   c. Documentation of all the performance checks are maintained electronically on the Biology Unit's network folder and/or as a hardcopy with the instrument maintenance log.

D. Versa 1100

1. Materials
   a. Versa 1100 with Versaware Software v3.6.72
   b. Deionized water
   c. Microcide SQ Broad Spectrum Disinfectant

2. Routine Maintenance: Before each run perform the following...
a. Inspect the tubing for the reagent drop reagents for crystallization or potential contaminants
b. Clean the deck with Microcide
c. Dispose of tip waste

3. The following Maintenance should be performed every four months

a. The volume check and calibration

i. Calibration of Syringe Pumps

   a. Open Aurora Station by selecting Tools > Aurora Station from the Menu bar.

   b. Initialize the robotic arm by pressing the button between the X and Y axes.

   c. Manually place a tip on the pipette closest to the opening. Use the 50uL tip for calibrations below 50uL and the 1000uL tips for larger volumes.

   d. Switch to the Syringe Pump tab from the Aurora Station Main Menu.

   e. Select 4 x 1000uL in the Syringe Pump Type and Click Initialize.

   f. Open the calibration data table by clicking the dropper icon.
g. In the Volume Pump Calibration window add "1000" for Air Gap Aspiration and "100" steps in the Sample Aspiration window. Keep the Time Delay at 7 seconds.

h. Click Send. The instrument will draw in an air gap and delay for 7 seconds. During the 7 seconds, place a tube of sterile water under the tip. After the 7 seconds, the instrument will aspirate 100 steps worth of volume. A second 7 second delay will occur. Place a pre-tared weigh boat under the pipette. A volume of water will be dispensed into the weigh boat. One microliter weighs one milligram. Weigh the boat to confirm that the volume is correct.

i. If the volume is not correct, replace the old value with the new weight value in the calibration table. Click Apply to save the volume.

j. Open the calibration data table by clicking the dropper icon
k. Using the same process as above, check the whole range of steps from 200 to 38,000.

l. Enter the date of the new calibration under Scale.

ii. **Reagent Drop Calibration**

   a. Select **Tool > Aurora PWM Pump from the Menu Bar**

   b. In the PWM Pump Window click on the "C" button to switch to pump control mode.
c. Initialize the pump using the **Initialize** button.

d. Ensure that "Dispensing" is selected

e. Click the **syringe** button which switches the pump into pulse mode of calibration in micro-seconds (us).

f. Enter 50,000 into volumes window and click the **button**.

g. Type in "0" for all other values.

h. Highlight the valve of interest for calibration.

i. Open the calibration data table by clicking the **dropper** icon.
j. Select the correct valve under the Aspiration section

k. Click on the first row where the Valve is "2" on the Pump Calibration window. Ensure that the valve "2" row is also selected in the PWM Pump window. The Repeat Cycles listed on PWM Pump must match the Cycles listed in the row selected in the Pump Calibration window.

l. Place a pre-tared weigh boat under the reagent drop pins and click **Dispense**.

m. Weigh the boat and add the new weight/volume in the table.

n. Using the same process as above check the volume for each cycle of valves 2 and 5.

b. Clean the exterior with a 10% bleach solution and water.

4. **Annual Maintenance**

   a. Annually, check the computer hard drive for errors and optimize using system tools:

      i. Complete a Disk Cleanup and Disk Defragmentation by selecting from the PC Start Menu (All Programs > Accessories > System Tools > Disk Cleanup or Disk Defragmenter.)

      ii. Record the disk cleanup and defragmentation on the Inspection Records (**BIO.5.QAQCF.04** & **BIO.5.QAQCF.03**).

   b. **Annual Performance Check (QAS 10.2.1.6):**

      i. The Versa 1100 Liquid Handling Robot is considered a critical instrument and will undergo an annual performance check by the vendor, per **QAS 10.2.1.6**.

      ii. Records of the vendor's performance check will be maintained in the instrument maintenance log and/or electronically on the Biology Unit’s network folder.

   c. **Performance Checks after repair, service, calibration (QAS 10.4.1.2):**

      i. Should the instrument undergo repair, calibration, or service the robot will be performance checked after. (QAS 10.4.2.1).

      ii. The in-house performance check entails using NIST-traceable samples containing both non-sperm and sperm DNA. The sample will be differentially digested on the Versa robot along with a reagent blank. The sample will be taken through the DNA testing process and an adequate amount of DNA should be obtained, and the correct profiles must be obtained with minimal to no carryover of non-sperm DNA in the sperm fraction.
iii. If the results fall outside these limits, the check will be repeated once. If the second test fails, the instrument will be removed from service and the manufacturer will be contacted for service.

iv. Documentation of the performance check is maintained in the instrument maintenance log and/or electronically on the Biology Unit’s network folder.

5. References:
   a. Operation Manual Versa 1100

E. Hamilton Nimbus Liquid Handling Robot

1. Materials
   a. Hamilton Nimbus Liquid Handling Robot
   b. Nimbus Maintenance program
   c. Deionized water
   d. Microcide SQ Broad Spectrum Disinfectant

2. Weekly Maintenance: Open the Nimbus Maintenance program from the toolbox icon on the Desktop. Select Weekly under Maintenance Type, then click Run Maintenance. Perform the requested onscreen tasks in sequence and check off upon completion.

3. Clean deck and carriers.

4. Check condition of carriers and other devices.

5. Empty and clean Tip Waste/ Liquid Waste. Perform as needed. Access the waste container area by moving the gantry by hand to the left. Remove and empty the tip waste bin, and return it to the deck. Verify waste bin is seated properly back into position before continuing.

6. Clean each channel: stop disk, o-ring, and tip eject sleeve. Using Kimwipes moistened with deionized water, wipe down the tip eject sleeve (the black outer casing) of the pipette head for each channel.

7. Gently pull up on each channel’s tip eject sleeve to access the o-ring and proceed to wipe the o-ring and stop disk. The stop disk is the very bottom part of the pipette head.
8. **Clean the side covers**

9. **Check the tightness of the pipette channels.** Ensure the Nimbus is powered on and remove the tip eject plate from the waste block for the remaining tasks. Click **Continue** to allow the software to perform this task.

10. **Check the cLLD** With tip eject plate still removed, click **Continue** to allow software to perform this check. When complete, replace tip eject plate on the waste block and click **OK**. Close out of the weekly maintenance, and finally, **Close** out of the channel maintenance.

11. **Annual Maintenance**

   a. Annually, back-up critical files, check the computer hard drive for errors and optimize using system tools:

      i. Back-up critical files and Log on as administrator.

      ii. Complete a Disk Cleanup and Disk Defragmentation by selecting from the PC Start Menu (**All Programs > Accessories > System Tools > Disk Cleanup or Disk Defragmenter.**)

   b. Record the disk cleanup and defragmentation on the Inspection Records (**BIO.5.QAOCF.04 & BIO.5.QAOCF.03**).

12. **Annual Performance Check (**QAS 10.2.1.6**):**

   a. The Nimbus Liquid Handling Robot is considered a critical instrument and will undergo an annual performance check by the vendor, per **QAS 10.2.1.6**.

   b. Records of the vendor's performance check will be maintained in the instrument maintenance log and/or electronically on the Biology Unit’s network folder.

13. **Performance Checks after repair, service, calibration (**QAS 10.4.1.2**):**

   a. Should the instrument undergo repair, calibration, or service the robot will be performance checked after. (**QAS 10.4.2.1**).

   b. The in-house performance check entails using a set of previously extracted samples (or NIST-traceable reference samples) that will be set up by the robot in a checkerboard formation with blanks staggered between each sample. This Nimbus prepared plate will be quantified using a qPCR assay. Performance of the system is considered verified when the following results are returned:

      i. Suitable qPCR calibration values are obtained from the expected wells.

      ii. The DNA concentrations pipetted by the Nimbus robot are comparable to previous quantified samples pipetted by the robot and/or hand pipetted results.

      iii. If the results fall outside these limits, the check will be repeated once. If the second test fails, the instrument will be removed from service and the manufacturer will be contacted for service.

   c. Documentation of the performance check is maintained in the instrument maintenance log and/or electronically on the Biology Unit’s network folder.

END OF DOCUMENT
I. Procedure for the Maintenance and Performance Verification of the ABI 7500 Real Time PCR Instrument and ProFlex PCR System. QAS 10.2.1.3 and QAS 10.2.1.4

II. ABI 7500 with HID Real-Time PCR Analysis Software

1. References:

2. Materials:
   a. Applied Biosystems 7500 Real Time PCR System
   b. HID Real-Time PCR Analysis Software Version 1.2
   c. 96-well optical plates (Cat number 4306737)
   d. MicroAmp optical adhesive film (Cat number 4311971)
   e. 7500 Real Time System Spectral Calibration Kit (Cat number 4349180)
   f. PowerQuant™ Calibration Kit (Cat. #DS1221)

3. Routine Maintenance:
   a. Cleaning: The 96-well sample block may be inspected prior to runs. Follow the directions for Thermal Cycler Well Inspection found in the ABI 7500 Installation and Maintenance guide (pp. 112-117).
   b. Function Test: Operation of the system hardware interfaces may be assessed prior to the run. This includes USB, CCD, Filter Wheel, Shutter, Lamp, and Thermal Cycler. Test the functions of these computer and hardware interfaces by running the diagnostic test in the HID Real-Time PCR Analysis Software: go to Instrument > Function Test>All Tests. This will give a Pass/Fail result for each component.

4. Monthly Maintenance:
   a. Prepare a new Background Calibration document in the HID software. Go to Instrument>Instrument Maintenance Manager, select Background from the left panel, and click the "Start Calibration" button. Follow the on-screen prompts and record its completion on the Inspection Record Form for the PCR Amplification Room BIO.5.QAQCF.03.

5. Semiannual Maintenance:
   a. Annually the laboratory performs the ROI, optical, and pure dye calibrations on the 7500. These calibration checks are also be performed by the vendor once a year, with approximately six months between the vendor and laboratory performed maintenance.
   b. Instructions: Go to Instrument>Instrument Maintenance Manager, select the respective calibration from the left panel in succession: ROI, Background, Optical, and Dye(s), and click the "Start Calibration" button. Follow the on-screen prompts for each calibration for both system and custom dyes. Refer to the PowerQuant™ System Technical Manual (pp. 5-15) for pure dye calibration information and instructions. Document these actions on the Inspection Record Form BIO.5.QAQCF.03.
   c. Check the computer hard drive for errors and optimize using system tools:
      i. Back-up critical files and log in as "Administrator." Perform a Disk Cleanup and Disk Defragmentation by navigating to Start Menu> All Programs > Accessories > System Tools > Disk Cleanup or Disk Defragmenter.
ii. Record the disk cleanup and defragmentation on the Inspection Record Form for the PCR Amplification Room **BIO.5.QAQCF.03**.

6. Annual Performance Check (QAS 10.1.2.4):

   a. The 7500 instruments are considered critical instruments and must undergo an annual performance check, per QAS 10.2.1.4. The 7500 instruments are performance checked by an Applied Biosystems service engineer. The performance check includes a check of the background, ROI, optical, pure dye spectral calibrations, and temperature verification. Documentation of the performance check are maintained in the maintenance log located next to the instrument and/or electronically in the Biology Unit's network folder.

7. Performance Check following Service, or Repair (QAS 10.4.1.4):

   a. A performance check is performed following repair or service.

   b. The performance check uses NIST-traceable samples or previously characterized samples. These samples are quantified on the serviced 7500 and the results are compared to instrument data generated prior to the service call. The data must show appropriate amplification in every well as indicated by the Internal Positive Control and each sample should provide appropriate quantitative information respective to the source sample. That is, a known male DNA sample is expected to provide both male and total human DNA results, a known female DNA sample is expected to provide only a total human DNA result, and both must be suitable for later PCR typing procedures.

8. Any additional 7500 instrument purchased must undergo a performance verification prior to use with casework samples. **QAS 10.4**

9. Records

   a. Records of performance checks are maintained electronically on the Biology Unit's network folder or in hard copy form with the instrument.

III. ProFlex PCR System

1. References:

2. Materials:

   a. VeriFlex™ 96-Well Temperature Verification Kit (TVK) for 0.2mL Veriti System, 9 channel (Cat. #4377669)
   b. USB flash drive

3. Annual Performance Check (QAS 10.2.1.3): Annually the ProFlex Thermal Cyclers undergo a performance check consisting of the following tests:

   a. System Performance, Self Verification Test. This feature is used to check the instrument hardware which includes testing the block, heated cover, and other components.

      i. From the Home screen, touch **Settings**.

      ii. Select **Maintenance & Services**.

      iii. Select **Self Verification Test**.

      iv. Select **Start Test**.

      v. The test may take up to 10 minutes. When the test is complete, results are displayed in a report.

      vi. Plug a USB flash drive into the front port of the ProFlex PCR System. Select **Export** to transfer the test report to a USB drive.

      vii. Print a copy of the report and add it to the Thermal Cycler Maintenance binder in the PCR room.

   b. Block Verification Test

      i. From the Home screen, touch **Settings**.
ii. Select **Maintenance & Services**.

iii. Select **Block Verification Test**.

iv. Select **Verify Block Temperature**.

v. There are three test types to choose from:

   a. **Heated Cover**
   
   b. **Temperature Verification**
   
   c. **Temperature Non-Uniformity**.

vi. Choose a test to perform and then touch **Next**.

vii. Connect the TVK.

   a. Connect the free end of the ribbon cable from the multiprobe module to the input connector port on the digital thermometer.
   
   b. Connect the round 8-pin DIN receptacle end of the communication cable to the thermometer communication port.
   
   c. Connect the other end of the communication cable (9-pin) to the USB adapter unit, and plug the USB end into the port in the back of the instrument.
   
   d. When placing the multiprobe module onto the sample block in the position specified by the on-screen prompts, ensure that the ribbon cable leads straight out from the module and lies flat.
   
   e. Close the heated cover and pull down the lever.
   
   f. Turn the digital thermometer on and allow it to start up.
   
   g. **Heated Cover Test:** This test determines if the heated cover holds temperature at 105 ± 3°C.

      1. Place the multiprobe module in the center of the sample block so that the middle 2 zones are covered.
      
      2. Close the heated cover and touch **Start Test**.
      
      3. The test takes approximately 6 minutes to complete.
      
      4. At the end of the test, the screen will show if the heated cover test passed or failed.
      
      5. Touch **Export** to save the test report to a USB drive.
      
      6. Print a copy of the report and add it to the Thermal Cycler Maintenance binder in the PCR room.

   h. **Temperature Verification Test:** This checks the temperature of the sample block against the specifications for temperature accuracy. It does this by measuring sample well temperatures at two set points, 45°C and 85°C. To pass the test, the six sample testing zones must be within ±0.25 ºC of the set points.

      1. Follow the prompts on the screen, making sure to move the multiprobe module to the next testing zone after each reading, with three readings in all.

      | Sample Testing Zones | Well Position of Probe Tip #1 |
      |----------------------|-----------------------------|
      | 1 & 2 (leftmost)     | A1                          |
      | 3 & 4 (center)       | A5                          |
      | 5 & 6 (rightmost)    | A9                          |

      2. Each reading may take approximately 15-30 minutes for each testing zone.
      
      3. At the end of the test, the results are displayed and if the test passed or failed.
4. Select **Export** to transfer the test report to a USB drive.

5. Print a copy of the report and add it to the Thermal Cycler Maintenance binder in the PCR room.

   i. **Temperature Non-Uniformity Test (TNU):** This checks the temperature uniformity of the sample block by measuring temperatures at 24 well locations. To pass the test, all six sample testing zones must be within ± 0.5ºC of each set point temperature (95ºC and 60ºC) no later than 30 seconds after the set point temperature is changed.

      1. Follow the prompts on the screen, making sure to move the multiprobe module to the next testing zone after each reading, with three readings in all. Use the same testing zones as listed above under Temperature Verification Test.

      2. Each testing zone reading takes approximately 10 minutes to complete.

      3. At the end of the test, the results are displayed and whether the test passed or failed.

      4. Touch **Export** to save the test report to a USB drive.

      5. Print a copy of the report and add it to the Thermal Cycler Maintenance binder in the PCR room.

   c. **Cycle Performance Test:** Checks the cycle performance of the instrument.

      i. From the Home screen, touch **Settings**.

      ii. Select **Maintenance & Services**.

      iii. Select **Block Verification Test**.

      iv. Select **Verify Cycle Performance**.

      v. Follow the screen prompt to insert an empty plate onto the sample block.

      vi. Close the heated cover and lever and touch **Start Test**. The test takes around 10 minutes to complete.

      vii. At the end of the test, the screen will display the results.

      viii. Touch **Export** to save the test report to a USB drive.

      ix. Print a copy of the report and place it into the Thermal Cycler Maintenance binder in the PCR room.

   d. If the instrument fails any of these tests, repeat the test one more time. If the instrument fails again, remove the instrument from service and have the instrument serviced by a qualified service engineer.

4. Performance Check Following Service or Repair (QAS 10.4.1.4):

   a. NIST-traceable samples or any previously characterized samples may be used to performance check a thermal cycler that has undergone service or repair. The performance check monitors for appropriate amplification of human DNA using standard conditions for a current PCR typing kit and the resulting data is compared to previously amplified samples. Performance is verified when all loci within the typing kit provide adequate typing signal and all typing results are correctly called. If any of these elements fail, the test may be repeated once. If the instrument fails the second performance check, the thermal cycler is to be removed from service until inspected and re-qualified for use by a service engineer. Results of performance checks are maintained in the Biology Unit's network folder and/or in hard copy form with the instrument maintenance log.

5. Any additional ProFlex thermal cycler purchased must undergo a performance verification prior to use with casework samples. **QAS 10.4**

   3. 3500 and 3500xL Genetic Analyzer with Data Collection Software 3 Quick Reference (Pub no. 100026299 Rev. A)

2. Materials:
   1. AB 3500 Genetic Analyzer
   2. Dell computer with 3500 Series Data Collection Software 3
   3. 3500 Capillary Array (8 cap. 36cm uncoated)
   4. Anode Buffer, 3500 Series
   5. Cathode Buffer, 3500 Series
   6. Cathode buffer container septa
   7. POP-4 Polymer for 3500/3500XL Genetic Analyzers
   8. Conditioning Reagent, 3500 Series
   9. Kimwipes
   10. Water: ultrapure, deionized
   11. 30cc syringe

3. Routine Maintenance:
   1. General maintenance of the AB 3500 Genetic Analyzer is scheduled through the Data Collection Software. Additional instrument upkeep will rely on the analyst being vigilant in maintaining a clean environment and spotting any anomalies within the hardware. The “Maintenance Notifications” section of the Dashboard displays scheduled tasks for the analyst to perform. Click the green checkmark to indicate the task as completed.

   2. To access the Maintenance Wizards menu from the Dashboard screen, click the "Wizards" button located on the top right.

</table>

**Semiannual Maintenance**

1. Check the computer hard drive for errors and optimize using system tools:
   1. Back-up critical files and Log on as administrator. Complete a Disk Cleanup and the Disk Defragmenter by selecting from the PC Start Menu ([All Programs > Accessories > System Tools > Disk Cleanup or Disk Defragmenter](#)).

2. Check the database space:
   1. In the tree pane of the Data Collection Software, select GA Instruments>Database Manager check the database status section. The Data Collection software will prompt the user when it is 70-75% full.
   2. If there is insufficient space, ensure that a copy of each run is on the laboratory's internal network drive, delete the sample file data from the hard drive and empty the contents of the Recycle Bin.
   3. Record the quarterly maintenance on the PCR Inspection record form ([BIO.5.QAQCF.03](#)).

**Performance Check**

1. The AB 3500 is considered a critical instrument and will undergo an annual performance check, per QAS 10.2.1.7.
2. If the instrument should undergo a substantial move, repair, calibration, or service by a vendor, a performance check will be conducted after (QAS 10.4.1.3).
3. Should the software associated with the instrument undergo a significant change/upgrade, a performance check will be performed.
4. The performance check will use amplified product produced either from a NIST-traceable sample set, any previously characterized samples, or from amplification controls/internal size standards for comparison. The samples will be analyzed according to standard operating protocol using the current analysis software. The performance check must show that expected typing results were obtained and that the relative signal intensity did not significantly change when compared to either prior performance check data or to data prior to the repair, service or the move.
5. A record of the performance check will be maintained on the Biology Unit’s network folder and/or in hardcopy form with the instrument log.

**Preventative Maintenance**

1. Service is provided annually by the vendor. A copy of the Field Service Report is stored with the CE maintenance log located next the instrument and/or electronically on the Biology Unit's network folder.

**Contra Costa County**  
**Office of the Sheriff**  
**FORENSIC SERVICES DIVISION**  
**Criminalistics Clerical Manual**

**APPROVED BY:** Debbie McKillop and Danielle Roberts

**ASCLD-LAB:**

**REVISION DATE:** 7/20/2015  
**NUMBER:** CLER.CRIM.07 - Confidential Cases  
**RELATED ORDERS:**
I. Policy: ARIES is considered the initial distribution for laboratory reports for all agencies. Agencies not able to obtain reports via ARIES will receive their reports by alternate methods.

A. Most laboratory reports are distributed electronically via ARIES. Reports are available to agencies and the District Attorney's Office within 24 hours after they have been administratively reviewed.
   1. Agencies not able to receive reports via ARIES will receive their reports by mail, email or fax. See CLER.DAT.13 for a list of agencies that currently have access to Crime Lab reports via ARIES.
   2. When copies of reports are released after the initial distribution (for non-ARIES distribution) the date and name of the agency receiving the report must be recorded in the test record.
   3. Non-ARIES distribution will be documented using the LIMS Activity Log. The date and agency receiving the report must be recorded.

B. Confidential Reports
   1. Physical copies of confidential reports should be placed in a manila envelope and stamped "confidential." This alerts the clerical staff of the urgency & confidentiality of the report.
   2. Electronic copies are kept in LIMS. Sufficient notes should be kept in the Case Synopsis. A case message should be added to alert users in any tab that the case information is confidential.
   3. The initial release of reports can be prepared by a designated clerical staff member, or by the supervisor of the unit. The copies are usually placed into an addressed envelope and sealed. The envelope will be distributed to the requester or to a representative from the requesting agency.
   4. If multiple requests exist, each individually completed report should be placed in a manila envelope. (Same as steps 1 and 2).
   5. Confidential reports are filed according to QA.07.

C. Release of Rush Reports
   1. Requests may be considered for "rush" analysis if there is a pending court date (court rush) or a need to keep a suspect in-custody (investigative rush). When entering the request, enter this information in the Notes section of the request. This information can also be displayed in the Case Message box, which will appear on every screen. Additional information such as the requester's name and email address, phone number, and fax numbers for sending the final report to can be added to either field.
   2. Rush analysis may require emailing or faxing the final report to the requesting party, i.e. the investigating officer or District Attorney.
   3. The method of release, the name of the recipient, name or initials of the staff member releasing the reports, and the date will be documented in the case record. (Example: Request 001 provided via email to Detective Smith by CM 9.25.18). This can be done by added a note in the Case Synopsis under the Case Info tab in LIMS.
   4. Release rush reports as soon as possible as they are time sensitive.

END OF DOCUMENT
I. Case File

Filing
I. Policy: The following procedures will be followed for subpoena acceptance and distribution.

A. General
   1. Subpoenas are generally sent to the Criminalistics Lab via fax or email. The subpoenas are received into the SummitLab e-mail box or paper copies are placed in the subpoenas to be served file.
   2. Prior to subpoena service or rejection, consult the applicable unit calendars for staff availability.
   3. Associated lab report numbers are required for all personally served subpoenas. If not indicated on subpoena, lab report numbers can be researched in LIMS by cross-referencing the agency with case file number, or defendant name. If information does not match, the subpoena must be rejected.
      a. Paper subpoenas will be scanned into a .pdf format, so they can be electronically stamped and returned.
      b. The subpoena is then opened in Adobe and an information "stamp" is added electronically. This will allow for the addition of pertinent information to the pdf which is sent back to the DA's office. An electronic copy of the rejected subpoena will be kept on the shared drive, until after the trial date on the subpoena.
         i. To set up Adobe Pro for use of electronic "stamps"
            1. Run Adobe Pro
            2. Click the Comments toolbar.
            3. Click on the stamp icon with the pull-down menu triangle next to it. Step 1 to 3 need to be done once for each login on each computer. They will create the proper folders for steps 4 through 6.
            4. Open explorer to: C:\Users\XXXXUSERXXXX\AppData\Roaming\Adobe\Acrobat\11.0\Stamps\ NOTE: replace XXXXUSERXXXX with your login name
            5. Open explorer to: G:\SupSvcsBur\Glacier Forensic Services\LAB\MUIR\Declarations
            6. Copy the stamp .pdf files in the declarations folder to the stamps folder. (At this time there are 3). Steps 4 through 6 will set up the stamp definitions for each login.
         ii. To set up Adobe Pro as the default:
            1. Right click on any document and choose "Open with"
            2. Click "Choose Default Program" from list
            3. Click on "Adobe Acrobat Pro"
            4. Check box "Always use this selected program to open this kind of file"
         iii. To use the electronic "stamp":
            1. Open the document you want to stamp in Adobe Acrobat Pro (do not use Reader).
            2. Click the Comments toolbar.
            3. Click on the stamp icon with the pull-down menu triangle next to it.
            4. Select the stamp you want to use from the previews.
            5. Click on the document where you want the stamp to appear.
            6. If there are any form fields in the stamp to fill in, Adobe will prompt you for those values.
B. Preliminary Hearing/Trial

1. For electronic subpoenas, a copy may be emailed directly to the criminalist at or near the time of receipt. The date and time of the email that is forwarded will be considered the service date. **A proof of service is not required by our DA's office.**

2. If criminalist is unavailable, an electronic stamp may be added to the pdf through Adobe. Indicate dates criminalist will be unavailable and reason (i.e. training or pre-approved time off). Return the electronic version of the subpoena to DA’s Office, retaining a copy in the Summit Lab mailbox until after the trial date on the subpoena.

3. To Serve a Declaration in Outlook
   a. Navigate to SummitLab Inbox
   b. Open Subpoena Email
   c. Open attachment in Adobe Pro
      i. Click "Comment"
      ii. Click "Stamp Picture"
      iii. Click "CCC Subpoena Return Stamp Extended"
      iv. Click Cancel for the Identity Set Up
      v. Place the stamp on the pdf and click for placement of electronic stamp
         1. The following will pop up
            1. Begin Date
            2. End Date
            3. Analyst's Name

4. Saving electronic declarations or rejections:
   a. Save in Summit Lab Mailbox
      i. Choose Declarations folder
      ii. Change file name to: criminalist last name.subpoena date.defendant last name

5. Faxing electronic declarations or rejections:
   a. Choose File
   b. Click Print
      i. Choose Printer "Fax Via Copier"
   c. Click Print
      i. Type Recipient's Name (Located on subpoena)
      ii. Fax Number (Located on subpoena)
      iii. Click "OK" to send

C. Juvenile

1. Subpoenas for Juvenile hearings are served as noted above for trials.

D. Business Records

1. Business Records testimonies are done by a qualified criminalist currently working in the same section as the unavailable criminalist.

2. Alternately, an **Official Record** testimony can be provided by the Supervisor or Manager as Custodian of Records.
E. Public Defender/Private Attorney

1. Public defender/private attorney subpoenas are expedited. Determine if the criminalist has already been subpoenaed for the case by the District Attorney. If so, inform criminalist. Subpoena will automatically be served.

2. Frequently, public defender/private attorney subpoenas do not indicate the associated lab report number. This must be determined before serving the subpoena. This information is obtained by calling the public defender subpoenaing the criminalist.

3. The individual serving the subpoena must sign and date the Proof of Service, and send the Proof of Service back to the public defender’s or private attorney’s office.

4. The subpoena is delivered to the criminalist by scanning it into a pdf and emailing it to them.

5. If the subpoena is rejected or requires a declaration, it will be scanned into a pdf and saved in the Summit Lab mailbox declaration folder.

F. Grand Jury Subpoenas

1. These subpoenas are also expedited. If the criminalist is available and the associated lab report numbers are provided, the subpoena can be served. The individual serving must date and sign the Proof of Service, and return the Proof of Service via inter-office mail or via FAX to the appropriate DA.

2. A copy of the subpoena and proof of service is delivered to the criminalist by scanning into a pdf and emailing it to them.

3. If the subpoena is rejected or requires a declaration, it will be scanned into a pdf and kept electronically in the Summit Lab mailbox declaration folder.

G. Subpoenas for Former Employees

1. The laboratory is not responsible for the court appearance of former employees. If the laboratory has the contact information, it is provided to the attorney sending the subpoena.

2. Should the laboratory receive a subpoena for a former employee for whom contact information is not available, the subpoena is returned to the DA’s office. A declaration is sent to the DA’s office and retained in the Summit lab mailbox declaration folder.

H. Miscellaneous:

1. Should a criminalist be summoned for jury duty, the subpoena is returned to the DA with a declaration indicating this. Subpoenas are rejected only for the obligatory date or dates indicated on the jury summons. The criminalist informs the lab of the status of this obligation.

2. Prior to requesting vacation time off, a criminalist will check his/her subpoenas that have already accepted. If there are accepted subpoenas for the requested vacation dates, it is the criminalist's responsibility to clear these subpoenas with the DA.

3. Should a criminalist be scheduled for training after subpoenas have been accepted for the training dates, the subpoena clerk will return the subpoenas to the DA, including a declaration to this effect. Criminalists will be responsible to check all accepted subpoenas for that date range and send them back to the clerks to issue declarations.

4. Electronic subpoenas will be delivered via e-mail to analysts as close to time of receipt as possible. Paper subpoenas may be delivered to criminalists via scan to pdf and then e-mail.

END OF DOCUMENT
I. Policy: The laboratory complies with all legitimate Discovery and Subpoena Duces Tecum requests. These requests typically pertain to documents related to the analysis of samples or records kept in the normal course of Laboratory business. Please see the Division Manual (FSD.45) for more information on handling discoveries and Subpoena Duces Tecum.

A. Basic and Extensive Discoveries: All criminal discoveries are routed to the Forensic Services Division via the District Attorney's Office. Discoveries for Civil, SDT's or other official government/governing agency such as requests from state licensing boards are not routed via the DA's office however the defined tracking procedure must be followed.

1. A basic discovery is a pre-set discovery packet. A basic discovery is typically comprised of a copy of the report and notes.

2. An extensive discovery is not a pre-set package. It may be a request for more detailed documentation than the basic discovery packages. This may include a copy of the chain of custody for the evidence, instrument maintenance and calibration logs.

3. If a discovery is requested by a Public Defender or Defense Counsel, advise these parties to submit their request to the DA's office.
   a. The DA's office will review all discovery requests for relevance.

4. Discoveries are requested and completed for the District Attorney's office. The DA's Office will disseminate copies to the entitled parties.

5. Discovery requests are typically received as a FAX or email.
   a. The clerical staff will open a discovery request in LIMS, scan and attach the request letter.
   b. The official lab report and case notes will be scanned into LIMS.
   c. The clerical staff will notify the unit supervisor or designee that a discovery request has been initiated.
   d. When provided with sufficient notice and staffing levels permit, discoveries should be completed by the expected due date.
   e. Lab staff will compile the requested records, only if the lab is capable of providing such documents.
      i. Documents may be added to LIMS as images. These images can be marked "Send To iResults", and then will appear on ARIES, where the District Attorney can retrieve this information.
      ii. Documents, data, photos, etc. may also be compiled on a CD/DVD.
   f. Lab staff will draft complete and admin review the requests.

6. Most discovery requests will be made available electronically through ARIES for the District Attorney to retrieve the records. ARIES has a 24 hour delay, after the request is Administrative Reviewed in LIMS, before the records will be accessible to be retrieved by the District Attorneys.
   a. Staff may also email, FAX or mail completed discovery materials to the DA's Office.
   b. Note: ARIES can NOT be used to distribute discovery materials associated with a restricted or confidential case.

7. If ARIES can not be used to release documents, or if materials are not amenable to be uploaded in LIMS (such as CD/DVDs), they may be released to an individual.
   a. A receipt of released items must be obtained and imaged into the discovery request.
i. For physical reports, the receipt should be filed as an administrative document with the original report.

ii. For electronic reports, the receipt should be scanned as a Case Attachment. For documents kept outside of LIMS (such as CD/DVDs) a note should be added to the Case Synopsis under the Case Info tab.

8. The original discovery request letter is filed with the original lab report as an "administrative document". The lab number, date and initials are written on upper right-hand corner of request letter. For electronic report and notes, the letter is scanned as a Case Attachment.

9. Clerical staff will attach the following to the case file as administrative documentation. If they can be scanned, they can be added as a Case Attachment. Physical files kept outside of LIMS (such as a CD or DVD) should be noted and the location described in the Case Synopsis under the Case Info tab.

   a. **The original discovery request letter**
   
   b. **The receipt for discovery materials (if applicable)**
   
   c. **Electronic data saved on CD/DVD**
   
   d. Documents NOT part of the report and notes, unless they were:

      i. Uploaded as images to LIMS

B. **Discoveries for Official Governing Agencies**

1. Discoveries may also be requested by official governing/governmental agencies (i.e. state licensing boards). These requests must be received in writing on official letter head. In this case only a copy of the report will be released to the requester. Note: Any requests that are extensive may be sent to County Counsel for review prior to releasing records.

   a. A discovery request will be open in LIMS and a copy of the report will be imaged.
   
   b. Staff will review the report, draft complete and admin review the request.
   
   c. The clerical staff will send a copy of the report and the request letter to the requesting agency.
   
   d. The request letter will be uploaded to the case in LIMS as a Case Attachment. If a physical file exists, it will also be filed with the original physical case record.

C. **Subpoena Duces Tecum (SDT) in Criminal Case**

1. The Subpoena Duces Tecum will be handled and fee will be charged, by Records Unit, in compliance the CCCSO policy 1.05.68 on SDT. In criminal cases, the laboratory will not turn over the records to defense even if defense counsel requests them in a Subpoena Duces Tecum. The laboratory may turn over records to the clerk of court when coordinated by the District Attorney's office.

   a. If the laboratory is the participating or investigating agency in the case (if the laboratory has been involved in the analysis of the case) then the defense should get the case related records through the discovery process.
   
   b. If presented with an SDT, forward to the unit supervisor or designee involved, who will then contact the DA's office.

D. **Subpoena Duces Tecum (SDT) in Civil Cases and Court Appearances**

1. Refer to CLER.DAT.12

END OF DOCUMENT
I. Policy: An individual with budget authority, typically the Chief or a Forensic Manager, will review, approve and authorize the purchase of supplies and services.

A. Supplies are ordered on an "as needed" basis.
   1. The Laboratory has two types of supplies.
      a. Office Supplies
      b. Laboratory "Unit" Supplies

B. Office and Unit supplies are placed on the “Order Requests Spreadsheet”.
   1. The following information is entered:
      a. Vendor Name (For Unit Supplies)
      b. Date
      c. Requestor
      d. Item Number
      e. Quantity
      f. Unit
      g. Price per Unit
      h. Item Description

C. Preparing Orders from the "Order Requests Spreadsheet"
   1. The clerical staff will create orders per vendor.
   2. The orders are submitted for approval.
   3. Orders are approved by a Manager or Chief.

D. The Biology Unit (Unit Supplies)
   1. The Biology Unit uses a database of supplies and vendors to generate orders.
      a. The orders are submitted for approval.
      b. Orders are approved by a Manager or the Chief.

E. Placing Orders
   1. Prior to placing an order, verify the vendor information, such as vendor name, purchase order (PO) number, account number, address, telephone number or buyer identification number. If using the general order form, the vendor information is located on the top portion.
   2. When placing an order ensure the transaction details are documented, such as your initials and date, the name of the vendor representative and the order confirmation number. Procurement card orders follow a standardized process and are tracked using appropriate county forms.
   3. The confirmation number is considered the tracking number.

F. Ordering using Procurement Card
1. Order requests including detailed information are submitted to the Chief for review. Email is the preferred method for placing requests using the procurement card process. For tracking purposes, the email should include the requesting staff, supervisor, manager and authorized Forensic Services Division (FSD) Clerk. For ordering purposes, the authorized clerk is individually assigned a county credit card.

2. Upon approval from the Chief, orders may be placed by the authorized FSD clerk using the procurement card process.
   a. A credit card authorization form is generated by the clerk and signed by the Chief.
   b. The clerk places the order and retains the credit card authorization form.
   c. Upon receipt of the items and verification against the packing slip, the clerk reconciles the order against the credit card statement. The clerk is responsible for maintaining a transaction log with copies of all receipts and documentation of purchases each month.
   d. The clerk forwards the purchasing documents to the designated Department's Fiscal Unit account clerk.
   e. The single purchase limit is $2,000.00 and the 30-day purchase limit is $10,000.

G. Purchase Orders with Select Vendors (Supplies & Services)
   1. A Purchase Order (PO) may be generated for vendors that the laboratory uses on a routine bases for supplies or maintenance services or for single purchases. A vendor may request a copy of the PO, which can be accessed on the County Website in the following manner:
      a. Go to the County Intranet website
      b. Under Departments and Offices select Public Works
      c. Click on Purchasing Services
      d. Click on Department Blanket Purchase Order List
      e. Under Department, select Sheriff-Coroner, you may click on include archived list
      f. Select sort list by vendor name or other options - Click View List
      g. Click on the vendor's Purchase Order Number to view and print/export the PO details.

H. Back Orders
   1. When back ordered items are encountered, document the expected delivery date (if known) and notify the requesting unit or person.

I. Receiving Orders
   1. The contents of all orders must be inventoried using the packing slip.
   2. The packing slip must be initialed, dated and indicate the results of the inventory.
   3. If the items received need verification, an individual from the ordering unit must initial and date the packing slip.
   4. If a discrepancy is identified, the Unit Supervisor or Manager must be notified.
   5. If multiple packages of the same item are received, they may be marked for inventory control using the convention: 1 of X, 2 of X, 3 of X and so forth (X being the total number of packages).

J. Record Retention - Orders, Packing Slips/Receipts and Invoices
   1. The Clerical staff maintain a record of the orders placed along with the packing slips/receipts and invoices received. The records are maintained in the Clerical Section vendor binder (current year only) and electronically in the Clerical Unit folder.
   2. To ensure accurate and timely payment, the designated Department's Fiscal Unit account clerk will receive the ordering documents/forms, original packing slips/receipts and invoices. Orders designated to Org 2557 will be noted on the ordering document and invoice.
I. Policy: The Criminalistics Laboratory clerical staff is responsible for the collection and transmittal of payroll forms to the payroll unit.

A. Signatures

1. The Absence Report Forms (ARFs) are typically approved and signed by the supervisor of the unit. Once approved they should be placed in the black payroll bin located in Clerical section. It is the responsibility of clerical staff to place approved absences on the appropriate calendar. ARFs must be signed by the forensic manager or chief prior to transmittal.

2. ARFs pertaining to the Forensic Manager must be submitted to the Chief for approval and signed prior to transmittal.

B. Family Medical Leave (FMLA), Worker's Compensation, or LC233

1. Ensure the indication box is checked on ARFs submitted for medical related absences. Supervisors must initial in the provided space, as indicated on the form. Generally employees will have discussed the circumstances with their supervisor, and if additional paperwork or medical documentation is needed, it can be forwarded to Sheriff's Office Administration.

C. Submitting Payroll Forms

1. Payroll forms are submitted to the payroll clerk on a weekly basis or more frequently, if possible. All payroll forms should be placed in transmittal envelopes.

2. Payroll forms and cards are typically hand delivered, but also may go through county mail.
   
   a. The payroll clerk for the Forensic Services Division is located in the Administration building (651 Pine Street, 6th floor, Martinez).

3. Faxing or emailing the forms may become necessary to expedite timely processing. Payroll closing dates are published and sent to all Office of the Sheriff Department employees, via email.

D. Overtime cards

1. Overtime is usually pre-authorized, and overtime cards are typically approved and signed by the unit supervisor or Forensic Manager.

2. Ensure the overtime card is complete. Check that proper information is recorded, including: name, employee number, hours, dates, signatures, and org number. The overtime card is a two part form, the bottom page is the employee's copy. If not separated by supervisor, the payroll clerk will distribute the employee's copy.

E. Miscellaneous

1. Maintaining a adequate supply of payroll forms is a function of the clerical staff. ARFs and Overtime Cards are stored in the supply carriage. Inform a supervisor and/or clerical staff when the supply is low. Since these are multi-part NCR forms printing via the Contra Costa County Print & Mail Services Department can take several weeks.

2. Single part payroll forms and other payroll related forms are available on the "So_admin" or "So_comm1" server in the "Forms" folder.

3. Any questions regarding forms should be directed to the payroll clerk.

END OF DOCUMENT
I. Policy: Telephone calls to the Criminalistics Laboratory can be for different purposes. Understanding the nature of the call is crucial for proper handling and routing.

A. General Greeting
   1. When answering the telephone you should always state the name of the facility as well as your name.
      a. Good morning Crime Lab, this is ____________
   2. When multiple telephone lines are ringing, place the caller(s) on hold, by letting them know:
      a. Good afternoon Crime Lab, I have a call ahead of yours, can you please hold?
      b. Once you return to the call that was once placed on hold, thank them for being patient and proceed with the call by asking them how you can assist them.

B. Proposition 115 calls
   1. Proposition 115 (Prop 115) enables Criminalists to testify telephonically for Preliminary Hearings. Officers call to speak with the Criminalist, asking a series of questions regarding the analysis. The information on the questionnaire is then used by the testifying officer as "hearsay" to testify on the lab findings.
   2. Prop 115 calls require retrieving the original report from the file cabinet. An Out Card is completed and inserted in place of the original report. The Out Card is completed by indicating the date, lab report number, and initials of the person to whom the report is relinquished.
   3. The analyst is given the original report and notes before speaking with the officer. After the Prop 115 is completed, the analyst places the original report in the refile bin located in the clerical section. The clerical staff will then refile the original report into the filing cabinet and remove the out card.
   4. Occasionally officers will call for Prop 115 testimony while the Criminalist is out of the office. Regardless of the reason for the Criminalist's absence the officer must be accommodated when the Prelim is about to commence. The clerical staff must explain that the Criminalist is unavailable, and instruct the officer to inform the DA. The DA must decide if the officer will do an Official Record with the Supervisor or Manager as Custodian of Records. When available, the supervisor who administratively reviewed the report will do the Official Record.

C. Court Calls
   1. District Attorneys (DAs) call Criminalists prior to trial dates in order to discuss the case with their subpoenaed witness in preparation for trial. The DA will also be calling to initiate the report preparation with the Laboratory clerical staff. The clerical staff will ask the DAs questions to set up the case for court.
   2. Once this information is obtained, the clerical staff pulls the original report and inserts an Out card in its place, then the Criminalist can speak with the DA.
   3. After discussing the case with the DA, the Criminalist will return the case file to the clerical staff for copying and refiling.
   4. Telephone logs are completed by the Criminalist for purposes of recording the pertinent information discussed over the phone. When a telephone log is completed, it is attached to the report as an administrative document. Subsequent related calls will be recorded on a new log. The telephone log should contain the lab number, Criminalist's initials, date of communication and who they communicated with.

D. General Telephone Instructions
   1. District Attorneys and most agencies are able to access lab reports via ARIES. Lab results are never given out over the phone by clerical staff.
   2. Refer calls regarding Drug Alcohol and Toxicology analyses to that section.
3. Calls regarding Coroner's Autopsy Reports are referred to the Coroner's office.
4. The laboratory does not provide information to private citizens/suspects. Refer these requests to the involved agency or District Attorney's Office.

E. Transferring Calls

1. Telephone calls are transferred by depressing the Tran button while caller is on the line. Immediately after, enter 5 and four digit extension of lab location or individual to whom call is being transferred to. For 313 prefix enter 3 and the four digit extension. Complete transfer by hanging up the phone. If the phone call is being transferred to a party outside of the facility you must enter the the full telephone number; and area code if the call is not local, then hang up.

2. Currently, there's a Department telephone roster located

F. Paging

1. Go to Features on the telephone, hit 4 # # 200. You will hear a slight beeping sound. Pick up the telephone receiver and begin to speak. This allows you to page throughout the facility. Paging is only used when necessary, such as crime scenes or emergency instances.

END OF DOCUMENT
I. Policy: The following procedure will be followed for Petty Cash.

A. The Criminalistics laboratory is allotted $150.00 in the petty cash fund. This fund is used by the laboratory staff to make small purchases which cannot exceed $25 including tax. The petty cash is held by the Crime Lab Petty Cash Custodian.

1. For each disbursement made, the staff member must turn in a receipt indicating the amount to be reimbursed. These receipts are photocopied and the original is attached to the Demand and Cash Disbursement Voucher and placed in the petty cash file folder. If a receipt is not available, a receipt must be typed up.

2. The person requesting reimbursement must sign their name, enter their Org#, a description of the item purchased and the purchase amount on the form entitled Demand and Cash Disbursement Voucher. In some instances money can be given when a purchase needs to be made. No more than $25 should be given and a receipt must be obtained and the remaining change should go back into the petty cash fund.

3. The petty cash fund will be replenished when the remaining balance is under $50.00.

B. Steps for the petty cash fund replenishment:

1. Add up the receipt items on the voucher, enter the total, sign and date the Demand and Cash Disbursement Voucher form.

2. The receipts should be in date order and paper clipped to the Demand and Cash Disbursement Voucher.

3. A photocopy of the voucher and receipts will be maintained in chronological order for our records in the petty cash file folder.

4. Staple the original receipts to the original Demand and Disbursement Voucher. (This will go to Fiscal)

5. Contact the petty cash account clerk in the Office of the Sheriff Fiscal Unit to replenish the petty cash fund. The petty cash account clerk check demand and receipts to ensure accuracy.

6. Once the paperwork is checked for accuracy a check will be issued in the name of the Crime Lab Petty Cash Custodian.

C. Currently, checks are cashed at West America Bank. The bank will ask to see identification when the check is endorsed. It is best to ask for small bills and change. The money will be put in the cash box and placed in a secure location. A new voucher should be started.

D. Petty cash should be counted periodically to ensure there is enough money on hand.

E. The auditor's office may periodically audit the petty cash box. If there is an overage, a memo needs to be written to our account clerk advising them of our overage with the amount noted.

1. Ask the account clerk to deposit the overage into the fund The description should read unidentifiable overage.

2. Attached is a copy of a petty cash overage memo.
I. Policy: Opening mail on a daily basis is a function of the laboratory clerical staff.

A. Inter-office mail
   1. Inter-office mail is received from the multiple Departments/Divisions within Contra Costa County and the Office of the Sheriff. These documents are contained in inter-office transmittal envelopes.
   2. Inter-office mail may contain subpoenas, request forms, job announcements, and payroll documents, etc.

B. U.S. Mail
   1. U.S. mail is received from various postal carriers.
   2. U.S. mail may contain checks, bills, discovery requests, and periodicals, etc.
      a. Periodicals are to be date stamped, the table of contexts is photocopied and routed to staff. (See Library procedures)
   3. Payment/checks received are date stamped and delivered to the account clerk at the Forensic Services Division, Fiscal Unit.

C. Proficiencies
   1. When proficiency tests are received, the packaging and paperwork are date stamped.
      a. Start a chain of custody sticker.
      b. Log in the sample to reflect the description contained on the paperwork.
      c. Follow any special instructions regarding storage of evidence, as indicated "to be frozen" or stored in a dry location, etc.
      d. E-mail the Forensic Manager or Supervisor regarding the receipt of proficiency test.

D. Incoming and Outgoing Mail
   1. The mail bins located in the reception area of the laboratory are labelled: Incoming, Outgoing and Outgoing Transmittal. Curriers place the mail in the "Incoming" bin. Laboratory staff place mail in the Outgoing and Outgoing Transmittal bins.
I. Policy: The Criminalistics Section library is a resource available to staff. Staff are encouraged to remain current with forensic publications.

A. Journals and Magazines
   1. When new literature (Journals and Magazines) arrive, they should be date stamped.
      a. The table of contents should be copied and attached to a route slip for pertinent staff members.
      b. Completed route slips will be returned to clerical staff and placed in the "Routed Journal" binder, which is located in the library.
   2. All journals and magazines have a designated section in the library.
      a. Magazines are disposed after a year.

B. Entering Books in the Library Database
   1. When a new book arrives, it should be stamped with the "Contra Costa County Criminalistics Laboratory Library" stamp. All information relating to the book should be entered in the Library Database. The Library database is located on the G drive, in the Lab Folder.
   2. New books should be routed to all staff members or as determined by the Forensic Manager. A route slip should be filled out and attached to the book.
   3. When the route slip has been circulated to pertinent staff, make a copy of the table of contents and file it in the "Routed Book" binder, located in the Library.

II. Assigned Locations
   A. Place the book in its assigned location according to the Library spreadsheet. All literature is divided up by disciplines, i.e Latent, Firearms, Biology, etc.

III. Checking Out Literature from Library
   A. An out-card should be filled out as a place holder when checking out literature from the library. Once the literature is returned the out-card is removed.

IV. Literature Rack
   A. The literature rack is used for the most recent publications. Magazines and journals are placed on the rack for a month, and a copy is distributed via route slip. Magazines and journals are then filed in the Library.

END OF DOCUMENT
I. Policy:  The following procedure will be followed for laboratory laundry.

A. G&K Services is our current service provider for laundering of laboratory coats and towels. Soiled laundry is collected in the hamper located in the Chemical Store Room, and picked up on a weekly basis. A tally sheet is used by staff to account for the laboratory coats and towels deposited into the laundry bag/hamper awaiting pick-up. A tally sheet is started each week after pick-up and maintained with the hamper.

1. Laundry soiled with potential bio-hazards, e.g. blood, will be placed in a red dissolvable bag and secured prior to being placed in the laundry hamper.

   a. Red dissolvable bags will be supplied by G&K.

2. Each laboratory coat or towel deposited into the hamper will be noted on the tally sheet. Ensure that the tally sheet accurately reflects the items being sent for laundering.

3. The G&K representative conducting the weekly pick-up will need a signature (typically on a hand held device) in order to generate a laundry receipt. The soiled laboratory coats being released, as well as, the clean coats being received will be recorded on the G&K laundry spread sheet. The individual making the entry will initial and date the spread sheet.

4. Remove the outgoing laundry bag from the hamper and place a new plastic bag in the hamper. Never touch soiled laundry with bare hands, always wear gloves.

5. Incoming laboratory coats and towels are placed in the wardrobe closet located in the Crime Scene area.

6. If new laboratory coats need to be ordered, notify the G&K representative. Typically three coats are ordered for each staff member. Provide G&K with the style, size and name.

7. If laboratory coats are no longer needed and are being returned, notify the G&K representative to cancel the account for that staff member. For billing purposes, it is important to return all laboratory coats. (However, if a missing coat is later found, notify the G&K representative and the account will receive a credit).

END OF DOCUMENT
### Reference Blood Evidence Kit Assembly

#### A. Materials:

- Generally 100 kits are assembled using the following materials or equivalent:
  1. Whatman FTA mini-cards (100/box): Tritech Forensics # BODPA-FTA-2
  2. White Pillow Boxes (250/pkg): ULINE #S-13402W
  3. Pre-printed RBEK envelopes (500/order): General Services Division (GSD) Print and Mail
  4. Zip-Top plastic bags: 10x12 inch used to contain assembled kits
  5. Labels:
     a. Return address labels: Avery 5267
        i. Print required number of return address labels (template 5167), font; Tahoma, size; 9, with the following information:
           1. Kit Assembly date: X/XX/XXXX and your initials.
           2. FTA Card Lot: xxxxxx. Use the lot # printed on the FTA card and not on the box containing the cards. (Each box of cards is it's own separate lot #).
     b. Small, removable adhesive labels (used to secure RBEK envelope flap)

#### B. Kit Assembly:

1. Wear gloves, lab coat and mask.
2. Clean assembly area with 10% bleach solution and dry.
3. Place clean butcher paper on the work surface.
4. Place a return address-sized label on the back side of each RBEK envelope at the bottom; leave room to add another COC if necessary.
5. Tuck one FTA card into a pillow box and place this assembly inside a RBEK envelope.
6. Place a small removable label across the envelope flap to secure the envelope.
7. Place 25 assembled RBEKs inside a 10x12 inch zip-top bag.
8. Store kit materials and assembled kits indoors at controlled room temperature and humidity.
9. Provide assembled RBEKs to the Coroner's Office, as needed.

**Note:** The pre-printed instructions on the RBEK need to be corrected to reflect the use of pillow boxes instead of pouches with desiccant. A label which captures the correct information must be placed over the pre-printed instructions on the front of the RBEK. See yellow highlighted area in image below. The "Fix-it" labels can be found at G:\Serology\Forms & Logs\RBEK. Continue to correct the RBEK envelopes until the supply of kit envelopes has been consumed.
I. Policy: Non-conforming work includes any aspect of testing or work product that does not conform to laboratory policies, procedures or the agreed requirements of the customer. When non-conforming work is encountered in the Clerical Unit, action is taken to address the non-conformity or quality issue.

A. The appropriate corrective action taken is based on the type of non-conformity, the magnitude/scope of the problem, and whether the non-conformity was isolated or repetitive. When clerical staff become aware of non-conforming work they should notify their Supervisor/Manager. See FSD.15 for more information about the evaluation of non-conforming work.

1. Corrective Action (Most Significant): Action taken to address a significant technical or quality issue. The non-conformity requires documentation of the corrective action per Division policy and procedure. See FSD.15 for more information.

2. Level 2 Non-Conformity: These incidents do not cause immediate concern for the quality system but may have an isolated effect, tend to be individual events, and are addressed on a case-by-case basis. These non-conformities have the potential to be re-mediated.

   a. Level 2 non-conformities may include but are not limited to:
      i. Not following current published Clerical or Division policies and procedures.
      ii. Repeated Level 1 errors.
      iii. Transcriptional or spelling corrections made by clerical unit that require an amendment after the release of a report.

   b. Documentation of a Level 2 non-conformity will be maintained within the unit and will be evaluated by the Supervisor/Manager. The documentation should include, as applicable:
      i. Describe the quality issue. What is the problem (error or non-conformity)?
      ii. An explanation of how the quality issue occurred. Why did it happen?
      iii. An explanation of the action taken to correct or improve the quality issue. What was done to correct the problem?
      iv. An evaluation of the impact (if any) on casework, equipment, etc. How significant is the problem?
      v. Notes for any monitoring or follow-up. Was the correction effective?

3. Level 1 (Least Significant): These incidents are unlikely to reoccur, are not systemic, and do not affect the fundamental reliability of the work product.

   a. Level 1 non-conformities may include, but are not limited to:
      i. Grammatical or Typographical Errors: spelling/grammar mistake in report or notes, or wrong agency case number or requestor in LIMS.
      ii. Correction of Chain of Custody: Location or date corrections are caught prior to release of the report.
      iii. Missing initials/date on evidence.

   b. When brought to the clerk’s attention, this type of non-conformity is typically corrected immediately by the clerk. A record of the correction may be captured by the clerk’s initials/date as outlined in Division Policy FSD.42 and FSD.43.
Contra Costa County
Office of the Sheriff

<tr>
<td>Returning Evidence</td>
<td>Returning Evidence and Evidence Transfers</td>
</tr>
</tbody>
</table>
I. Policy: The following procedures will be followed for subpoena acceptance and distribution.

A. General

1. Subpoenas are generally sent to the Drug, Alcohol and Toxicology Lab via fax or email. The subpoenas are received into the MuirLab e-mail in box or paper copies are placed in the incoming subpoena tray.

2. Prior to subpoena service or rejection, consult the Muircalendar for staff availability.

3. Associated lab report numbers are required for all personally served subpoenas. If not indicated on subpoena, lab report numbers can be researched in LIMS by cross-referencing the agency with case file number, or defendant name. If information does not match, the subpoena must be rejected.

   a. Paper subpoenas will be scanned into a .pdf format, so they can be electronically stamped and returned.

   b. The subpoena is then opened in Adobe and an information "stamp" is added electronically. This will allow for the addition of pertinent information to the pdf which is sent back to the DA's office. An electronic copy of the rejected subpoena will be kept on the shared drive, until after the trial date on the subpoena.

      i. To set up Adobe Pro for use of electronic "stamps"

         1. Run Adobe Pro
         2. Click the Comments toolbar.
         3. Click on the stamp icon with the pull-down menu triangle next to it.
         4. Select the stamp you want to use from the previews.
         5. Click on the document where you want the stamp to appear.

      ii. To set up Adobe Pro as the default:

         1. Right click on any document and choose "Open with"
         2. Click "Choose Default Program" from list
         3. Click on "Adobe Acrobat Pro"
         4. Check box "Always use this selected program to open this kind of file"

      iii. To use the electronic "stamp":

         1. Open the document you want to stamp in Adobe Acrobat Pro (do not use Reader).
         2. Click the Comments toolbar.
         3. Click on the stamp icon with the pull-down menu triangle next to it.
         4. Select the stamp you want to use from the previews.
         5. Click on the document where you want the stamp to appear.
6. If there are any form fields in the stamp to fill in, Adobe will prompt you for those values.

B. Preliminary Hearing

1. For electronic subpoenas, a copy may be emailed directly to the criminalist at or near the time of receipt. The date and time of the email that is forwarded will be considered the service date. **A proof of service is not required by our DA's office.**

2. If criminalist is unavailable, electronically stamp "**BUSINESS RECORDS**" and return the subpoena to DA's Office. The subpoena is not signed or date stamped. For reference purposes, a copy of these rejected subpoenas are retained electronically saved on the shared drive until after the hearing date on the subpoena. Electronic images of the served subpoenas are made available to the criminalists.

3. An **Official Record** testimony can be provided by the Supervisor, Manager or designee as Custodian of Records.

4. Alternately, the Business Records testimony is done by a qualified criminalist.

C. Trial

1. If criminalist is available, serve subpoena as noted above.

2. If criminalist is unavailable, an electronic stamp may be added to the pdf through Adobe. Indicate dates criminalist will be unavailable and reason (i.e. training or pre-approved time off). Return the electronic version of the subpoena to DA's Office, retaining a copy on the shared drive until after the trial date on the subpoena.

3. To Serve a Declaration in Outlook
   a. Navigate to MuirLab Inbox
   b. Open Subpoena Email
   c. Open attachment in Adobe Pro
      i. Click "Comment"
      ii. Click "Stamp Picture"
      iii. Click "CCC Subpoena Return Stamp Extended"
      iv. Click Cancel for the Identity Set Up
      v. Place the stamp on the pdf and click for placement of electronic stamp
         1. The following will pop up
            1. Begin Date
            2. End Date
            3. Analyst's Name

4. Saving electronic declarations or rejections:
   a. Save on L/Lab/Muir/Declaration
      i. Choose appropriate analyst name
      ii. Change file name to: Suspect's last name, Year, Month, Day
5. Faxing electronic declarations or rejections:
   a. Choose File
   b. Click Print
      i. Choose Printer "Fax Via Copier"
   c. Click Print
      i. Type Recipient's Name (Located on subpoena)
      ii. Fax Number (Located on subpoena)
      iii. Click "OK" to send

D. Juvenile
   1. Subpoenas for Juvenile hearings are served as noted above for trials.

E. Public Defender/Private Attorney
   1. Public defender/private attorney subpoenas are expedited. Determine if the criminalist has already been
      subpoenaed for the case by the District Attorney. If so, inform criminalist. Subpoena will automatically be
      served.
   2. Frequently, public defender/private attorney subpoenas do not indicate the associated lab report number. This
      must be determined before serving the subpoena. This information is obtained by calling the public defender
      subpoenaing the criminalist.
   3. The individual serving the subpoena must sign and date the Proof of Service, and send the Proof of Service back
      to the public defender's or private attorney's office.
   4. The subpoena, along with a copy of the associated lab report, is delivered to the criminalist by placing it in their
      In Box as soon as possible.
   5. If the subpoena is rejected or requires a declaration, it will be scanned into a pdf and kept electronically on the
      shared drive.

F. Grand Jury Subpoenas
   1. These subpoenas are also expedited. If the criminalist is available and the associated lab report numbers are
      provided, the subpoena can be served. The individual serving must date and sign the Proof of Service, and return
      the Proof of Service via inter-office mail or via FAX to the appropriate DA.
   2. A copy of the subpoena and proof of service, along with a copy of the associated lab report, is delivered to the
      criminalist by placing in their In Box as soon as possible.
   3. If the subpoena is rejected or requires a declaration, it will be scanned into a pdf and kept electronically on the
      shared drive.

G. Breath /Draeger Subpoenas
   1. These terms are interchangeable. In lieu of submitting a blood sample, the suspect in these cases has provided a
      breath sample by blowing into a Draeger Alcotest instrument to determine the Breath Alcohol Concentration.
   2. Testimony for jury trials on these cases is done on a rotational basis, in date order. The breath case rotation
      chart is kept on the attendance board in the clerical area. The criminalist who is next up to testify will be the
      criminalist with the oldest date.
   3. As these subpoenas are not for a particular criminalist, and the lab is always able to provide an expert for
      testimony, these subpoenas may not be retained on file.

H. Subpoenas for Former Employees
   1. The laboratory is not responsible for the court appearance of former employees. If the laboratory has the contact
      information, it is provided to the attorney sending the subpoena.
   2. The laboratory maintains contact information for former employees only if they are currently employed by other
      government/law enforcement agency or have signed a contract with the DA's office to testify on their own
      casework upon retirement. This information is on file in the subpoena drawer.
      a. Should the subpoena be for a former employee who does not meet the above requirements, the subpoena
         is returned to the DA. A declaration is included stating that the employee no longer works for the Crime
         Lab. The DA's office may consult with the laboratory Supervisor/Manager to discuss the course of action
         to be taken in such cases.
I. Miscellaneous:

1. Should a criminalist be summoned for **jury duty**, the subpoena is returned to the DA with a declaration indicating this. Subpoenas are rejected only for the obligatory date or dates indicated on the jury summons. The criminalist informs the lab of the status of this obligation.

2. Prior to requesting **vacation time** off, a criminalist will check his/her subpoenas that have already accepted. If there are accepted subpoenas for the requested vacation dates, it is the criminalist's responsibility to clear these subpoenas with the DA.

3. Should a criminalist be scheduled for **training** after subpoenas have been accepted for the training dates, the subpoena clerk will return the subpoenas to the DA, including a declaration to this effect. Criminalists will be responsible to check all accepted subpoenas for that date range and send them back to the clerks to issue declarations.

4. Electronic subpoenas will be delivered via e-mail to analysts as soon as they are accepted. Paper subpoenas may be delivered to criminalists via their in-box.

END OF DOCUMENT
I. Policy: Telephone calls to the Muir Lab can be many and quite varied. Understanding the nature of the call is crucial to proper handling and routing. The following represents some of the more common types of phone calls received at the Drug, Alcohol and Toxicology Lab.

A. Proposition 115 calls

1. Proposition 115 (Prop 115) enables Criminalists to testify telephonically for Preliminary Hearings. Officers call to speak with the Criminalist, asking a series of questions regarding the analysis. The information on the questionnaire is then used by the testifying officer as "hearsay" to testify on the lab findings.

2. Prop 115 calls require retrieving the original report, notes and other related documentation.
   a. For physical copies, retrieve them from the file cabinet. An Out card is completed and inserted in place of the original report. The Out card is completed by indicating the date, lab report number, and initials of the person to whom the report is relinquished.
   b. For electronic copies, retrieve them from LIMS. The report can be printed or viewed by selecting "Print Final Report" from the request menu. The notes can be printed or viewed in the attachments tab as a .pdf request image. The image will be labeled "Worksheet" with the lab number after it. Other documentation will be included in the case images (also under the attachments tab) or mentioned in the "Case Info" report (under the case info tab). See CLER.DAT.16.

3. The analyst is paged and summoned to the front office, in order to reference the original report and notes while speaking with the officer. The analyst places the original report in the filing tray when Prop 115 questionnaire is completed. The clerical staff returns the original report to the filing cabinet and removes the out card.

4. If the analyst is located at the Summit Lab when the request for the Prop 115 is requested then:
   a. Obtain a name and telephone number of the caller, and tell them that someone will call them back for the Prop 115.
   b. Immediately call the analyst and let them know that they have a Prop 115.
   c. Scan the report and email it to the analyst with the caller contact information.
   d. If the person at Summit is unavailable, then a qualified analyst will do an Official Record.
      i. The original caller should be contacted to let them know an Official Record will be needed.

5. Occasionally officers will call for Prop 115 testimony while the Criminalist is out of the office. Regardless of the reason for the Criminalist's absence, the officer must be accommodated when the Prelim is about to commence. The clerical staff must explain the reason for the Criminalist's absence, and instruct the officer to inform the DA. The DA must decide if the officer will do an Official Record with the Supervisor or Manager as Custodian of Records. If so, the DA provides the officer with a different, longer questionnaire. Typically the supervisor who administratively reviewed the report will do the Official Record, however any qualified Criminalist may also do an Official Record if the supervisor is unavailable. Alternately, the DA and the defense could stipulate to the analysis. In such a case, testimony from lab staff would not be needed.

B. Court Calls

1. District Attorneys call Criminalists prior to trial dates, in order to discuss the case with their subpoenaed witness in preparation for trial. The DA will also be calling to initiate the report preparation with the Drug, Alcohol and Toxicology Lab clerical staff. The clerical staff asks the DA a series of questions from the Court Questions interview sheet. The questions include information the analyst will need to know when speaking with the DA. See attached example of Court Questions form.
2. Once this information is obtained, the Criminalist can be summoned to the front office to speak with the DA. The clerical staff pulls the original report, notes and other documentation. The Court Questions form is clipped to the report and the packet is given to the Criminalist.
   a. If they exist as physical copies, complete an Out card and insert it in place.
   b. If they exist as electronic copies, retrieve them from LIMS. The report can be printed by selecting "Print Final Report" from the request menu. The notes can be printed from the attachments tab as a .pdf request image. The image will be labeled "Worksheet" with the lab number after it. Other documentation will be included in the case images (also under the attachments tab) or mentioned in the "Case Info" report (under the case info tab). See CLER.DAT.16.

3. After discussing the case with the DA, the Criminalist will return the packet to the clerical staff to complete the report preparation for court. For physical copies, report preparation includes photocopying the original report before filing it away. The report copy or electronic printout from LIMS is stamped with the Copy stamp. Telephone logs are completed by the Criminalist for purposes of recording the pertinent information discussed over the phone. If a telephone log was completed, clip the original log to the report. Subsequent related calls will be recorded on a log. The telephone log should have the Lab number, Criminalist's initials and date of communication.
   a. For physical copies, this original log will be filed at the end of the original report as an administrative document.
   b. For electronic copies, the log will be scanned as a case image (i.e. ADM-01). A "Log--Communication" case activity can be created to direct attention to the scanned case image. See CLER.DAT.16.

4. Finally, chain of custody for the related evidence on the case is printed and attached to the copy of the report and notes. The packet is then placed in the rack at the front desk. The rack is a queue for pending court cases and phone calls regarding particular cases. Prior to leaving for court, the Criminalist will retrieve the packet from the rack.

5. District Attorneys also call to initiate report preparation and speak with a witness on Breath Alcohol cases. These are cases where the suspect has given a breath sample by blowing into the Draeger Alcotest instrument to determine Breath Alcohol Concentration.
   a. The clerical staff obtains the required information from the DA by referring to, and completing the Court Questions form. The completed form is given to an Alcohol unit staff member to print the breath report. When discussing the case with the DA, the Criminalist refers to this report. The Criminalist will take the breath report to court.
   b. After the breath report is printed the Criminalist will need to speak with the DA regarding the case, so the clerical staff must arrange either for the DA to call back to speak with a Criminalist at a specific time, or determine the DA's availability for the Criminalist to return the call. As with a lab report, the DA must discuss the breath report with the designated witness.
   c. Jury trial testimony for breath cases is done on a rotational basis, in date order. Refer to the Breath Alcohol rotation list posted on the attendance board. Inform the particular Criminalist up next on the rotation, there is a pending case. Relay all DA telephone instructions to the Criminalist.

6. In order to minimize time spent in a witness room waiting to testify, the Criminalist, as an expert, is one of the last people to testify at a jury trial. Therefore, it is always requested that the DA call back after the jury is picked and all other witnesses have testified, or about an hour before the Criminalist is needed to testify. This enables the Criminalist to plan accordingly, completing any open casework, and allowing for sufficient travel time to court.

C. General Telephone Instructions

1. District Attorneys and most agencies are able to access lab reports via AIRES. The results are available on ARIES 24 hours after the report has been administratively reviewed. Should an officer, DA, Public Defender, or even a Judge call requesting a lab report, the report is faxed to the requesting person. Since it is usually not possible to verify the identity of the caller, lab results are never given out over the phone.

2. Occasionally relatives of decedents will call to discuss lab results on Coroner cases. These calls are always referred to the Coroner's office. The pathologist is responsible for determining cause of death and communicating this information to family members.

3. Private citizens/suspects requesting lab results are referred to the arresting agency's records unit for this information. Should the case be Contra Costa Sheriff's Office or contract city case, the caller can be referred to CCSO Records. Alternatively, the individual can be referred to either the District Attorney's office or the Public Defender's office should a private attorney not be retained. The lab does not provide this information.
4. **District attorneys** often call to discuss cases with Criminalists. Most of the calls are related to a specific lab report and analyst. In the event the DA does not have a lab report, ask for the suspect's name. Run a name search in LIMS to be sure there is no associated lab report with a specific Criminalist to whom the call should be directed.

D. **Transferring Calls**

1. Telephone calls are transferred by depressing the **Trns** button while caller is on the line. Immediately after, enter the four digit extension of lab location or individual to whom call is being transferred. If the county number is outside the building, then dial 8- (last number of the prefix)- and four digit extension. (i.e. 8-5-1600). Complete transfer by hanging up phone. Currently, G:\Dept Phone List is the location where the most recent phone lists are stored.

E. **Paging**

1. Picking up the telephone receiver and depressing the star (*) button initiates the page. For telephone paging purposes, the lab is divided into sections.

2. Dial 31 for paging into the drug section, 32 for the alcohol section, 33 for the east or Sheriff's Aide area of Toxicology lab, and 34 for the west or Criminalist area of Toxicology lab.

3. Once the beep is heard, speak into the phone, calling the name of the person to be paged.

4. Relay the message in a normal, speaking voice. After the person responds, disconnect by hanging up the phone.

END OF DOCUMENT
I. Policy: The following are instructions for the Access Supply Order Database

A. Introduction This database was created to speed up the regular laboratory consumable supply ordering process in the Drug Alcohol and Toxicology Section. It will help automate and track purchases.

B. Starting Out
When the ordering database starts up, the main switchboard will be visible (Fig. 1). This main menu will allow you to access the regular functions of the database. As it becomes necessary, additional functions can be added to the system.

C. Choose a Location
The database tracks where each order originated. This will help the Account Clerk with billing. The queries in the database will filter out any orders that do not originate with your lab. Because all the subsequent screens are based on the location, it is best to choose the lab location as soon as the database starts up. Most buttons will not open up the subsequent screen if the location has not been filled in.

Enter the location information by choosing the lab name from the "ENTER LOCATION" combo-box located just beneath the EXIT button.

If orders are not appearing in subsequent queries, it could be because the location entered for that order is incorrect.

D. Choose Your Initials
Similarly, the database tracks whoever entered or ordered each item. If there are any questions about the transaction, then that person can be asked about it later.

Enter your initials by choosing them from the "ENTER OPERATOR INITIALS" combo-box located just beneath the EXIT button.

E. Description of Main Menu
The main menu is divided into two columns: forms and reports.

Forms will help with the entry of order information. The forms create, edit, and update orders. The forms will only allow certain information to be edited so that orders will not be accidentally changed or deleted. Use care when entering data-it is harder to fix an error after the form is closed.
The reports will create order invoices to print. There is also a button to take you to less frequently used reports on the Manager's Reports Screen.

There are two items below the green dotted line. These two items are for inspecting the order information if something has gone wrong. These forms do not have write protections on the data, so be careful when changing data on these screens.

The exit button at the top of the screen closes the database and Access.

F. **Starting an Order**
   Push the button labeled "CREATE A NEW ORDER" (it has a graphic of a pencil drawing). This button will bring up a new order entry form (Fig. 2).

![Fig. 2: New Order Form](image)

There are two buttons on the lower left-hand side of the screen marked "CHOOSE ITEM" and "CREATE NEW ITEM".

G. **Choose an Item**
   Use the "CHOOSE ITEM" button to order an item that is already in the database. This will bring up a form to choose an existing item from the database list (Fig. 3).

![Fig. 3: Choose Items Form](image)

The Choose Items Form is only for reviewing and choosing an item already in the database. Therefore, none of the information on this form can be changed.

Items can be sorted "BY NAME" or "BY CATALOG" number. By default, the items are listed "BY NAME" in alphabetical order. Choose an item by clicking the "BY ITEM NAME" pick-list and clicking on the correct item, or by typing in the first couple of letters. When the correct item name is displayed on the pick-list press ENTER on the keyboard. The catalog and vendor information will be displayed in the blanks to the right.

An item can also be browsed by catalog number. Click the "BY CATALOG" button. Choose a number from the "BY CATALOG #" pick-list, and then press ENTER. The full item information will be displayed to the right.

If you cannot find the right item, click the "CANCEL" button. This will return you to the previous screen. You may have to create a new item.

If the correct item information is displayed to the right, click the "CHOOSE ITEM" button. This will fill in the correct information on the previous screen.

H. **Create an Item**
   If an item has never been ordered using the database, it will have to be entered. On the order entry form, click the "CREATE NEW ITEM" button. This will bring up a screen that will allow you to enter all the item information for a new product (Fig. 4).
The "ICODE" blank is greyed-out. This number is automatically assigned by the database and cannot be changed. Fill in the rest of the item information. The "CHEMICAL" checkbox is to show that the ordered item is a chemical. This is used to track items in the SDS part of the database. Be sure to fill in the "LAB LOCATION" blank so the list of items will be filtered correctly on future orders. When all the blanks are filled, click the "CHOOSE VENDOR" button. This will bring up a form (Fig. 5) that will allow you to choose the vendor by an alphabetical pick-list of the vendor code (an abbreviated form of the vendor name).

Select the vendor code from the pick-list, or type the first few letters into the pick-list. Press ENTER on the keyboard when the correct vendor name is selected. The full vendor information will be displayed to the right.

If the displayed vendor information is correct, click the "CHOOSE VENDOR" button. The vendor code will be copied onto the order entry form.

You may click the "CANCEL" button at any time to return to the previous order entry form.

I. **Org Number**

When a valid item has been selected, enter the rest of the information on the Order Entry Form. The Org Number can be filled in by pressing the "CHOOSE ORG NUMBER" button. This will bring up the Org Number Form (Fig. 6).

Percentages and valid Org numbers can be selected from the pick-lists at the top:

1. Fill in the percentage of the first Org number.
2. Left-click on the first pick-list or press TAB on the keyboard to move the cursor there.
3. Generally, 100% is used.
4. Select the correct Org Number from the pull-down menu, if applicable.
5. If necessary, tab over to the second and third percentage blanks and pick-lists to split the order amongst several Org Numbers.

Alternatively, frequently used splits of Org Number can be selected from the shortcut buttons on the lower half of the form.

The form will automatically paste the numbers into the blank below. When the correct Org Numbers are filled in click on the "DONE" button. This will fill the Org Number into the Order Entry Form.

You may click the "CANCEL" button to return to the Order Entry Form without changing the Org Number.

J. **Completing the Order**

All the white blanks should be filled in (Number, Price, Group, Subaccount, Org Number, and comment). The
greyed-out date boxes are for reference only and cannot be changed in this screen.

Double-check the information on the screen. If everything is correct click the "DONE" button. The order information will automatically be saved. If there are any problems, edit the information prior to clicking the "DONE" button. It is much easier to change the order information on this form than it is to edit the information in other parts of the database.

You may click the "CANCEL" button to return to the main menu without saving the order information. Creating a Similar Order

K. Creating a Similar Order

![Similar Order Form](image)

FIG. 7: SIMILAR ORDER FORM

Some items are ordered in similar quantities, or in regular intervals. To create a new order that is similar to one already in the database, click the button labeled: "CREATE A NEW ORDER THAT IS SIMILAR TO A PREVIOUS ONE" (it has a picture of repeating screens).

This button will bring up a form with previously ordered items (Fig. 7). The most recent orders are listed first. The orders can be filtered by vendor code. To do this, select a vendor code from the pick-list in the upper left-hand corner of the screen. Then click the "FILTER ON" button. This will display only the order records from the vendor selected in the pick-list.

Click the "FILTER OFF" button to see all the records from all vendors.

Use the scrollbar to the right of the screen to view the recent orders. When you see a similar order click the "DITTO" button. This will copy the old order information to a new record and allow you to make changes (see "Starting an Order", above).

L. Printing an Order

After the order information is entered, an invoice must be generated and signed by a Manager or the Chief (Debbie McKillop, Danielle Roberts or Pam Hofssass). From the main menu, click on either the "PRINT OUT ALL NEW ORDERS" button or the "PRINT OUT NEW ORDERS FROM A SPECIFIC VENDOR" button. Both of these buttons will bring up a form with two calendars (Fig. 8). Select the starting date by clicking on the top calendar. Select the ending date by clicking on the bottom calendar. Both dates will be displayed in the middle of the form in the blanks labeled "FROM" and "TO".

If you selected the "PRINT OUT NEW ORDERS FROM A SPECIFIC VENDOR" button, then select a vendor code from the pick-list just above the date ranges.

When the correct date range (and vendor) are displayed click the "GENERATE REPORT" button (or click the "CANCEL" button to return to the main menu). This will show the report in the print preview format. If the preview looks correct, then press the button that looks like a printer located just below the Edit menu (Fig. 9). If there is a problem, click the "CLOSE" button located on the same toolbar.
If there are no orders for the indicated date range (and vendor), a message box will appear stating that there is no information to print. You will be returned to the main menu.

**M. Updating an Order**

After an order is signed, the database should be kept up-to-date with current information. Use the "UPDATE ORDER INFORMATION" button from the main menu to enter this information.

The Update Orders Form will open showing the most recent orders first (Fig. 10). The orders can be filtered by vendor code (see "Creating a Similar Order", above).

![FIG. 10: UPDATE ORDERS FORM](image)

If the order information was entered incorrectly, the following information can be changed on this form:

- To change the item that is ordered, click the "CHOOSE ITEM" button just below the yellow item name blank.
- To change the Org Number, click the "EDIT ORG" button just below the Org Number blank.
- "GROUP", "SUB ACCOUNT", and "LOCATION" can all be changed by choosing the proper response from their respective pick-lists.

When an item is ordered by telephone, the "PRICE", date "ORDERED", "SPOKE TO", and "REFERENCE NUM" number blanks should be updated. Click the "TODAY" button just below the date "ORDERED" blank to fill in the current date. If a date is already filled in, the button will not erase the previous data. The old date must be erased first, or changed manually.

**N. Receiving an Order**

When the item is actually received by the lab, more information should be updated. The Verified and Received Dates BOTH need to be updated. To receive the same number of items as were ordered click the "SAME" button just below the "RECEIVED" blank. If the received and ordered amounts differ, fill in the correct amount manually in the "RECEIVED" blank, and enter the reason into the "COMMENT" blank. If the item is a chemical, fill in the "LOTNUM" blank with the lot or batch number. This will aide in chemical inventory and SDS logs later.

When the order information is updated to your satisfaction, push the "DONE" button to return to the main menu.

NOTE: If you use the record navigation buttons at the very bottom of the screen, be aware of where the cursor is located. The record at the top of the screen is not necessarily the record being edited.

**O. Exiting the Database**

Click the "EXIT THE ORDERS DATABASE" button at the top of the main menu. This will close the database and exit out of Access.

**P. Editing Item and Vendor Information**

The two buttons at the bottom of the main menu are for changing mistakes in the database. Clicking on them will bring up forms similar to the "Choose Vendor" Form or the "Choose Item" Form (see above). Unlike the previously mentioned forms, all the fields can be changed. Do NOT use the edit features unless the database has errors. Use the "BACK" button to return to the main menu if you accidentally accessed these forms.

**Q. Manager's Reports Menu**

This button will open up a second menu of less frequently used reports and manager's information screens (Fig. 11).
R. Current Purchase Orders
The button labeled "PRINT OUT CURRENT PURCHASE ORDERS" will open a screen to choose the lab location. Only a single location can be checked. If none of the locations is checked, then the report will print out all vendors that have not been assigned a location. When the "GENERATE" button is pressed, a preview of the current PO list for the checked location will be shown on the screen. If you want to print out the list, click the print button (the same as in the print order form: Fig. 9). Click the "CLOSE" button to return to the main menu.

S. Financial Report
The "PRINT OUT ORG FINANCIAL REPORT" button will open up a new screen to select the date range. It is similar to the one used to select the date of the order form (Fig. 8). When a date range has been selected, press the "GENERATE REPORT" button. A report summarizing the estimated spending for each org is shown. The report is also broken down by each sub-account within the org.

T. No Action Report
The "NO ACTION REPORT" button will preview a report of all the items that have been entered into the database (older than 30 days) that have not been received. This report is useful for finding items that have been "forgotten" on back order, or that arrived, but were never updated properly.

U. SDS Location Entry Form
This button opens up a screen to list all the areas that a certain chemical item is used. There is a single set of location information for each item in the database (although, if multiple items exist like different sizes, or vendors, then location information will have to be filled out for each one). Blanks are also provided for entering comments or CAS numbers. SDS Location Report This button opens up a form to choose a location. When a location is checked, and the "GENERATE" button is pushed, a report is created listing all of the chemicals used at that particular location.

V. Creating Backup Databases
Before entering the monthly order into the database, create a backup of the most recently used database and save it to the "BACKUPS" folder. This will ensure that a correct and functional copy of the database is always available. To create a copy, right click the "SUPPLYOR" icon in the MUIR ORDERING DATABASES folder and select COPY. Open the BACKUPS folder and select PASTE. Rename the backup database "BACKUP 'DATE' SUPPLYOR". For example, a backup created on January 1, 2000 would be named "Backup 1-1-2000 Supplyor". Keep back up copies saved in the Backup folder for 3-6 months before discarding.

W. Troubleshooting
Note: The following procedures are briefly explained in order to fix commonly occurring database errors. The procedure for fixing these errors, however, involves opening up database tables, or editing unprotected forms. Do not attempt the changes unless you are familiar with Access and have a handy backup of the database.

Q. An order that was just entered does not appear in subsequent screens.
A. The order editing screens filter out any orders that are not from the current location marked on the main menu screen. Manually check the location of the order using the ORDERS TABLE in the database

Q. I cannot find the ORDERS TABLE listed above.
A. The database window is hidden to prevent accidental changes. Pull down the WINDOW menu. Click UNHIDE. Select "SUPPLY ORDERS: DATABASE"

Q. New orders will not print out.
A. First, check the location as above. Also, the report will only print out orders that have an "ENTERED" date, but not an "ORDERED" or "RECEIVED" date. Delete the "ORDERED" or "RECEIVED" dates out of the ORDERS TABLE in the database and try to print again.

Q. An item (or vendor) in the database keeps appearing with the wrong information (price, packaging, etc.).
A. Edit the items by using the button marked "EDIT ITEM INFORMATION" (or "EDIT VENDOR INFORMATION").
NOTE: Items should only be edited if the original information was entered incorrectly. If the item information was valid, but has changed (i.e. at one time the item came in packs of 3, but now the company sells only packs of 6), a copy of the old information should be left in the database. Create a new item record with the updated information, and mark the old record as outdated. If the outdated checkmark is set to true, it will remain in the database so that the old orders will print correctly, however, it will not appear in queries for selecting items for new orders.

Q. An item on the printed order report does not show a sub account number or shows the wrong one.
A. Edit the order by pressing the button marked "UPDATE ORDER INFORMATION" on the main menu screen. Change the "SUBACCT" blank to reflect the correct information.

END OF DOCUMENT
I. Policy: The following are instructions for the Intoximeters Operator Entry Database.

A. The Intoximeters online database contains the dates of training sessions, names of instructors, and names of trained officers.
   1. The database is located at http://soweb/Muirlab

B. Instructions for entering trained operators:
   1. Sign into the database. Click the "Intoximeters" button.
   2. Select the Operator tab from the menu located at the top of the screen.
   3. Click "Add new operator" and a new window will pop up. Enter the operator's name and badge number, and select the agency from the drop down list.
   4. Select "Yes" from the "Active" drop down list.
   5. Check the box for "Include Training".
   6. Input the training date, and select the instructor from the drop down list.
   7. Select "Pass" from the "Status" drop down list.
   8. Click the "Submit" button to save.

C. Instructions for printing a single operator card:
   1. Search for an existing operator by using the search box under the Operator tab.
      a. To search for an existing operator, the operator's first and last name are necessary. The operator's badge number and agency are helpful in order to distinguish between multiple operators with the same name.
   2. Enter the operator's first name, last name, or both first and last name. Click the magnifying glass button, or press the enter key on the keyboard.
      a. A partial first or last name search can be used if the complete name is not known.
      i. For example: "Udow" will yield the result "Udowski John".
      b. If entering both the first and last names, they must be entered with the last name typed in first, with no comma between the names. Any other format will yield no results.
      i. For example: "Udowski John" not "Udowski, John" or "John Udowski"
      ii. Searching by the operator's badge number or agency will yield no results.
      iii. If the search yields multiple results, compare the operator's agency and badge number to the results to locate the correct operator.
   3. Once the operator's entry has been located, click on the "history" link at the far right of the entry.
4. Under "operator reports" select "card label" from the drop down list, and click the "display" button.

5. Click the "print file" button. Print the card onto ID badge stock #43879.

6. To print the accompanying agency letter, select "agency letter" from the "Operator Reports" drop down list. Click "display" then the "print file button", and print onto letterhead. Agency letters must be signed by the Forensic Manager.

7. To print the accompanying agency address label, select "mailing label" from the "Operator Reports" drop down list. Click "display" then the "print file" button, and print onto standard address labels (For example Avery 5960).

D. Instructions for printing operator cards for an entire class:

1. Under the Operator tab, click the "reports" link.

2. Select the training date from the drop down list.

3. Select "card labels" from the report drop down list and click the "display" button.

4. Click the "print file" button and print cards (ID badge stock # 43879).

5. To print the accompanying agency letters, agency address labels, or class roster, leave the same training date selected in the drop down list.

   a. Choose the report from the "Select Report" drop down list, click "display" then the "print file" button.

   i. Mailing labels should be printed onto standard address labels, such as Avery 5960.

   ii. Agency letters must be printed onto Sheriff's Department letterhead and signed by the Forensic Manager.

E. Instructions for laminating operator cards:

1. Operator cards should be inserted into credit card sized laminator pouch with a thickness of 7 millimeters, then placed inside a carrier sleeve before sending through the laminator.

2. The small laminator is permanently set to the correct temperature, and can laminate one card at a time using a small carrier sleeve.

3. The large laminator needs to be set to a temperature of 130 C, and can laminate up to eight cards at a time using a large carrier sleeve.
I. Policy: The laboratory complies with all legitimate Discovery and Subpoena Duces Tecum requests. These requests typically pertain to documents related to the analysis of samples or records kept in the normal course of Laboratory business. Please see the Division Manual (FSD.45) for more information on handling discoveries and Subpoena Duces Tecum.

A. Basic and Extensive Discoveries: All criminal discoveries are routed to the Forensic Services Division via the District Attorney's Office. The discoveries for the DMV hearings, Civil SDT's, DMV Admin per se SDTs or other official government agency requests (Such as State Licensing Bodies) are not routed via the DA's office.

1. A basic discovery is a pre-set discovery packet. A basic blood discovery is typically comprised of a copy of the report and notes, a copy of the chain of custody for the evidence, instrument maintenance and calibration logs. A basic breath discovery consists of the breath test card, instrument calibration and maintenance records and the operator's certification.

2. An extensive discovery is not a pre-set package. It may be a request for more detailed documentation than the basic discovery packages. See the Blood and Breath Alcohol Technical Unit Manuals for more information about a basic and extensive discovery for alcohol analysis.

3. The requesting party or the suspect's defense counsel, may send a written request to the District Attorney's office.
   a. The DA's office will review all discovery requests for relevance.
   b. The DA's office will then FAX an Investigations Request Form to the Drug, Alcohol and Toxicology Section with the request.

4. If the discovery is requested by a Public Defender, forward the request to the DA's office and advise the Public Defender to submit the request via the DA's office.

5. Basic discoveries are also requested and completed for the District Attorney's office.

6. Discovery requests are typically received as a FAX, email, or by US mail. The original report, along with request letter are scanned into LIMS and a discovery request is opened and logged in LIMS.

7. The paperwork is delivered to the Staff member or the Technical Unit that needs to complete the discovery. An analyst will compile the records and add them as images into LIMS. Analysts will draft complete and admin review the requests.

8. The discoveries are routinely logged in and processed in date order.

9. Lab staff will upload the records into LIMS, draft-complete, and admin review the discovery request. Images in the discovery request that have been marked "Send To iResults" will appear on ARIES where the District Attorney can retrieve them.

10. Most discovery requests will be made available electronically through ARIES for the District Attorney to retrieve the records. ARIES has a 24 hour delay, after the request is Administrative Reviewed in LIMS, before the records will be accessible to be retrieved by the District Attorneys.

11. Alternately, if the documents are needed as a "Rush", or the records are not amenable to be uploaded in LIMS, the person approving the discovery will return the packet to the front office by placing in Completed Discoveries filing tray, for further processing by the clerical staff.
   a. The clerical staff may FAX or e-mail the documents to the requester's attention at the District Attorneys office.
   b. If faxing or e-mailing documents to requester, a copy of the requesting letter for the attorney's reference is included.
   c. Records not amenable to electronic distribution may be placed on a CD/DVD for pick-up, and this release of records must be documented in LIMS. Create a "Log--Discovery" Case Activity in LIMS about the
existence and description of the physical file and its location. See CLER.DAT.16.

12. Discoveries may also be requested by Official Governmental Agencies (i.e. State Licensing Boards). These requests must be received in writing on official letter head. In this case only a copy of the report will be released to the requester. Note: Any requests that are extensive may be sent to County Council for review prior to releasing records.

   a. A discovery request will be open in LIMS.
   b. Staff will review report, draft-complete and admin-review the request. The hard copies will then be given back to the clerical staff.
   c. A copy of the report and the request will be sent to the requester.
   d. The original request will be attached as an administrative document to the original case record.
      i. For physical files, this can be done as a hard copy.
      ii. For electronic files, this is scanned as a request image in LIMS.

13. When staffing levels permit, discoveries are completed within ten days of initial receipt to the Lab or the due date indicated on the request, whichever is the later date.

14. The original discovery request letter is filed with the original lab report as "administrative documents". The lab number, date and initials are written on upper right-hand corner of the request letter. For electronic reports it will be imaged into the Case Attachments (e.g. ADM-01)

15. Clerical staff attaches the following to the case file as administrative documentation:
   a. The original discovery request
   b. Any documents that are NOT part of the report and notes, only if:
      i. the records are not in LIMS. If the records are uploaded as images in LIMS they need NOT be filed with the case file.
      ii. any electronic data that is saved on the CD/DVD. Create a "Log--Discovery" Case Activity in LIMS to describe the documents and its location.

B. Subpoena Duces Tecum (SDT) in Criminal case:

1. The Subpoena Duces Tecum will be handled and fee will be charged, by Records Unit, in compliance the CCCSO policy 1.05.68 on SDT. In criminal cases, the laboratory will not turn over the records to defense even if defense counsel indicates that in the subpoena Duces Tecum. The laboratory may turn over record to the clerk of court when coordinated by the District Attorney's office.
   a. If the laboratory is the participating or investigating agency in the case (if the laboratory has been involved in the analysis of the case) then the defense should get the case related records through the discovery process. Accept the SDT and give to the unit involved.
   b. Unit involved will contact the DA’s office and follow up

2. Non-extensive Criminal SDT. A non-extensive SDT would be considered the report and notes/chain of custody of laboratory analysis or a routine Draeger/Intoximeters DMT discovery on breath case. These are most commonly received for the Alcohol Unit related cases
   a. Date stamp the SDT upon receipt. Response time for criminal SDT is 15 days from the date of receipt
   b. The clerical staff will give the SDT to the proper unit to complete.
   c. The unit will complete the SDT as well as a Notification and Compliance form FSDF.10.
   d. The unit will then send the completed SDT along with the completed Notification and Compliance form to the Supervisor or Manager of the Records Unit.
   e. The unit also prepares a hard copy of the SDT and places it in an envelope addressed to the "Court Clerk".
   f. The unit then gives the envelope to the clerical staff.
   g. The clerical staff will mail the envelope to the "Court Clerk".

3. Extensive Criminal SDT
   a. Date stamp the SDT upon receipt. Response time for criminal SDT is 15 days from the date of receipt.
b. For Criminal SDT, provide the SDT to individual or Unit involved and they will contact the District Attorney's office to discuss the relevance and possibly request a motion to quash.

c. The laboratory staff will comply with the advice and direction provided by the DA's office or the County Counsel's office.

d. The unit will complete the SDT as well as a Notification and Compliance form.

e. The unit then sends the completed SDT along with the completed Notification and Compliance form to the Supervisor or Manager of the Records Unit.

f. For Criminal SDT, the unit also prepares a hard copy of the SDT and places it in an envelope addressed to the "Court Clerk".

g. The unit then gives the envelope to the clerical staff.

h. The clerical staff will mail the envelope to the "Court Clerk".

4. **Civil SDT for records:**

   a. Date stamp the SDT upon receipt. Response time for SDT is 15 days from the date of receipt

   b. For Civil SDT, provide the SDT to Manager/Supervisor may contact the County Counsel for advice or possibly request to quash the SDT. See FSD.45 for more details on sending the records and collection of fees.

   c. The civil SDT for records is mostly for Admin Per Se hearings at Department of Motor Vehicles (DMV) and are related to driving under the influence cases. The records provided will be "basic discovery material". See BA.36 & BRA.15 for the more information about alcohol related discoveries.

      i. The request for Admin Per Se DMV hearing may also be received as a discovery request directly from the defense counsel. These discoveries are not routed via the DA's office, like the criminal discovery requests.

      ii. The proper DMV SDT form (DS 3000 or equivalent) must be submitted for the laboratory to comply. Lab staff will advise the requesting party to submit the discovery request with the proper DMV SDT form when any other written discovery request is submitted for a DMV hearing. See BA.36 for more information.

   d. The SDT is provided to Alcohol Unit to comply and provide the records

   e. Alcohol Unit will complete the discovery and give the records to the clerical staff.

   f. The clerical staff will send those records to DMV and/or the attorney per the instruction written on the Admin Per Se SDT discovery request.

   g. A copy of the records may also also be sent to Supervising Hearing Officer at DMV.

5. **Civil SDT for Court appearance:**

   a. These SDTs are to be directed to the Civil Unit.

   b. The Civil Unit will collect the money required Department Policy.

   c. The Civil Unit will then send the SDT documents to the Muir Laboratory for completion (the Civil Unit will hold the money).

   d. There should be 5 days between the time the Crime Lab receives the SDT documents and the court date. The clerical staff should check the compliance date and scheduled court date to ensure the appropriate time window.

   e. The staff will complete the documents sent by Civil after the court date to record their appearance or non appearance.

END OF DOCUMENT
I. Policy: Once administratively reviewed, final reports are available for distribution. See FSD.43 for the report distribution policy.

A. Laboratory reports are routinely provided to the requesting (Primary) agency and the District Attorney's Office via the Automated Regional Information Exchange System (ARIES).

1. For Primary agencies that do NOT have access to ARIES, the original distribution will consist of sending a copy of the report.
   a. For physical or electronic copies: Create a "Log--Report Distribution (Non-ARIES Agency)" Case Activity in LIMS with the distribution information. See CLER.DAT.16.
   b. Reports must be copied or scanned for distribution by US Mail, Fax or Email to CHP Offices or agencies that do not have access to ARIES.

2. The following is a list of Agencies that have access to lab reports in ARIES (as of 7/24/18). Any agency that is not listed must have a Non-ARIES distribution.
   a. Contra Costa County, Office of the Sheriff
   Contra Costa County, District Attorney
   Contra Costa County, Probation Department
   Richmond Police
   Walnut Creek Police
   Pittsburg Police
   Concord Police
   El Cerrito Police
   Antioch Police
   Kensington Police
   Pleasant Hill Police
   Moraga Police
   San Pablo Police
   Hercules Police
   East Bay Regional Parks District
   Clayton Police
   BART Police
   Community College District
   Brentwood Police
   Danville Police
   Martinez Police
   Oakley Police
   Pinole Police
   San Ramon Police
   CHP-Martinez
   Contra Costa County, Superior Court
   Orinda PD
   Lafayette Police
   Contra Costa Fire District
   Contra Costa County, Coroner's Office

3. For agencies that cannot receive the report via ARIES because the case is confidential, restricted or prior to ARIES publication (Pre-ARIES) then these cases will be released outside of ARIES and documented. See CLER.DAT.16 for "Log--Report Distribution (ARIES Agency: CRPAR)" (Confidential/Restricted and Pre-ARIES Release) Case Activities in LIMS for electronic reports.
4. For agencies that receive a report AFTER the ARIES distribution per request or statute, for example: Department of Motor Vehicles (DMV), follow FSD.43 for copies of reports released after the ARIES distribution. See CLER.DAT.16 for "Log--Report Distribution (Non-ARIES Agency) Case Activities in LIMS for electronic reports.

   a. Alcohol reports with 23152 and 23153 CVC (California Vehicle Code) offense codes are copied and mailed to the DMV.
   
   b. All toxicology reports with 23152 and 23153 CVC offense codes are copied and mailed to the DMV.
   
   c. Coroner reports are not distributed to the DMV.

B. Confidential and Restricted Reports

   1. If they are physical copies, these reports should come to the copy table with the red flag stickers still attached. This alerts the clerical staff of the urgency/confidentiality of the report. If electronic only, the clerks will run a LIMS crystal report to identify any reports that need to be distributed.
   
   2. If multiple requests are pending for the case, do not seal original report. Hold original report, pending completion of all requests.
   
   3. Confidential and restricted reports are not distributed via ARIES. They may be picked-up by or mailed to the designated individual via U.S. or inter-office mail.
   
   4. Follow the policies and procedures in FSD.43 and QA.07 for appropriate acceptance, logging-in, marking, and sealing confidential and restricted reports. For electronic only copies, Case Activities can be made in LIMS. See CLER.DAT.16.
   
   5. Include the confidentiality or restricted warning to the Case Message in LIMS. Under the Case Info Tab right-click in the white-space between the header information and the synopsis field. Select "Message and Synopsis". Text added to the Synopsis will show up under the Case Info Tab. Text added to the Message will show up in a red box visible in all case tabs in LIMS. The highly visible case message will highlight the confidential/ restricted nature of the case.

C. Faxing/Emailing Rush Reports

   1. Solid dose drug cases and alcohol cases may be considered for "rush" analysis if there is a pending court date (court rush) or need to keep a suspect in-custody (investigative rush). When entering the request, enter this information in the Notes section, along with the requestor's name and pertinent phone/fax numbers for sending the final report.
   
   2. Any "rush" analysis usually requires emailing/faxing the final report to the requesting party, i.e. the investigating officer or District Attorney.
   
   3. For physical or electronic copies, document date and agency in the case activities "Log--Report Distribution (ARIES Agency: CRPAR)" (Confidential/Restricted and Pre-ARIES Release) in LIMS. See CLER.DAT.16.
   
   4. Fax or email reports as soon as possible, as they are time sensitive. Most fax numbers are programmed into the fax machine.

   a. If pending court date is greater than 24 hours, then the requester will be directed to get their report on ARIES.

D. Multiple Requests or Amendments

   1. Frequently reports have more than one request. This will occur if there are multiple suspects on a case, or if more than one type of analysis is requested on the same individual. i.e. alcohol analysis on a blood sample, and toxicology analysis on a urine sample.
   
   2. When filing reports with multiple requests, file the most recent request on the top. i.e. 10-123-2 will be filed on top of 10-123-1.
   
   3. When filing reports with amendments, the amendment will be on top followed by the amendment notification followed by the original request.

END OF DOCUMENT
I. Policy: The Drugs, Alcohol and Toxicology Lab clerical staff is responsible for the collection and transmittal of payroll forms to the payroll unit in the Admin building. Payroll forms primarily include Absence Report forms (ARF), Overtime cards (OT), and FMLA forms.

A. The forms are approved and signed by the supervisor or manager. The approving supervisor will deliver to the front office for proper routing.

B. The clerical staff must check forms for proper signatures, dates, and general completion.

C. Time off requests should have day/hour agreement. For example, if personnel request 5 vacation days, 40 hours should be listed on the form.

D. Payroll forms
   1. Payroll forms are submitted to the payroll clerk via inter-office mail. All payroll forms should preferably be placed in the blue payroll transmittals. When additional transmittals are needed, request these from the payroll clerk, via email. If blue payroll transmittals are not available, send them in regular inter-office mail transmittals.

   2. The payroll clerk for Forensic Services Division is Joyce Buendia. Her information is as follows:
      a. 651 Pine Street, 6th floor
      b. Martinez, CA  94553
      c. Phone: 925-335-1525
      d. Fax: 925-335-1551
      e. Email: jbuen@so.cccounty.us

   3. Mailing payroll forms to the payroll clerk on a weekly basis has been the practice at Muir lab. However, at the end of each month, more frequent mailings may be required in order to ensure payroll is posted before the cut-off dates. Faxing or emailing the forms may become necessary to further expedite their timely processing. Payroll closing dates are published and sent to all Sheriff's Department employees, via email.

E. Absence Report forms
   1. Once an approved ARF is submitted to front office from a supervisor, the Muircalendar must be updated to reflect the employee time off.

   2. Separate the ARF for distribution. The top white copy is submitted to the payroll clerk. The pink copy with the supervisor's signature is returned to the employee. These are placed in the employee's In box. The goldenrod and yellow copy can be shredded.

   3. ARFs pertaining to the Forensic Manager must be submitted to the Chief for approval and signature prior to distribution.

F. FMLA forms
   1. These forms are for time off under the Family Medical Leave Act. They are completed by a doctor, and must be submitted to the administrative assistant handling FMLA leaves at Sheriff's Admin within 15 days of the qualifying event/medical appointment. Generally the employee will have discussed the circumstances with the supervisor, and the supervisor will fax the form to the appropriate person, prior to completion by a doctor.

   2. Once the medical professional has completed the form, it will be faxed to the administrative assistant handling FMLA. The original form is sent to the payroll clerk with the corresponding ARF. If there will be a delay in getting the FMLA form from the attending physician, the ARF is submitted, with a comment in the FMLA Section, that the form will be sent upon completion.
G. Overtime cards

1. These cards are also approved by a supervisor and delivered to the front office. An Org number, for purposes of charging the overtime hours, must be selected. The org number choices are listed on the top of the form.

2. Completeness checking regarding this form would include checking for proper hours, dates, signatures, and org numbers. The overtime card is a two part form. The bottom copy is the employee copy. If not already separated by supervisor, distribute copy to employee.

H. Miscellaneous

1. Maintaining adequate supply of payroll forms is also a function of the clerical staff. Absence Report Forms and Overtime cards are stored in the supply room. As these forms are multi-part, NCR forms, they must be ordered from the C.C. County Print & Mail Department. Since printing the forms can take several weeks, inform the supervisor when supply is low.

2. Most of the single part payroll forms are available on the G Drive, in the "Group on Admin" folder, under "Forms."

3. Muir lab also maintains a small supply of some of the more commonly used forms in a drawer in the file cabinet under the copy table.

4. Any questions regarding forms should be directed to the payroll clerk.

END OF DOCUMENT
I. Policy: Opening daily mail is a function of the Laboratory clerical staff.

A. Inter-office mail
   1. Subpoenas which are received by inter-office mail are placed in the incoming subpoena tray.
   2. Mail from the Criminalistics Lab or Sheriff's Property can also be received through inter-office mail. This mail will primarily be addressed to the Forensic Services Division Chief or Manager, and distributed accordingly.
   3. Inter-office mail is also received from other Contra Costa County departments, including the District Attorney's office and Public Defender's office. These can be subpoenas, discovery requests, etc.
      a. Any U.S. Mail forwarded to the Laboratory will be date stamped and initialed upon receipt at the Laboratory.

B. U.S. Mail
   1. U.S. mail is comprised of a variety of things such as checks, bills, periodicals, discovery requests, etc.
   2. Payment checks and invoices that are received will be date stamped and initialed then placed in the hanging mail depository in the clerical area for the account clerk.
   3. Any Discovery requests, SDTs, or Evidence Transfer requests will be date stamped and initialed on the envelope and the first page of the paperwork.

C. Proficiencies
   1. When proficiency samples are received, date stamp and initial the first page of the paperwork contained inside the package. Start a chain of custody sticker.
   2. Follow any special instruction regarding storage of evidence, "to be refrigerated", as indicated.
   3. E-mail notification to the Forensic Manager/Supervisor regarding the receipt of proficiency samples.

END OF DOCUMENT
I. Policy: Non-conforming work includes any aspect of testing or work product that does not conform to laboratory policies, procedures or the agreed requirements of the customer. When non-conforming work is encountered in the Clerical Unit, action is taken to address the non-conformity or quality issue.

A. The appropriate corrective action taken is based on the type of non-conformity, the magnitude/scope of the problem, and whether the non-conformity was isolated or repetitive. When clerical staff become aware of non-conforming work they should notify their Supervisor/Manager. See FSD.15 for more information about the evaluation of non-conforming work.

1. **QAC-1 or Level 1 Corrective Action (Most Significant)**: Action taken to address a significant technical or quality issue. The non-conformity requires documentation of the corrective action per Division policy and procedure. See FSD.15 for more information.

2. **QAC-2 or Level 2 Non-Conformity**: These incidents do not cause immediate concern for the quality system but may have an isolated effect, tend to be individual events, and are addressed on a case-by-case basis. These non-conformities have the potential to be re-mediated.

   a. Level 2 non-conformities may include but are not limited to:

      i. Not following current published Clerical or Division policies and procedures.

      ii. Repeated Level 3 errors.

      iii. Transcriptional or spelling corrections made by clerical unit that require an amendment after the release of a report.

   b. Documentation of a Level 2 non-conformity will be maintained within the unit and will be evaluated by the Supervisor/Manager. The documentation should include, as applicable:

      i. Describe the quality issue. What is the problem (error or non-conformity)?

      ii. An explanation of how the quality issue occurred. Why did it happen?

      iii. An explanation of the action taken to correct or improve the quality issue. What was done to correct the problem?

      iv. An evaluation of the impact (if any) on casework, equipment, etc. How significant is the problem?

      v. Notes for any monitoring or follow-up. Was the correction effective?

3. **QAC-3 or Level 3 Non-Conformity (Least Significant)**: These incidents are unlikely to reoccur, are not systemic, and do not affect the fundamental reliability of the work product.

   a. Level 3 non-conformities may include, but are not limited to:

      i. Grammatical or Typographical Errors: spelling/grammar mistake in report or notes, or wrong agency case number or requestor in LIMS.

      ii. Correction of Chain of Custody: Location or date corrections are caught prior to release of the report.

      iii. Missing initials/date on evidence.

   b. When brought to the clerk’s attention, this type of non-conformity is typically corrected immediately by the clerk. A record of the correction may be captured by the clerk’s initials/date as outlined in Division Policy FSD.42 and FSD.43.
END OF DOCUMENT
I. Policy: The following procedure will be followed for laundry.

A. G&K Services currently holds our contract for the laundering of lab coats. Soiled laboratory laundry is collected in the plastic hamper located in the Store Room. Any lab coats that are soiled with blood will be placed in a red bag (supplied by G&K) and tied then placed in the plastic hamper. Soiled laundry is picked up on a weekly basis.

1. When collecting soiled laundry from the hamper for pick-up, ensure that the Lab Coat Log accurately reflects the coats that were sent for launder.

2. The G&K representative will pick up the laundry, and the laboratory staff giving the laundry to G&K personnel will sign G&K’s receipt (typically on a hand held device). The lab coats being released as well as the clean lab coats being received will be recorded on the Lab Coat Log. The individual making the entry will sign the log.

3. Remove the outgoing laundry bag from the plastic bag in the Store Room. Never touch soiled laundry with bare hands always wear gloves.

4. The incoming coats are placed in the wardrobe closet located in the Store Room.

5. If lab coats need to be ordered, notify the G&K representative. You will need to supply the staff member's lab coat size and name. Typically three coats are ordered for each staff member.

6. If a staff member retires or leaves the laboratory, collect their lab coats and notify the G&K representative that the coats are being returned and to cancel the account in that name. For billing purposes, it is important to return all lab coats. If a lab coat is missing but later found, notify the G&K representative and the account will receive a credit.

END OF DOCUMENT
I. POLICY  The Comparative Evidence Unit provides the following services as listed below. This detailed list for each service is not all inclusive, but is representative of what the Unit can perform. Work is only performed by Unit personnel with an active request in LIMS. Any work outside the scope of the typical tasks listed below requires Unit Supervisor approval.

A. Ballistic Imaging. Uses the IBISTRAX-HD3D system, a networked database that contain images of test-fired cartridge cases and cartridge cases from crime scenes.
   1. Determine the minimum number of firearms present at a scene based on class characteristics.
   2. Determining if a particular firearm is associated with other shooting incidents.
   3. Determining if one shooting scene is related to other shooting scenes.

B. Function testing of a firearm. Performed by test-firing the firearm when possible.
   1. Determining if a firearm is operational.
   2. Determining if a firearm has been altered.
   3. Determining if a firearm fires in fully automatic mode (machine gun).
   4. Determining if a firearm is an "Assault Weapon" as defined by California State law.

C. Make and model determination.
   1. Determining the caliber (or cartridge), construction, and manufacturer/marketer of a particular bullet or cartridge case and the general class characteristics of the rifling impressions or cycle of fire/action marks.
   2. Determining the minimum number of firearms present at a scene based on class characteristics.
   3. Determining a list of firearms that could have fired a particular bullet and/or cartridge case based on the markings left on the evidence.

D. Firearms comparisons.
   1. Determining if evidence bullets and cartridge cases were fired from a particular firearm.
2. Determining if evidence bullets or cartridge cases from one scene were fired from the same firearm as bullets or cartridge cases from another scene.

3. Determining the number of firearms present at a particular shooting incident.

4. Determining if unfired cartridges were worked through the action of a particular firearm.

5. Determining if fired cartridge cases or unfired cartridges were cycled through a magazine.

E. Presumptive firearms comparisons

1. Determining if evidence bullets and cartridge cases were likely fired from a particular firearm.

2. Determining if evidence bullets or cartridge cases from one scene were likely fired from the same firearm as bullets or cartridge cases from another scene.

3. Determining the number of firearms likely present at a particular shooting incident.

F. Serial number restorations.

1. Restoring obliterated or altered markings on a firearm.

G. Sound suppressor determination.

1. Determining if a device is a sound suppressor or silencer as defined by California State law.

2. Determining whether a suppressor has been used on a firearm.

H. Distance determination.

1. Determining the muzzle-to-target distance of a gunshot.

2. Evaluating evidence for the presence of smokeless powder particles.

I. Toolmark comparisons.

1. Determining if a particular tool is responsible for leaving marks on an item.

J. Footwear and tire print comparisons.

1. Determining if a particular shoe/tire made an impression.

2. Determining a list of possible shoes/tires that could have made an impression.

K. De-rusting (may be performed under the Ballistic Imaging or Function services).

1. Uses non-destructive chemicals (Evapo-Rust) to remove rust from firearms. Often used to unload rusted firearms.

END OF DOCUMENT
I. POLICY  The Comparative Evidence Unit handles many firearms in the course of examinations. Because of this the following firearms safety laws will be strictly adhered to in addition to SAF.32

A. The First Law of Gun Safety - The Gun is always loaded.
   
   1. Every time you handle a firearm treat it as if it were loaded. This means control the muzzle so it points in a safe direction. Do not point the gun at others or at yourself, this includes your feet. Inspect the gun to visually confirm for yourself that the gun is not loaded. Check the action, the chamber(s), the barrel, and any magazines to ensure that they are not loaded. If you are not familiar with a particular gun have someone experienced show you how it works. Even if you just handled the gun, if you pick it up check it again. When giving the gun to another person show them that the gun is safe. When receiving the gun from another check that the gun is safe. This redundancy will establish good habits and confirm that the gun is unloaded.

B. The Second Law of Gun Safety - Never point a gun at something you're not prepared to destroy.
   
   1. The best way to handle a gun is to imagine that it is loaded, that it functions perfectly, and at any moment the gun could fire. Since you are prepared for the gun to discharge it should always be pointing in a safe direction. Never allow the muzzle to sweep over yourself or someone else. Do not point the gun at any other objects that you do not want to destroy. Then if a negligent or accidental discharge does occur, it will impact in a safe area and nothing disastrous will occur.

C. The Third Law of Gun Safety - Keep your finger off the trigger until your sights are on target.
   
   1. Keep your finger outside the trigger guard until your sights are on target and you are preparing to fire. Most negligent discharges occur when the trigger is pulled before the person was prepared to fire. This occurs when the finger is placed on the trigger during reloading, holstering, drawing, movement, or when trying to clear a jam. To isolate the trigger finger from the other muscles in your hand is very difficult when they all want to contract together to hold the gun firmly. This is especially difficult under stress and anxiety. Therefore, the finger should not touch the trigger until the instant you are prepared to fire. This holds true even in a legitimate self-defense situation.

D. The Fourth Law of Gun Safety - Always be sure of your target and what is behind it.
1. Bullets can penetrate lots of things, many of which may surprise you. Identify your target before firing. If you are not sure of your target, don't fire. Just as important is what is behind your target. Make sure you have a safe impact area behind your target to stop the bullet. Bullets can travel a long way after penetrating a target. Bullets can also deflect and ricochet at amazing angles. By identifying your target and knowing what is behind it accidents will be avoided.

E. Every attempt will be made to handle firearms to preserve any evidence that may be present (finger prints, trace, biological materials); however evidence considerations will not take precedence over safety. Safety is the primary concern when handling firearms.

F. No firearm will be loaded with live ammunition while in the laboratory, except when it is about to be test fired at an appropriate location; the firearm must be pointed in a safe direction when loading prior to test firing. Dummy cartridges will be used to check function and chambering. It may be necessary to use primed cartridge cases, with no powder or bullet, to check chambers of unknown firearms. At no time will unfired ammunition be used.

G. The basic procedure for rendering a firearm safe is as follows:

1. Point the muzzle of the firearm in a safe direction.
2. Keep your finger off the trigger and outside the trigger guard at all times throughout the clearing/unloading process.
3. Remove any sources of ammunition.
4. Remove any cartridges from the chamber(s) by opening the action or cycling the action several times, if applicable.
5. Visually and physically inspect the chamber to confirm the firearm is unloaded.

H. Terminology

1. Accidental Discharge - occurs as a result of a mechanical failure of the firearm mechanism. The failure could be the result of age, corrosion, abuse, alterations, or wear. The mechanical failure leads to the firearm firing with no other outside influence.
2. Negligent Discharge - occurs as the result of operator error. The discharge could be the result of the operator unintentionally pressing the trigger, careless manipulation, or unfamiliarity with the firearm.

END OF DOCUMENT
I. POLICY  The Comparative Evidence Unit follows the policies for Evidence Handling as listed in the Division manual with the following additions and/or clarifications. All evidence will be handled and stored in a way that will minimize the possibility of loss, degradation, contamination, and deleterious change.

A. Receiving Loaded Firearms. Occasionally an inoperable and potentially loaded firearm will have to be submitted to the laboratory. The following steps need to be followed to submit a loaded firearm:

1. The agency must contact the laboratory and notify the clerks that a loaded firearm needs to be submitted (prior to bringing it to the laboratory).
2. The supervisor of the Comparative Evidence Unit or an experienced analyst from the Comparative Evidence Unit will be notified that a loaded gun is being submitted.
3. The container should be clearly marked that the firearm is loaded.
4. When arriving at the Laboratory, the Comparative Evidence Unit will be notified. An analyst from the Comparative Evidence will sign the physical chain of custody and take custody of the firearm.
5. The analyst will render the firearm safe. If it is necessary to disassemble the firearm, it will be taken to the Firearms area to be rendered safe.
6. The analyst will take notes on the actions taken to render the firearm safe if the actions involve more than simple manipulation of the firearm and magazine to verify the firearm is unloaded. These notes will be attached to the examination request.
7. Once rendered safe, the firearm will be placed into storage to be logged in as normal evidence. If the firearm was loaded, the supervisor shall be notified.
8. The analyst will complete the unloaded label.

B. Marking Evidence. The Comparative Evidence Unit follows FSD.35 with the following clarifications because marking firearms evidence is not always feasible. Ink can be used for temporary identification.

1. To identify a firearm the following information is necessary: the make, model, cartridge the firearm is chambered for, and the serial number. This is a unique identifier for that firearm. This information will be recorded in notes and reports and is sufficient to identify a particular weapon.
a. Firearms should not be scribed or have permanent markings placed on them. Adhesive labels or ink is recommended.

2. Evidence bullets and cartridge cases are small and have markings on them that are valuable for identification. These items, as well as firearms that do not have serial numbers, will have the required information marked on their proximal container.

C. **Batch Processing of Firearms.** Firearms may be batched for efficiently processing multiple ballistic imaging requests at the same time. When firearms are processed in a batch, the analyst shall document in the case record their verification that the unique information on the firearm (e.g. lab number and item number, serial number, etc.) matches that same unique information on the container prior to final packaging.

D. **Contamination Prevention.** At the request of the agency or when evidence preservation may be necessary, potential biological stains, contact DNA, and/or trace material will be collected prior to handling. See CE.08.

END OF DOCUMENT
I. POLICY The Comparative Evidence Unit adheres to the policies of the Division Manual in regards to Test Records and Test Reports with the following additions and clarifications:

A. Test Records

1. A case file in the Comparative Evidence Unit will be comprised of the administrative and technical records applicable to a particular case.

2. NIBIN Leads may be maintained in the case file or stored electronically in the LIMS Imaging module. In 2018, NIBIN Leads will be communicated to the customer with a Ballistic Lead report.

3. Communication records may be maintained in the case file or stored electronically in LIMS.

4. The date and identity of individuals making and recording observations in LIMS is maintained electronically through the LIMS audit trail.
   a. All Comparative Evidence Unit staff have the ability to view the audit trail in LIMS.

5. The technical review worksheet, CEF.14, will be used to assist with technical and administrative review on all non-ballistic imaging and non-abbreviated function tests. This form will be included in the notes or uploaded to LIMS.

B. Changes to Test Records

1. The unit adheres to division policy with the following clarifications.

2. A portion of the technical review worksheet, CEF.14, will be used to document the rejection of any observation, data, or test result.

C. General Conclusions. The Comparative Evidence Unit adheres to the Association of Firearms and Toolmark Examiners (AFTE) Range of Conclusions and Theory of Identification as it relates to firearm/toolmark comparisons with the addition of Quantitative Consecutive Matching Striae (QCMS) and photographs for documentation. The test report will communicate the basis for all conclusions, including inconclusive conclusions.

1. AFTE Range of Conclusions
a. **IDENTIFICATIONS** - Agreement of a combination of individual characteristics and all discernible class characteristics where the extent of agreement exceeds that which can occur in the comparison of toolmarks made by different tools and is consistent with the agreement demonstrated by toolmarks known to have been produced by the same tool.

b. **INCONCLUSIVE** -
   
i. Some agreement of individual characteristics and all discernible class characteristics, but insufficient for an identification.
   
   ii. Agreement of all discernible class characteristics without agreement or disagreement of individual characteristics due to an absence, insufficiency, or lack of reproducibility.
   
   iii. Agreement of all discernible class characteristics and disagreement of individual characteristics, but insufficient for an exclusion.

c. **ELIMINATION** - Significant disagreement of discernible class characteristics and/or individual characteristics.

d. **UNSUITABLE** - Unsuitable for microscopic examination.

2. **AFTE Theory of Identification**
   
a. The theory of identification as it pertains to the comparison of toolmarks enables opinions of common origin to be made when the unique surface contours of two toolmarks are in "sufficient agreement."
   
b. This "sufficient agreement" is related to the significant duplication of random toolmarks as evidenced by the correspondence of a pattern or combination of patterns of surface contours. Significance is determined by the comparative examination of two or more sets of surface contour patterns comprised of individual peaks, ridges and furrows. Specifically, the relative height or depth, width, curvature and spatial relationship of the individual peaks, ridges and furrows within one set of surface contours are defined and compared to the corresponding features in the second set of surface contours. Agreement is significant when the agreement in individual characteristics exceeds the best agreement demonstrated between toolmarks known to have been produced by different tools and is consistent with agreement demonstrated by toolmarks known to have been produced by the same tool. The statement that "sufficient agreement" exists between two toolmarks means that the agreement of individual characteristics is of a quantity and quality that the likelihood another tool could have made the mark is so remote as to be considered a practical impossibility.
   
c. Currently the interpretation of individualization/identification is subjective in nature, founded on scientific principles and based on the examiner's training and experience.

   d. The Comparative Evidence Unit uses both the traditional pattern matching approach along with QCMS as identification criteria to document comparisons. Casework will also be documented with representative digital images of the comparisons being conducted. The examiner should report the objective observations that support the findings of the toolmark examinations and should be conservative when reporting the significance of these observations. This allows the examiner to explain their reasoning for reaching
the conclusions they have. These conclusions are based on a specific comparison of individual characteristics, having eliminated any possibility of subclass influence.

3. Terminology

a. Pattern matching in toolmark comparison: The visual comparative examination of the topographical features (a configuration of a surface including its relief and the position of its man-made features) of two different toolmarks. These topographical features consist of individual peaks, ridges and furrows. Specifically, the relative height or depth, width, curvature and the spatial relationship of these features are defined for one toolmark and are then compared to the corresponding topographical features in the other toolmark. The consecutiveness of striae is an important topographical comparative feature. The comparison process is a combination of applied skill and science. The applied skill portion is the ability of an examiner to recognize agreement between patterns. This depends on an examiner's cognitive ability. This ability is acquired as an examiner uses his or her training and experience viewing the relative correspondence of known matching and non-matching toolmarks to build up an awareness of uniqueness. Although an examiner that uses pattern matching alone is unlikely to be able to pinpoint a specific number of points of correspondence as an identification threshold, he or she can recognize when the agreement present in any given comparison, whether it be striated or impressed, exceeds maximum known non-match agreement. When it does, a positive identification, to the practical exclusion of other tools, can be made. The scientific portion of the pattern match comparison is the validated premise that unique tool working surfaces leave toolmarks that can establish an identification.

b. Consecutive Striae: Parallel, side by side, contour variations within a striated toolmark.

c. Consecutive Matching Striae (CMS): Contour variations, within two different striated toolmarks, which, when compared microscopically, line up exactly with one another without a break or dissimilarity in-between.

d. Quantitative CMS (QCMS): A numerical tabulation of CMS runs. Typically, the number of matching CMS is designated by a number, followed by the letter x (e.g. 2x, 3x, 4x, etc…). Examiners in this laboratory, who locate potential matching striated toolmark areas through pattern matching, have chosen to numerically tabulate the quantity of CMS in these areas and use these tabulations as a way to describe the extent of matching CMS in any given striated toolmark comparison. These numerical counts are then compared to the results of empirical research involving tabulations of CMS in both known matching and known non-matching toolmarks. Toolmark identifications are made when the tabulated CMS runs exceed the thresholds established by empirical research. The application of QCMS criteria is not a different method than pattern matching, but is merely a quantitative way to describe the extent of striated pattern matching agreement. The use of QCMS criteria is simply an extension of traditional pattern matching.

i. QCMS Identification Criteria: A numerical standard used when making a quantitative assessment of matching CMS in a comparison of a test striated toolmark with a questioned striated toolmark. The amount of matching CMS is compared to an empirically determined numerical
threshold, which is greater than the best know non-match quantitative CMS value. When the best KNM value is exceeded, a positive toolmark identification can be made with confidence.

1. In three dimensional toolmarks when at least two different groups of at least three consecutive matching striae appear in the same relative position, or one group of six consecutive matching striae are in agreement in an evidence toolmark compared to a test toolmark.

2. In two dimensional toolmarks when at least two groups of at least five consecutive matching striae appear in the same relative position, or one group of eight consecutive matching striae are in agreement in an evidence toolmark compared to a test toolmark.

3. To apply QCMS criteria, the influence of sub-class characteristics must be eliminated.

e. Known non-matching toolmarks (KNM): Toolmarks know to have been made by different tools, or made by the same tool but deliberately placed in a non-matching position.

f. Maximum Known Non-matching Agreement in Striated Toolmarks: (a) For pattern matching alone, the ability of an examiner to recall the best agreement either personally observed, or that has been observed by others in the profession by rigorous studies, or (b) for examiners who quantitate CMS, this is a numerical way to describe the best known non-matching agreement that has either been personally observed, or has been observed by other in the profession by rigorous studies.

g. The Comparative Evidence Unit adheres to the definitions of specific firearms terms as listed in the AFTE Glossary.

4. Strength of Opinions Expressed in the Identification of Toolmarks

a. The positive identification of a toolmark is made to the practical, not absolute, exclusion of all other toolmarks. The reason why the identification is not (or identifications are not) absolute is because it will never be possible to examine all firearms or tools in the world, a prerequisite to making an absolute identification. The conclusion that “sufficient agreement” exists between two toolmarks (test and questioned) for identification means that the likelihood another tool could have made the questioned toolmark(s) in this case is so remote as to be considered a practical impossibility.

b. The phrase “practical impossibility”, which currently cannot be expressed in mathematical terms, describes an event which empirical testing and experience indicates will not occur under any conceivably relevant conditions. In the context of firearm and toolmark identification, “practical impossibility” means that based on 1) extensive empirical research and validation studies, and 2) the cumulative results of training and casework examinations that have either been performed, peer reviewed, or published in peer-reviewed forensic journals, no firearms or tools other than those identified are capable of producing marks exhibiting sufficient agreement for identification.

i. If something is impossible, it is thought to be incapable of being done, attained, fulfilled, or occurring. The opposite is true for things that are
thought to be possible.

ii. If some course of action or result is practical, it means that it is not theoretical, and that it has been shown to occur through practical experience.

iii. A practical impossibility means that through empirical research, validation studies, and practical experience, it has been shown that some course of action or result is thought to be incapable of occurring.

iv. While some courses of action or results may be thought to be theoretically possible, empirical research, validation studies, and practical experience combined has the ability to conclusively demonstrate that these courses of action or results are not possible, from a practical point of view.

5. Strength of Opinions Expressed in the Exclusion of Toolmarks
   a. Class characteristic-based exclusion: A source exclusion can only be expressed as a certainty if it is physically impossible that the items came from the same source based on an incompatibility in class characteristics.
   b. Individual characteristics-based exclusion: If the class characteristics are compatible or possibly compatible, source exclusion is only justified if it is the examiner’s opinion that there are demonstrable differences in individual and/or subclass characteristics such that the excluded toolmarks fall outside the demonstrable range of variability of marks produced by the questioned source tool.

6. Strength of Opinions Expressed for Inconclusive Toolmarks
   a. The examiner must report which sub-category of inconclusive result is reached and the basis.
      i. For example, the comparison revealed significant agreement of the individual characteristics, but insufficient for an identification. The submitted pistol may have fired the submitted cartridge case.
   b. Refer to 2d above, for additional information on the range of inconclusive results.

D. Steps Taken to Reduce Confirmation and Contextual Bias
   1. Verification
      a. Verifiers should not be told the original examiner's conclusion(s). The original examiner should only describe contextual information (e.g. test fire on the left stage, questioned evidence on the right). See CE.11, CE.12, and CE.18.
      b. Analysts should consider requesting verifications on examinations that do not require it (e.g. class eliminations).
      c. Analysts should position items on the microscope in a manner that does not indicate their conclusion before requesting verification.
   2. Case Information
      a. Analysts will not be provided police reports for non-ballistic imaging casework. If an analyst has a relevant question that may be answered by reference to a police report, the unit supervisor or another analyst will obtain
what is considered task-relevant information and share only this with the analyst.

b. Analysts should do what they can to limit their exposure to case-specific task-irrelevant information until after they have completed their examination.

E. Presumptive Comparisons

1. An examiner may make a presumptive determination on whether items were fired in the same firearm based on the individual characteristics.
   a. These determinations require documentation of the area examined and at least one photograph of the area used as the basis for the presumptive determination.
   b. These determinations are limited in nature so that the Unit can quickly provide investigative information to the submitting agency and District Attorney's Office.
      i. The extent of comparison does not reach the "sufficient agreement" threshold described in the AFTE Theory of Identification.
      ii. The evidence must be resubmitted for a full identification examination before an examiner may testify to a positive identification as described above.
   c. A report issued based on a presumptive comparison will use a different LIMS service type along with different report language to clearly differentiate a presumptive identification from a full identification.

F. Documentation of Conclusions.

1. The following should be used to document the basis for comparison conclusions:
   a. Record the class and individual characteristics used to reach the conclusion.
   b. If QCMS is used, representative CMS should be noted to document whether the comparison meets or exceeds the QCMS criteria for identification.
   c. Any photographs taken to document and support the conclusion should be referenced. Clearly identify the items depicted in each photograph.
   d. The Comparison Worksheet should be used for this documentation.
   e. It is up to the examiner's discretion as to the amount of documentation needed to support any conclusions of highly repetitive examinations of large numbers of similar evidence items.

2. For all casework, the examiner will document the observations that support their conclusions, opinions, or interpretations in the test record. Reported opinions, conclusions, and interpretations will be properly qualified and supported by the test record.

G. Evidence may need to be used for test firing. The notes will indicate that evidence was used for test firing and its disposition (typically with the original evidence submission).

H. Abbreviations can be used if they are common, defined, or in CE.05.

END OF DOCUMENT
I. The following abbreviations are approved for use in notes in the Comparative Evidence Unit.

⊥ - perpendicular to (orthogonal)
÷ - divided
// - parallel
# - number
-, (-) - negative
+, ⊕, (+) - positive
@ - at
#X - times magnification (e.g. 10X, etc.)
ADD'L - additional
AL - auxiliary lens
AMT - amount
APP - apparent, appears
AR or A/R - admin review
ASSUM - assuming
AVE - avenue, average
AVG - average
B/C - because
BET - between
BK, BLK - black
BLVD - boulevard
BPB - brown paper bag
BR, BRN - brown
B/W - between
C - contact
CAPT - captain
CB or CDBD - cardboard box or cardboard
CCME - clasp-closed manila envelope
CCSE - clasp-closed soil envelope
CD - compact disk
CE - coin envelope
CHAR - characteristics
CIR - circle
CMDR - commander
COLL - collected
COMP - comparison
CONS - conservative
CONT, CONTG, C^- containing
CONT, CONT'D - continued
CPL - corporal
CORR - corresponding
CRIT - criteria
(D) - deceased
D/I: dated and initialed
DEF - defined
DEMO - demonstrate
DES - designated
DESC - description
DET - determine(d) or detective
DI H_2O - deionized water
DIAM. - diameter
DIFF - different
DIS - distance or distance determination request
DK - dark
DVD - digital video disk
ENV - envelope
EtOH - ethanol
EVAL - evaluate
EVID, EVI - evidence
EX - example or exhibit
EXAM - examination
EXT - exterior
FCC - fired cartridge case
FIG - figure
FP or FPS - fingerprint(s)
FUN - function or function request
GRN - green
HSPB - heat-sealed plastic bag
HT - height
ID or IDE - identification or identification request
IFO - in front of
IMG - image
INCL - includes, included
INFO - information
INT - interior
INV - Investigator
IR - infrared
L - left
LAT - lateral(ly)
LF - left front
LIC - license
LP - latent print(s)
LR - left rear
LT - left, light, lieutenant
M/P - marked in part
MAG - magazine or magnification
MAN - manila
MAN ENV - manila envelope
MAT - material
ME - manila envelope
MEAS - measures, measured
MeOH - methanol
Micro - Microscopic
MISC - miscellaneous
MKS - marks
MMD - make/model determination
MS - microscope
N/A - not applicable
N/C - not collected
NEG - negative
NFE - not further examined
NNCTC - NIBIN National Correlation and Training Center
NTS - not tape sealed
OBS - observed, observation
OFC - Officer
OIS - Officer-Involved Shooting
ORTHO - orthogonal
OTO - on top of
P, PG - page
P/U - pick-up
PASS - passenger
PD - police department
PHOTO, PHOTO'D - photograph(s), photographed
PKG'D, PKGED - packaged
PB - paper bag
PLM - polarizing light microscope (microscopy)
PLPB - press-lock plastic bag
POS - positive or position
POSS - possible
POT - potentially
PROB - probably
PT - point
Q - questioned
QUANT - quantity
R, RT - right
RAC - randomly acquired characteristic
RD - road
REC, RECD, RECV'D - received
RECON - reconstruction
REF - reference
REL - relative
RPT, REPT - report
RESEEM - resembles or resembling
RF - right front
RGT - reagent
RR - right rear
RXN - reaction
(S) - suspect
SAMP - sample
SEM - scanning electron microscope
(microscopy)
SER - serial number or serial number request
SGT - sergeant
SIG - significant
SIR - shooting incident reconstruction
SM - small
SOL'N - solution
SS - stainless steel
STEREO - stereomicroscope
SUFF - sufficient
SUS, SUSP - suspect
T - test
TCBPB - tape-closed brown paper bag
TCME - tape-closed manila envelope
TF - test fire
THRU - through
TR or T/R - technical review
TS or T/S - tape-sealed
TSBPB - tape-sealed brown paper bag
TSCB - tape-sealed cardboard box
TSCE - tape-sealed coin envelope
TSME - tape-sealed manila envelope
TSSB - tape-sealed slide box
TSSE - tape-sealed soil envelope
UNK - unknown
UV - ultraviolet
(V) - victim
VEH - vehicle
VIC - victim
VIN - vehicle identification number
VIS - visual
VS - versus
W/ - with
W/I - within
W/O - without
WHT - white
WKSHT - worksheet
XFER - transfer
XR - cross-reference
XTALINE - crystalline
YEL - yellow
ZLPB, ZPLB - ziplock plastic bag

II. General Firearms Abbreviations

2D - two dimensional
3D - three dimensional
AFTE - Association of Firearm and Tool Mark Examiners
B - bullet; submachine gun/machine pistol
BBL - barrel
BF - breechface
BFM - breechface marks
BP - black powder
BUL - bullet
C - rifle-shotgun combination
CAC - California Association of Criminalists
CAL - caliber
CAP - capacity
CART, CTG - Cartridge
CC - cartridge case
CCI - CCI/Speer
CF - centerfire
CFRL - centerfire rimless
CH, CHAM - chamber
CMS - consecutive matching striae
CONV - conventional
Cu - copper
CYL - cylinder
DA or D/A - double action
D + S - double and single action
DAO - double action only
DTO - dithiooximide
EJ, EJR - ejector
EJC - ejector cutout
EJP - ejection port
ELIM - elimination
EXC - extractor cutout
EX, EXT - extractor
EXTOR - extractor override mark
F - fire
FA, F/A - firearm
FED - Federal
FP - firing pin
FPA - firing pin aperture
FPAS - firing pin aperture shear mark
FPI - firing pin impression
FRAG - fragment
FPD - firing pin drag mark
FR - feed ramp
GA - gauge
G, GM, GRM - grams
GEA - groove engraved area
GI, G/IMP, GIMP - groove impression
GMB - Glock Marking Barrel
GP - gunpowder
GR, GRN, GN - grains
GRC - General Rifling Characteristics File
GSR - gunshot residue
GSW - gunshot wound
HB - heavy barrel
HEMI - hemispherical
H&K - Heckler & Koch
H&R - Harrington and Richardson
HOR - Hornady
HS - headstamp
IBIS - Integrated Ballistics Identification System
ID - identification
IDABLE - identifiable
IMP - impression
INC - inconclusive
INDIV - individual
L - left
LEA - land engraved area
L&G - lands (L) & grooves (G)
LBS - pounds
LC - Long Colt
LI, L/IMP, LIMP - land impression
LR - long rifle
MA - machine gun
MAG - magnum, magazine
MFG - manufacturer
MGT - Modified Griess Test
MIM - Metal Injection Molding
MK - Mark
MKTED - marketed
M&P - Military & Police
NaRh - sodium rhodizonate
NSA - no significant agreement
Ni - nickel
NIBIN - National Integrated Ballistic Information Network
OBLIT - obliterated
O/C - o'clock
O-Tol - Ortho Tolidine
OR - over ride
PARA - Parabellum
Pb - Lead
PD - derringer
PI - semiautomatic pistol
POLY or P - polygonal
POS - positive
PR - revolver
PS - single-shot pistol
PX - pistol, four or more barrels
QCMS - quantitative consecutive matching striae
R - rifle (general) or right
RA - automatic/select-fire rifle
RB - bolt-action rifle
RC - carbine
RCFP - rimless center fire pistol
REM - Remington
RI - semiautomatic rifle
RL - lever-action rifle
RP - pump-action rifle
R-P - Remington Peters (Remington)
RF - rimfire
RR - revolving-action rifle
RS - single-shot rifle
S - shotgun (general) or safe
SA or S/A - single action
SB - bolt-action shotgun
S&B - Sellier & Bellot
S/C - subclass
SE - double-barrel shotgun
SI - semiautomatic shotgun
SIG - Sig Sauer; SIGARMS
SMG - submachine gun
SP - pump-action shotgun
SPL - special
S/N, SER. # - serial number
SNR - serial number restoration
SR - revolving-action shotgun
SS - single-shot shotgun
S&W - Smith & Wesson
T, TF - test or test fire
TM - toolmark
TP - trigger pull
UMC - Union Metallic Cartridge Co. (Remington)
UR - under rim
USM - unknown striated mark
WBY - Weatherby
WIN - Winchester

III. Bullet/Cartridge Construction Names

AB - AccuBond (Nosler)
B - bonded
BB - bevel base
BP - Bronze Point
BST - Ballistic Tip (Nosler)
BstST - Ballistic Silver Tip (Nosler, Winchester)
BT - boat tail
BW - brass wash
CB - cupped base
CL - Core-Lokt (Remington)
CW - copper wash
DEWC - double ended wad cutter
DPX - Deep Penetrating X (Cor-Bon)
DS - Deep Shok (Federal)
FB - flat base
FMJ - full metal jacket
FN - flat nose
FP - flat point
FPJ - full profile jacket
FR - flat recessed
FS - Fail Safe
GB - Golden Bullet (Remington)
GC - gas check
GD - Gold Dot (Speer)
GS - Grand Slam (Speer)
HB - hollow base
HC - hollow cavity
HMR - Honady Magnum Rimfire
HP - hollow point
HPJ - High Performance Jacket "Golden Saber" (Remington)
HPTNT - Hollow Point Explosive
HS - Hydra Shok (Federal)
IB - InterBond (Hornady)
IL - InterLock (Hornady)
IRREG - irregular
J or JAC - jacketed
JHP - jacketed hollow point
JSP - jacketed soft point
L - lead
LHBWC - lead hollow base wad cutter
LRN - lead round nose
LSWC - lead semi-wad cutter
LSWCHP - lead semi-wad cutter hollow point
LWC - lead wad cutter
MC - metal case
MT - Mag Tip (Speer)
NE - Nitro Express
P - pointed / plated
PAR - Partition
PL - Power-Lokt (Remington)
PP - Power-Point (Winchester)
PSP - pointed soft point
RB - round base
RBT - rebated boat tail
RL - rimless
RN - round nose
S - solid
SBT - spitzer boat tail
SF - StarFire (Eldorado)
SIL - silhouette
SJ - short jacket
SMP - semi-pointed
SP - soft point / spire point
SPT/Z - spitzer
SSPT - semi-spitzer
SST - Super Shock Tipped (Hornady)
ST - Silver Tip (Winchester)
STHP - silver tip hollow point (Winchester)
SWC - semi-wad cutter
SWCHP - semi-wad cutter hollow point
SX - Super Explosive (Hornady)
SXT - Supreme Expansion "Black Talon" (Winchester)
T - Ranger "T" series (Winchester)
TB - Trophy Bonded (Federal)
TBT - Trophy Bonded Tipped (Federal)
TBSS - Trophy Bonded Sledgehammer Solid (Federal)
TC - truncated cone
TMJ - total metal jacket (CCI/Speer)
TSX - Tripleshock X-bullet (Barnes)
TTSX - Tipped Tripleshock bullet (Barnes)
WC - wad cutter
WCF - Winchester Center Fire
WRF - Winchester Rim Fire
WRM - Winchester Rimfire Magnum
WSM - Winchester Short Magnum
WSSM - Winchester Super Short Magnum
WSUM - Winchester Short Ultra Magnum
WT - weight
X - X bullet (Barnes)
XTP - Extreme Terminal Performance (Hornady)

IV. Serial Number Reagents

AFC - Acidic Ferric Chloride
CC - Cupric Chloride
DR - Davis' Reagent
FC - Ferric Chloride
FR - Fry's Reagent
GR - Griffin's Reagent
HA - Hydrochloric Acid
NA - Nitric Acid
PH - Potassium Hydroxide
PNA - Phosphoric/Nitric Acid
SH - Sodium Hydroxide
TR - Turner's Reagent

Comparison Criteria

(+ ) - sufficient agreement for ID
(- ) - negative, sufficient disagreement for elimination
(+/-) - some agreement, but insufficient for ID
(-/+ ) - some disagreement, but insufficient for elimination
(?) - inconclusive, no agreement or disagreement

#X - number of consecutive matching striae

QCMS 3D Criteria - 2 different groups of 3X CMS, or one group of 6X CMS agreement or better.

QCMS 2D Criteria - 2 different groups of 5X CMS, or one group of 8X CMS agreement or better.

*Note: Abbreviations in this list are shown using all capital letters for readability; in practice, for most abbreviated words, lowercase letters may be used. The use of slashes, apostrophes, hyphens, periods, or the addition of a plural "s" is optional and constitutes acceptable variations of the above abbreviations. This list is not all-inclusive of many standardized, widely-accepted abbreviations which may also be used in examination documentation (e.g. mm, " for inch, ATF). While multiple terms may have the same abbreviation, the context will dictate the appropriate meaning.
I. POLICY  The Comparative Evidence Unit adheres to the Quality Assurance policies in the Division Manual with the following additions and clarifications:

A. Non-conforming work. When non-conforming work is encountered in the Comparative Evidence Unit, action is taken to address the non-conformity. Non-conforming work is an undesirable incident or problem encountered in casework, proficiency testing, or testimony. The level of corrective action taken for any non-conformity is dependent on the type of incident or problem and its severity. In general, the greater the severity or its substantive nature, the higher the level of corrective action taken. The appropriate QA Action-Correction (QAC) taken is based on the type of non-conformity, its magnitude or scope, and whether it is a single event or repetitive.

1. **QAC-1 (most significant)**: discrepancies or incidents that raise immediate concern regarding the overall quality of the Unit's work product or the competency of an examiner. These non-conformities rise to the level of significant concern for the quality system or a systemic problem within the Unit.
   
   a. Quality system non-conformities include, but are not limited to:
      
      i. Erroneous or falsified tests, results, conclusions, records, or testimony
      
      ii. Improper or deliberate misuse of reagents, methods, equipment, or evidence
      
      iii. Audit findings
      
      iv. Unsuccessful proficiency test
      
      v. Repeated QAC-2 errors
   
   b. Division policy describes the level of documentation taken to address a corrective action. See [FSD.15, QA.18, FSDF.06, FSD.44](#) for more information about the evaluation of significance, required elements of a corrective action, documentation, and retention of corrective action records.

2. **QAC-2 (somewhat significant)**: These discrepancies or incidents are not serious enough to cause immediate concern for the quality system or the Unit's overall work product, but do have an isolated affect on the work product, tend to be individual events, and are addressed on a case-by-case basis. These non-conformities are typically detected prior to the release of results and conclusions and have the potential to be remediated.
   
   a. QAC-2 incidents include, but are not limited to:
i. Improper use of controls, reagents, methods, or equipment when it is demonstrated their use did not impact the quality of work or validity of the result

ii. Lack of documentation for conclusions

iii. Repeated QAC-3 errors

b. The documentation of a QAC-2 non-conformity will be documented in LIMS. The documentation should include, as applicable:

i. A brief summary of the event, dates of analysis, lab/batch #, equipment identifier, etc.

ii. Any trouble-shooting or investigation

iii. The actions taken to correct the non-conformity

iv. Any other pertinent information or follow-up required

3. **QAC-3 (least significant):** Discrepancies or incidents that 1) do not affect the significance of a conclusion, a reported test result, or the integrity of the quality system, 2) are unlikely to recur, 3) are not systemic, and 4) do not affect the fundamental reliability of the work product.

   a. Examples of a QAC-3 non-conformity include, but are not limited to:

      i. Transcription errors

      ii. Grammatical or typographical errors

      iii. Omission errors

   b. When brought to the examiner's attention, this type of non-conformity is typically corrected immediately by the examiner. A record of the correction is captured when the examiner initials and/or dates the correction as outlined in policy (Test Record FSD.42 and Test Reports FSD.43).

B. Rejection of observations or data. The Comparative Evidence Unit adheres to division policy regarding the rejection of observations, data, and results with the following clarification:

   1. An analyst may reject their own observation or data (photographs) during the course of performing casework and not retain the photograph(s) if the rejection is documented in the test record with their initials and the date.

C. Reference collections. The Comparative Evidence Unit maintains the following reference collections:

   1. The Firearms Reference Collection contains different types of firearms to be used for reference of general operation, placement/configuration of markings (serial numbers), training, and for replacement parts necessary to test fire an evidence firearm that has missing or damaged parts. The Firearms Reference Collection is housed in a locked room with limited access within the laboratory.

   2. The General Rifling Characteristics File (GRC) is an database created and maintained by the FBI. It is used to sort through class characteristics of firearms to narrow down potential guns that could have fired evidence bullets and cartridge cases.
D. Firearms Reference Collection inventory. The Unit will maintain an electronic inventory of the laboratory's firearms collection.

1. Firearms Index Number
   a. Each firearm in the collection is assigned a unique firearm index number.
   b. The index number for firearms will consist of the Federal Bureau of Investigation National Crime Information Center code for the type of firearm, followed by the caliber or cartridge designation, and then followed by a three digit number. For instance PI-9x19-001 indicates a semiautomatic pistol, 9x19mm parabellum, number 001.

2. Description of the Inventory
   a. The master inventory for the firearms collection is maintained on the shared network drive.
   b. The following information for each firearm is contained in the inventory:
      i. Make (manufacturer)
      ii. Model
      iii. Caliber
      iv. Serial number
      v. Firearm index number
      vi. Any applicable notes

3. Updating the Inventory
   a. Each time that a new firearm is added to the collection, the Comparative Evidence Unit will update the inventory.
   b. A staff member will place the index number on the new firearm and add the required information to the inventory.
   c. A new copy of the inventory will be printed for the armory as needed.

4. Checking Firearms out of the Collection
   a. Firearms may be checked out from the collection at any time by members of the Comparative Evidence Unit for use in the laboratory, for test firing in conjunction with their casework, or for training.
   b. When firearms are checked out from the collection by staff members for more than an hour, it must be noted on the check out board (dry erase white board) in the armory. The board must indicate the staff member removing the firearm, the firearm index number, and the date of removal.
      i. If more than a few firearms are checked out by members of the Comparative Evidence Unit, a written log may be used.
      ii. When checking out a large number of firearms for a firearms safety presentation outside of the laboratory, an abbreviated inventory exists on the shared network drive with pre-selected firearms for this presentation. This inventory must be completed when checking the
firearms out, prior to leaving the outside location, and upon return of the firearms to the collection. Upon final inventory, the printed inventory sheets will be maintained by the Supervisor.

c. Firearms may be checked out by other members of the Contra Costa Office of the Sheriff for reference, training, or as visual aids for presentations. Permission must first be obtained from the Comparative Evidence Unit Supervisor or the Forensic Manager. The Firearms Reference Collection Checkout Log will be filled out with the appropriate information (including the firearm(s) checked out, and the signatures of the person checking the firearms out, from whom, and the date). When the firearm(s) are returned, the information on that transaction page will be completed (date returned, returned by, and who received them and placed them back into the collection).

i. The Firearms Reference Collection Checkout Log will be kept in the armory.

5. Annual Inventory

a. Annually, a staff member designated by the Comparative Evidence Unit Supervisor will physically inventory the firearms collection. Any firearms which cannot be located will be reported immediately to the Comparative Evidence Supervisor. The Supervisor will investigate to determine if the firearm(s) in question can be located. If a firearm cannot be located, the Chief and Manager will be notified immediately. The Chief, Manager, and Supervisor will determine what action will be taken.

b. The printed inventory used for the periodic inventory will be maintained by the Supervisor.

E. Equipment and Software that can influence test results

1. Equipment

a. A list of equipment and significant software dedicated to the Comparative Evidence Unit is maintained electronically. The list is updated when new equipment is acquired and when equipment is permanently removed from service.

b. Equipment in the inventory list is identified through a combination of asset number or serial number, manufacturer, model number, and description. Further designations may be used.

c. Equipment that provides unsatisfactory results will be removed from service and labeled with an "out of service" sign until the problem has been resolved.

d. Copies of manufacturer user manuals are maintained electronically in the unit's network folder, in PowerDMS, or on hard copy by the equipment.

e. Equipment in CE does not require intermediate checks due to appropriate calibration intervals, the infrequent use of equipment, the stability of the equipment, and the concurrent check of all equipment when conducting casework.

i. The comparison microscopes and the stereomicroscopes will have annual cleaning and preventative maintenance performed by an approved vendor.
ii. The magnification of both sides of the comparison microscopes will be checked annually, typically after their annual cleaning and inspection. They will also be checked any time the microscopes are moved or if something else happens that could alter their calibration.

iii. A stage micrometer is placed on both stages and the magnification is checked as follows for the following comparison microscopes:

1. Leica DMC: at each click stop position of the zoom objectives
2. Leica FSC: with each objective except 0.4x
3. Projectina VisionX: at all magnifications above 6.0x.
4. No significant deviation should be observed when done in this manner. Deviation is defined as significant when it exceeds the width of the lines on the scales being used. If significant deviation is observed, a microscope will not be used for casework until it is evaluated by an outside vendor and it successfully passes a magnification check.
5. The diopter adjustment on the eyepieces of both microscopes should be in the neutral position when checking magnification.

f. Any measurement devices used for critical measurements (e.g. Hott Rods for measurement of sawed-off shotgun barrels) will be calibrated by an ISO 17025 vendor. Other non-critical measurements may be performed with a standard ruler, tape measure, or digital caliper.

g. When an instrument is used for evidence on a case, the specific instrument will be noted in the test record

2. Software

a. A list of significant software for the Comparative Evidence Unit is maintained electronically with the name of the software and identifying information (serial number, firmware version, etc.)

b. No software processes are considered critical.

3. Information on services that may affect the quality of tests

a. Calibration and maintenance will be performed by laboratory staff or outside service technicians.

b. Vendors are selected based on one or more of the following criteria:
   i. Calibration services are provided by a vendor with ISO 17025 accreditation
   ii. Calibration services are provided by the manufacturer of the equipment
   iii. The laboratory has a prior history of satisfactory service with the vendor

c. Rice Lake is the Laboratory's approved vendor for calibration of the steel ruler, Hott Rods, calipers, scales, trigger pull weights, and Leica Disto. Mircotech Solutions is the approved vendor for microscope maintenance.
d. Evaluation of services will be performed by the Unit Supervisor or analysts in one or more of the following ways:

   i. Reviewing the vendor's accreditation scope document to ensure the calibration being requested is within the capability of the vendor

   ii. Performing a performance check after service

   iii. Reviewing certificates provided for other equipment

e. The unit will communicate to the vendor the requirements for the calibration/service being provided. This may be done through:

   i. A service contract

   ii. A quote for services to be provided

   iii. A letter outlining the requirements for service.

f. Acceptance of services will be conducted by the unit supervisor through a review of the calibration paperwork and certificates provided by the calibration vendor. If a calibration or service is not adequate for the unit's needs, the vendor will be contacted and a subsequent service/calibration may need to be performed.

4. Maintenance/Service Records and Intervals

   a. Records of service, repair, and calibration, along with any performance checks, are maintained by the unit. The records are accessible for review by all analysts.

   b. The equipment in the Comparative Evidence requiring calibration is listed below.

c. The digital camera (Canon 80D) and Phase One used in shoe/tire casework is considered equipment that could affect the quality of tests. No calibration is required because the cameras are checked concurrent with casework.

F. Reagents and Supplies

1. Selection and Evaluation

   a. Vendors will be evaluated on an initial and on-going basis to ensure suitability for use in testing on one or more of the following criteria:

   i. The vendor's product is specified by the technical procedures

   ii. The vendor supplies a certificate of analysis specifying the grade (e.g. molecular grade)

   iii. The vendor provides products that are forensic grade, pre-sterilized, or DNA free (e.g. sterile swabs).

   iv. The laboratory has a prior history of satisfactory service with the vendor.

   b. Typical vendors include, but are not limited to:

   i. SIGMA, Sirchie, Lynn Peavey, Safariland, Forensic Source, CSI Forensic Supply, Rice Lake, Canyon Sports, Big 5 Sporting Goods, and City Arms.

   c. Evaluations can be conducted by:

   i. Reviewing the certificate of analysis

   ii. Reviewing the product's shipping documents

   iii. Checking the product's performance through QC testing or validation

2. Ordering

   a. Orders may be placed by any member of the Comparative Evidence Unit.

   b. Any requirements for externally provided supplies will be communicated to the vendor through the Unit's purchasing documents

      i. This may include the item description, catalog number, and any specifications the Unit requires.

      1. Chemicals should be laboratory grade or higher.
2. Proprietary preparations by the same name containing the same or similar chemicals are typically suitable (e.g. magnaflux).

3. Commonly used chemicals are listed in CE.12.

c. The staff member forwards the order to someone with budget authority to obtain final approval to place the order.

d. The completed order will be forwarded to the Clerical Unit for record keeping.

3. Receiving

a. The individual placing an order will typically receive the supplies. The packaging form should be signed and dated by the individual receiving the order.

b. If the order does not conform to the Unit's requirements or if the correct product was not received, the Supervisor will be notified and the vendor will be contacted.

c. Commercial ammunition is of sufficient quality that it is assumed to be appropriate for use in casework. Any issues from laboratory-supplied ammunition will be documented in the case notes and reported to the Supervisor.

d. The signed packaging slip should be forwarded to the Clerical Unit.

4. Storage

a. Reagents will be stored based on their chemical properties; no other supplies require special storage.

5. General

a. Supplies that may affect the quality of a test include the chemicals, chemical preparations, ammunition, and equipment listed above.

b. The Comparative Evidence Unit does not have any supplies that are considered critical.

6. Reagents:

a. The Comparative Evidence Unit will maintain a Reagent Log for all reagents, including sodium rhodizonate (which is made up fresh before every use). The log will include the traceability information for all reagents (name, date, chemicals used, and manufacturer lot number). The laboratory's lot number (the preparer's initials and date of preparation of the reagent) will be noted in the test record when all reagents are used, except for sodium rhodizonate.

i. Sodium rhodizonate reagent is used to test for the presence of lead. The reagent has a shelf life on the order of 20 minutes and may have to be made several times during one examination. It will be tested with a blank and positive control during the examination and the results of these tests will be documented in the test record and in the Reagent Log.

b. Serial Number Restoration reagents do not expire and require no special storage requirements. Fresh reagents will be made when they are consumed.
The reagents are tested concurrent with each use by placing drops of them on the appropriate metals and observing the presence or absence of effervescence. Effervescence demonstrates that the reagent is performing properly. The reaction will be documented in the test record for that particular case and their use in the Reagent Log.

c. Reagents for Distance Determination examinations should be made up fresh each time they are used due to their short life span, except for the buffers and acetic acid. Photographic paper treated with the reagents for the Modified Griess Test can be stored in sealed plastic ziplock bags for extended periods of time if kept out of direct light. The reagents, treated paper, and buffers are tested at the time they are used and full documentation of the testing and validity of them will be placed into the test record for that particular case and the Reagent Log.

d. Reagents that are prepared and used for research or training should be labeled Research or Training on the bottle and are not to be used in casework. These reagents will be listed in the Reagent Log as well.

G. Administrative and Technical Review

1. The Comparative Evidence Unit will technically and administratively review all case reports and notifications.
   a. For Ballistic Imaging and Ballistic Leads, the administrative review milestone in LIMS documents completion of both technical and administrative review.

2. Technical review can be handled by any analyst authorized to perform technical review.
   a. The technical reviewer will evaluate the case notes and test report to ensure the reported conclusions are reasonable and supported by sufficient scientific data.

3. Administrative review can be handled by any analyst authorized to perform administrative review. When possible, it is preferable to have the administrative review performed by a different qualified analyst than the technical reviewer.

4. The administrative reviewer will evaluate the test record for the areas listed in FSD.18 Administrative Review. The technical reviewer will evaluate the test record for the areas listed in FSD.17 Technical Review. Additional areas for review during technical and administrative review include, but are not limited to, the following:
   a. Conformance to division and unit policy
   b. Test record requirements
   c. Accurate transfer of data from the notes to the report
   d. Presence of accurate audit trail data
   e. Documentation of the basis for the reported conclusion
   f. The verifying analyst's signature or initials (or electronic equivalent) and date as applicable
   g. Verification that when a secondary examination (e.g. presumptive blood testing, ballistic imaging entry, etc.) is performed by an individual other than
the assigned analyst, the second individual's signature or initials (or secure electronic equivalent) and date are present in the test record on the page(s) representing the second individual's examination.

H. Itemization
   A. The Comparative Evidence Unit may define a Submission containing only a firearm and its magazine as a single item of evidence. Any other items in the submission require itemization at the second level per FSD.38.

I. Conditions Requiring Work to be Halted
   1. If the Unit begins an examination but finds abnormal conditions that impact the Unit's ability to complete the work, the customer will be contacted or notified to resolve the situation. Examples include:
      a. If a firearm is chambered in an unusual cartridge for which the laboratory does not have the ammunition.
      b. If a serial number restoration could only be performed through permanent damage to the evidence.

J. Subcontracting
   1. The Unit subcontracts with ATF's NIBIN National Correlation and Training Center (NNCTC) to perform correlation of NIBIN entries. The unit supervisor will maintain records that document their approval of the laboratory's use of their results.

K. Sampling
   1. The Unit does not perform sampling because all items are typically tested. If any items are not tested, the report will clearly delineate what items were and were not tested.

L. Use of References
   1. Reference books, journal articles, headstamp guides, online resources, and other references may be used for research when conducting casework.
      a. Caution should be exercised when relying on online information. For example, information obtained from the manufacturer's website would be considered reliable while information located on an independently-run blog may require additional research.
   2. A copy of the information (e.g. page from Cartridges of the World) or notation referencing the information (e.g. Smith & Wesson's website, accessed on [date]) should be incorporated into the notes.
   3. The analyst and their technical reviewer must agree on the reliability of the information used in casework.
   4. Any unverifiable information that impacts the conclusions in the report will be appropriately qualified.

M. Proficiency Testing
   1. The CE Unit adheres to FSD.23 with the following clarifications. All inconclusive results or unexpected results will require documentation of action but not necessarily corrective action. An appropriate investigation will be conducted to determine if the issues were caused by the samples provided by the manufacturer, the test design, or
other factors. The analyst will complete another proficiency test to meet annual testing requirements.

N. Validations

1. An analyst in the CE Unit may perform validations and performance verifications commensurate with their authorization to perform casework.

O. Assuring the Quality of Tests

1. The Unit monitors the validity of results through a variety of methods, including:
   a. Annual policy review
   b. Use of quality controls in serial number restoration and distance determination casework
   c. Annual calibration of equipment
   d. Use of calibrated equipment
   e. Verification
   f. Technical and Administrative Review
   g. Proficiency testing
   h. Intralaboratory comparisons
   i. Functional checks of equipment
   j. Intermediate check of equipment

2. Each of these methods has its own interval of monitoring under its separate policy. Refer to the individual policies for the intervals.

3. If any issues are noted from the monitoring, the Supervisor will evaluate the magnitude and scope of the issue and take action. This action may documented in a quality action, updating policy or procedures, or within the test record.

4. To detect trends, data from quality actions can be reviewed.

END OF DOCUMENT
I. POLICY  The Comparative Evidence unit strives for timely examination of submitted evidence, especially the timely entry of cartridge cases into ballistic databases. Multiple LIMS requests may be opened to perform the requested work.

A. Casework is prioritized by:
   
1. Homicide cases in which the crime has
   a. just recently occurred and
   b. a suspect has not been identified or is still outstanding and
   c. the firearms examination has the potential to provide investigative leads towards the identification of a suspect.

2. Examinations of weapons from officers in officer-involved incidents.

3. Homicide investigations where investigators need examination results to take a suspect into custody.

4. Examinations done in order to meet a trial date.

5. Investigators need the firearms examination to further the investigation. These cases will be prioritized as follows:
   a. Homicides
   b. Sexual Assaults
   c. Other person's crimes and property crimes will be evaluated on a case by case basis.

6. Requests without any urgent investigative or court needs submitted by investigators or district attorneys will be prioritized as follows:
   a. Homicides
   b. Sexual Assaults
   c. General person's crimes (i.e. 211 PC) and property crimes (i.e. 459 PC) will be evaluated on a case by case basis.
B. The above list is generally followed when assigning priority of cases, but the laboratory reserves the right to reassign priorities based on evaluation of the request and staffing.

END OF DOCUMENT
I. POLICY Prior to significant handling of cartridge cases and firearms, the evidence must be evaluated for trace and biological evidence. Appropriate personal protective equipment (lab coat, gloves, and mask) shall be worn dependent on the type of examination. All examinations for trace or biological evidence will be conducted in a manner to prevent contamination. Collection of possible contact DNA or biological evidence will be performed in a controlled environment.

A. Trace and Biological Evidence Examination and Collection of Possible Contact DNA.

   1. Surface preparation
      a. When preparing to swab evidence for possible contact DNA, the swabbing area and any items used during the examination must be cleaned with a bleach solution. Clean butcher paper or absorbent pads must be placed on the surface and be changed as appropriate to prevent cross contamination.

   2. Trace evidence
      a. Examine the item for trace evidence. If trace evidence is found, document the trace evidence with notes or photographs as appropriate.
      b. Collect the trace evidence and package appropriately.

   3. Biological evidence
      a. Document the appearance and location with notes, photographs, and sketches as appropriate.
         i. If blood spatter is found on the exterior surfaces of a gun, document the spatter with sketches and/or photographs.
         ii. Examine the barrel for spatter, which may be present around the crown and in the bore. Document spatter in the bore with photographs using a borescope, if possible. Measure the distance the spatter traveled in the bore, if possible.
      b. Collect possible biological stains using swabs. See swabbing procedure under section 4 below.
         i. Document the location of sample and control swab collection in the case notes. Possible biological tissue should be removed from the surface of a weapon and placed in a sterile vial or envelope and stored frozen.
ii. The swabs should be packaged in a soil envelope to dry prior to being stored frozen. Package samples and controls separately.

c. Presumptive tests for blood may be conducted depending on the nature of the examination request. Refer to FSD.43 for policy requirements.

4. Contact DNA swabs

a. Wear proper PPE (e.g. lab coat, gloves, and mask) to prevent possible contamination of the evidence. Change gloves between handling different items of evidence.

b. Moisten the swab(s) using sterile water.

c. Rub the swab(s) rigorously over the target area. Optimally, use the entire surface area of the swab to collect as much material for potential biological testing.

d. If necessary, for non-porous surfaces, use a dry swab to collect the residual moisture from the target area.

e. For stained areas, a substrate control may be collected. Repeat the above procedure on a visually unstained area.

   i. A substrate control is not necessary when evidence collection is for contact DNA.

f. Record in the case notes the lot number of the sterile water that was used.

g. Package the swab in a properly labeled evidence envelope and allow it to dry completely.

h. Collect swabs from different areas of a gun separately. At a minimum, collect swabs from the following areas:

   i. Trigger and interior of trigger guard

   ii. Grips

      1. At times using two (simultaneous) swabs will be necessary depending on how textured the grip is or how saturated and torn the swab becomes during collection.

   iii. Slide including the front sight tip

   i. Other areas should be swabbed if commonly handled by the operator (e.g. magazine, charging handle, forestock, etc.).

j. Swabs from different items or locations must be packaged separately.

k. If collecting contact DNA swabs from cartridges or fired cartridge cases, collect one wet and one dry swab from each group of cartridges or cartridge cases based on class characteristics. For large groups of cartridges or cartridge cases (over 10), multiple pairs of wet and dry swabs may be needed. Package the swabs from a single group together in one envelope.

l. Follow all evidence itemization procedures in QA.09.

B. Firearms. All safety procedures will be followed when handling firearms and ammunition. The following should be documented on worksheets or notes, though some examinations
may take place prior to the firearm being submitted to the laboratory.

1. General Information--applicable to all firearms.
   a. Determine if the firearm is unloaded and render it safe if necessary. If the firearm is found to be loaded, notify the Unit Supervisor and Manager immediately after unloading it.
   b. Determine the type of firearm.
   c. Determine make, model, chamber, and serial number of the firearm. Record any discrepancies from secondary serial numbers and the serial number.
   d. Determine if the firearm is safe to fire.
      i. Check to ensure the bore and chamber are clear and free from damage, wear, alterations, or obstructions that could affect safety.
   e. Determine the number of lands and grooves, direction of twist, and the type of rifling (conventional or polygonal).
   f. Document any ammunition packaged with the firearm.
   g. Record the type of magazine and its stated capacity.
      i. If requested or if examining an officer's firearm, determine the magazine capacity using the magazine loading tool (if compatible) and unfired cartridges.
      ii. Count the number of cartridges as they are loaded into the magazine and then count the number of cartridges as they are removed.
      iii. A second analyst will perform a secondary check on the magazine capacity. This may be accomplished through confirming the magazine is unable to accept any more cartridges and counting the number of cartridges used by the primary analyst.
         1. If taking handwritten notes, the second analyst will initial and date the notes to document this secondary review.
         2. If using electronic notes, the initials of the second analyst may be added to the test record by either analyst.
   h. The stated capacity of the magazine may be reported in the evidence description field in LIMS. Stated capacity should be reported when it is greater than 10.
      i. Stated capacity means either manufacturing markings on the magazine that explicitly state the capacity or the highest number stamped on the magazine that is associated with an inspection hole. If unclear, no stated capacity should be reported.
   i. If tested, the capacity should be included in the body of the report.
   j. A non-metallic dowel may be used to depress the follower to determine whether or not a limiter is present (e.g. AR 30-round magazines).

END OF DOCUMENT
I. POLICY

Prior to test firing, firearms will be examined to determine that they are in normal, safe operating condition. All aspects of the firearm's mechanism will be examined prior to test firing.

A. Safety. The four laws of firearms safety specified in Comparative Evidence Manual policy CE.02 shall be adhered to when function testing and test firing firearms. These additional rules will also be enforced when test firing:

1. Safety glasses and hearing protection will always be worn when test firing.
2. Test firing will always be conducted in groups of two or more. The primary person will be the shooter and the additional person(s) will be observer(s).
3. Observers are responsible for keeping the area around the shooter clear and to help if a malfunction or accident occurs.
4. Only load the firearm when you are ready to test fire.
5. Make sure the firearm is pointed into the capture device or down range when loading and unloading.
6. If a malfunction occurs, immediately stop firing and take action to render the firearm safe. If a misfire occurs, wait at least ten seconds before checking the firearm.
7. If an accident occurs, get help for the injured party, render the firearm safe, and immediately notify a supervisor.

B. Function testing of a firearm

1. Check to make sure the firearm is unloaded by visually and physically inspecting the chamber.
2. All preliminary examinations should have been completed. See CE.08.
3. Measure the length of the barrel and the overall length of the firearm. See CE.34 for when to use NIST-traceable equipment.
4. Run a clean patch down the bore to collect residues, if appropriate. If the patch is examined, then it must be itemized and treated as evidence.
5. Determine the type of action of the firearm.
6. Check for broken firing pins, then dry fire the firearm in single-action and double-action modes, if applicable. Check the books in the library or on the internet for...
references on particular firearms if more information is needed. In order to make sure that firearms feed and operate mechanically, dummy cartridges may be used.

7. Document the functionality of safeties and controls.

8. Revolvers:
   a. Record the number of chambers in the cylinder.
   b. Check hammer in all positions.
   c. Make sure all safeties, including transfer bars, half cocks, etc. are working properly.
   d. Check the front of cylinder for chamber flares or halos and damage that may cause markings on fired bullets.
   e. Check for correlation of fired cartridge cases with halos. Check each chamber for powder residue.
   f. Check for the direction of rotation of the cylinder and that the cylinder lines up and locks in alignment with the barrel.

9. Semiautomatics:
   a. Cycle slide. Check if the firing pin is broken. Confirm that the disconnector is working, if applicable.
   b. Record the extractor and ejector configuration.
   c. Record the types of marks on the breechface and the firing pin shape and finish if an identification examination is likely.
      i. Note any vestiges of headstamp information that may remain on the breechface.

10. Rifles and Shotguns:
    a. Check bolt opening and closing. Check the disconnector in semiautomatics to make sure it is functioning properly. Check all safeties.
    b. Cycle levers to see if they operate.
    c. Check if magazine feeds properly and if there is a magazine plug.

11. Determine the trigger pull(s) of the firearm.
    a. Trigger pull weights
       i. Verify that the firearm is unloaded.
       ii. Position the barrel of the firearm vertically, with the muzzle pointed at the ceiling and the barrel perpendicular to the floor. Hold the firearm in the same position for all tests.
       iii. Begin at an estimated weight.
       iv. Rest the weighted base on a flat surface and place the elbow of the bar on the trigger where the shooter's index finger would typically rest.
          1. Ensure any trigger safety is deactivated with the placement of the bar.
v. Gently raise the firearm upwards until the weighted base is no longer supported by the flat surface. If the weight does not release the sear, add weight until the trigger-sear connection releases.

vi. Repeat to see if the weight will release the sear reliably. Remove a quarter pound to verify that you have the minimum weight that will release the sear.

vii. Step vi should be repeated a minimum of five times to find the minimum trigger pull.

viii. Record the weight.

b. The trigger pull weight should only be included in the test report upon specific request from the customer.

c. A qualitative assessment (e.g. "normal," "light," etc.) may be appropriate depending on case circumstances (e.g. determination of functionality for a case-enhancement such as a drug charge). Qualitative assessments will not be included in the test report.

12. Make casts of the barrel, chamber, gripping surface of the extractor, and breechface if appropriate for a pending identification request.

a. Use a solvent-soaked patch to clean the area being cast.

b. Label the non-silicone side of a piece of siliconized paper with appropriate case information.

c. Apply Forensic Sil or Mikrosil to the area being cast.

d. Place label paper (silicone side) against the exposed casting material.

e. Once the cast has set, carefully remove the cast from the firearm.

f. The cast should be retained with the test fires, but it can be packaged separately if used for training or reference.

13. Once it is determined that the firearm is safe, it can be test fired.

C. Selecting and preparing the proper ammunition for test firing.

1. In most cases, test firing using unaltered, live ammunition is the most appropriate method. Exceptions include, but are not limited to, the following:

a. When a firearm is deemed unsafe to test fire using live ammunition, but the function test firing needs to be performed. Primed cases can be used. Safety is the overriding concern.

2. Selection of cartridges to be test fired may include many variables

a. All firearms submitted to the laboratory will be test fired with additional ammunition for ballistic imaging.

b. If ammunition is submitted with the firearm, test firing that ammunition or similar ammunition may be done if any comparison examination has been requested. This is done to provide the best possible exemplars for the comparison (if the submitted ammunition is similar to the questioned fired components). Before testing firing submitted ammunition, the case should be
evaluated to see if the ammunition would be needed for distance
determination purposes.

c. If a questioned bullet or cartridge case is also submitted, then ammunition of
the same type as the bullet or cartridge case should be test fired as well.

d. In cases where no ammunition is submitted or no questioned bullets or
cartridge cases have been submitted, then only the laboratory-supplied
ammunition for ballistic imaging will be test fired.

3. Preparing the ammunition for test firing

a. The test firings should be numbered by scribing on the bullet ogive and
cartridge case. Ink can be used to help see the marks.

b. An index mark should be scribed at the 12 o'clock position and a mark may be
placed at the same orientation on the base of the cartridge case so proper
orientation of the index mark can be made.

c. Minimally, two cartridges of each type of ammunition in question should be
prepared. Additional test fires may be created as appropriate.

d. Record the selection and preparation of the cartridges to be test fired (e.g.
filling the nose of hollow point bullets with glue) on a Firearms Worksheet.

4. Downloading ammunition

a. On occasion it may be necessary to download ammunition so the bullet can be
recovered without damage or to allow a high-powered rifle to be fired into the
water tank without damaging the tank. The procedure for downloading
ammunition is as follows:

i. The cartridge to be downloaded must first have the bullet cleanly
removed by using a kinetic bullet puller.

ii. The powder from the cartridge case is recovered and measured on a
digital scale.

iii. About two thirds of the powder is returned to the cartridge case.

iv. Cotton is fluffed and used to fill the empty space left by the missing
powder.

v. The bullet is carefully replaced and returned to its normal position in
the case by pushing or gently tapping with a hammer.

vi. Mark the cartridge for test firing as above.

vii. Care should be taken during test firing to ensure a misfire does not
occur and that the firearm is not fired again if a bullet gets stuck in the
barrel.

viii. If the recovered bullet is damaged, another cartridge can be
downloaded using about half the powder charge.

ix. Never use less than half the normal powder charge since unsafe
pressure levels could occur.

D. Test firing the firearm

1. All safety rules will be followed when test firing.
   
a. In most casework instances, the bullet and cartridge cases need to be recovered during test firing. The CyberNational bullet recovery system is suited for this purpose.

b. The tank is located inside the Firearms Section at Summit next to the Firearms Reference Collection room. The tank should be kept filled with water to a level about even with the bottom of the internal shooting port opening and a half inch above the skimmer while the water is flowing.

c. Prior to test firing into the tank, the power on the Operators Panel will be turned on. The lid will be raised to view inside the tank to ensure that water is flowing through the filtration system, that no projectiles or fragments are present in the tank, and so that the side basket can be placed into position.

d. The red Moisture Migration Plug will be removed from the blower unit. This allows the air inside the tank to be sucked through the HEPA filtration system. The door to the room will be shut. The lid will be lowered. The blower will be turned on. Note: When the blower is on, the water filtration system will stop. (See CyberNational Operating Guide for more complete details on system). The system is now ready to be fired into.

e. The shooter and observer(s) will relocate to the front of the bullet recovery system. With safety glasses and hearing protection on, the shooter will point the firearm into the tank through the shooting port, and then load the firearm. The observer gives the all clear signal after confirming the shooter is in a safe firing position. The shooter then fires their shots directly into the water, being careful to not strike the sides or bottom of the tank.
   
i. This is a good time to make sure the safety works with live ammunition.

ii. Make sure both single and double action modes are tested.

iii. During firing, never move the firearm out of the tank or move it from a forward, slightly downward-pointing position.

f. On completion of firing, the chamber is checked to ensure all of the rounds were fired. Wait a few seconds for the air to clear out in the tank before turning off the blower. Water flow should start again.

g. Open the lid and retrieve the test fired bullets with the vacuum retrieval wand. The side basket and air hose assist in retrieval. The side basket is to be stored outside of the water tank between test firings to minimize corrosion.

h. Replace the Moisture Migration Plug. Scan the bottom one last time to locate any missed fragments. Close the lid to the tank and turn off the power.

i. During test firing firearms may become wet from the water tank. These firearms should be dried and then sprayed with WD-40 to displace water and prevent rusting.

j. All handguns using standard ammunition are safe to fire into the water tank. Rifles up to 30 carbine caliber and velocity below 2000 feet per second (FPS) can be fired into the tank without downloading. Rifles exceeding 2000 FPS may be downloaded to keep the bullets from fragmenting if needed. No armor
piercing ammunition is allowed in the water recovery tank. The system is rated to handle .50 BMG cartridges.

k. The system should be powered up and the water filtration run 3-4 hours daily during regular business hours. This keeps the system primed and the water clean.

l. The water level and chemicals should be checked weekly. The system should be drained annually and the interior cleaned before refilling. Refer to the Operating Guide for specifics on these operations.

3. Snail trap at Suite C (2099 Arnold Industrial Way, Concord)
   a. The Snail trap is located in the covered parking stall and may be used to test fire firearms when recovery of the projectile is not needed.
   b. Ensure the trap is positioned with an appropriate backdrop for safety. A ballistic vest should be worn by the shooter.
   c. Prior to test firing, Property (925-646-5877) and Concord P.D. (925-671-3220) will be notified about the use of the trap and the expected number of shots.

4. Test firing at the Sheriff's Range (12000 Marsh Creek Road, Clayton)
   a. A number of examinations may necessitate test firing at the range. For example, shotguns, automatic weapons, ricochet cases, ejection patterns, or test patterns created for distance determinations will be done at the range.
   b. Use of the range is detailed in the Sheriff's Office Policy and Procedures Manual (1.07.34) Firearms Range Use Regulations.
   c. There may be a rare situation that requires a firearm deemed unsafe to be fired with unaltered, live ammunition. In this situation, a remote firing device (Ransom Rest or vise) will be used and the firearm will be fired when all persons are safely behind a barrier. This will be done at the Sheriff's Range.

5. Canyon Sports Range (887 Howe Road Suite F, Martinez)
   a. The range may also be used for casework where recovery of bullets is not needed. Contact staff at Canyon Sports for permission to use their range.

6. If testing is performed at any location other than the laboratory, the test report must indicate where the testing was performed. See FSD.43.

7. Recovery of test-fired components
   a. At the completion of the test firing, the test-fired bullets and cartridge cases should be placed into a manila envelope marked with identifying information.
   b. Test fires for ballistic imaging purposes will be handled according to CE.16. Test fires for identification purposes will generally be itemized and packaged with the firearm.

E. Assault Weapons

1. The Unit is occasionally asked to determine whether a firearm meets the California Penal Code definition of an assault weapon. Analysts determine whether a firearm possesses the design characteristics as listed in the Penal Code. AFTE definitions
and ATF interpretations of design features are used by the unit in making this determination.

F. **Function testing of zip guns**
   1. The Unit is occasionally asked to examine zip guns. Zip guns will be examined using the same procedures listed above and in CE.08.
   2. Test firing is not required for zip guns unless necessitated by case circumstances. If needed, test firing with primed cartridge cases is the preferred method as safety is the overarching concern.

G. **Function testing of non-firearms**
   A. The Unit is occasionally asked to examine pellet guns, BB guns, and other non-firearms. These items will be examined using the same procedures listed above and in CE.08 to document the submitted item, its ability to function, its overall appearance, whether or not it is capable of firing conventional centerfire or rimfire ammunition, and other design characteristics. Trigger pull determinations are not required unless specifically requested or if appropriate based on the evidence.
   B. Test firing may be appropriate for pellet or BB guns and, if so, will be conducted using the water tank.
   C. Manufacturer information, if available, should be included in the case notes for these items and, if appropriate, in the test report.

END OF DOCUMENT
I. POLICY In many investigations, only fired ammunition components are recovered. The examination of expended bullets or cartridge cases recovered as evidence can result in the generation of a list of guns that could have been used to fire them. Occasionally an image of a firearm may be evaluated to determine the make and model of the depicted firearm.

A. Equipment. The stereoscope is typically used (with direct and oblique light) to sort fired components based on class characteristics. A comparison microscope should be used when examining multiple groups of similarly-marked items based on class characteristics (e.g. eight Remington 40 S&W cartridge cases and nine Winchester 40 S&W cartridge cases).

B. Fired Bullets. Determine the caliber of submitted bullets and, if needed, the potential firearms that could have been used to fire them. A bullet worksheet can be used to document the following examinations. The weight and measured diameter of fired bullets will not be included in the report; if determined, the nominal caliber will be included in the test report.

1. Prior to examination, the bullets should be examined for trace and biological materials. See CE.08. If necessary, the biological material should be collected.
   a. The bullet can be cleaned in a solution of water and Tergazyme or similar detergent if necessary to remove biological material and render the bullet safe to handle.
   b. Cotton swabs or a soft bristle toothbrush can be used to gently remove biological materials.

2. Note any damage to the bullet (nose, base, side) and type (abrasion, dent, fragment, impressions) along with any evidence of ricochet.

3. Determine the caliber.
   a. Measure the diameter of the base (or the least deformed area close to the base) with calipers for an approximation of the nominal caliber.
   b. If bullets are badly deformed, the following formula can be used to determine the diameter (D).
      i. \[
         \frac{(\text{Land impression width} + \text{Groove impression width}) \times (#\text{Land & Groove impressions})}{\pi} = D
      \]

      For example: If groove impressions measure 0.105" and land
impressions measure 0.115" and there are five land and groove impressions, then using the formula:

\[
\frac{(0.105 + 0.115) \times 5}{\pi} = 0.350"
\]

c. If the bullet is deformed or flattened, a rough approximation of the diameter may be determined by measuring the narrowest area near the base and the widest area near the base and averaging them.

d. Some bullets may be so deformed that only an approximation of the diameter may be made, if even possible.

4. Determine the weight.

a. Weigh the bullet on a balance and record the weight in grains. The differences in nominal caliber can often be determined by weight (1 gram = 15.432 grains).

b. If the bullet is fragmented and material is obviously missing, weigh the fragments or partial bullet and note that material appears to be missing.

c. Exercise caution when potentially dealing with bullet cores where the jacket is missing, since lead bullet cores can have a similar appearance to plain lead bullets with rifling impressions.

5. Determine the bullet type.

a. Note the bullet composition (plain lead, copper jacketed lead, brass jacketed lead, copper washed, etc.) and the bullet shape (semi-wadcutter, jacketed hollow point, full metal jacket, etc.).

b. Note construction (open base, flat point, round nose, etc.), cannelures, crimp grooves, or lube grooves. The distance between the cannelures, lube grooves, crimp grooves, and base can be measured.

c. Note any color codes or markings (military ammunition).

6. Determine the direction of twist, the number of land and groove impressions, and if the rifling is conventional or polygonal.

a. Count the number of land and groove impressions. If not possible, several options can help determine the number of land and groove impressions:

i. Search the land and groove impression measurements in the General Rifling Characteristics (GRC) File, or

ii. Use the formula provided for determining caliber (3.b. above), but solve for the number of land and groove impressions. Using the previous example:

\[
\frac{(3.14 \times .35\text{"})}{(.105 + .115)} = 4.99 \text{ or } 5
\]

iii. This is an estimate of the number of land and groove impressions and is only as accurate as the measurements.

b. The direction of twist can be determined if the bullet's land impressions slant towards the left (left-hand twist) or towards the right (right-hand twist).

c. If a bullet is badly distorted or has very shallow angled rifling, the direction of twist can be determined by determining which edge of the land impression is the driving edge. If the driving edge is on the right side of the land impression...
when viewed from the base, the bullet has a right-hand twist. If the driving edge is on the left side of the land impression when viewed from the base, the bullet has a left-hand twist.

7. Measure the land and groove impression widths when needed; if a bullet has common rifling (e.g. 6R), measuring the land and groove impression widths is at the discretion of the analyst.

   a. Place the bullet on one stage of a comparison microscope with a micro ruler marked in five thousandths of an inch on the other stage. Align the land and groove impressions on the scope, each of them at top-dead-center when being measured, and take the measurements of all discernible land and groove impressions. All measurements are made between the shoulders of the land impressions to the nearest thousandth of an inch.

   a. The GRC File is an electronic database, maintained by the FBI, of firearm class characteristics prepared by measuring fired bullets. In addition, the database includes cartridge case, firing pin, and breech face data. The latest version of the GRC File is periodically mailed to the laboratory by the FBI. The GRC File is available on the shared network drive.

   b. Enter class characteristics, such as the number of lands and grooves, the direction of twist, and the range of widths for the land and groove impressions, into the search fields for the database.

      i. Incorporating a variance of ± .005" to the range of land and groove impression measurements is good practice when a relatively wide range is observed on fired bullets.

      ii. Incorporating a variance of ± .005" to the average is good practice when a relatively narrow range is observed on fired bullets.

      iii. Using the above variance accounts for deformity of bullets, variations in widths due to wear of the barrel or tooling used to rifle it, poor obturation, and other factors.

      iv. If, based on the appearance of the rifling impressions, there appears to have been good engagement of the bullet with the rifling and the land and groove impression measurements are very consistent around the bullet, then it may be appropriate to not incorporate an additional variance to the range of measurements before searching the GRC database.

   c. The database will provide a list of the possible firearms based on the search criteria. The list generated is limited to the firearms included in the database and is therefore not all inclusive. Any reported information derived from the GRC File should be accompanied by a statement advising that the results are not all inclusive.

C. Fired Cartridge Cases. Determine the cartridge and the potential firearms that could have been used to fire it. A cartridge case worksheet can be used to document the following examinations:

1. Determine the cartridge chambering.
a. Determine the case composition (e.g. brass, nickel-plated brass, steel, aluminum, etc.) and primer composition (e.g. brass, nickel-plated brass).

b. Determine the case type (center fire, rimfire, or shotshell) and case body shape (straight rimmed, bottleneck rimless, tapered rimmed, bottleneck belted, etc.).

c. Examine the headstamp. Most commercial manufacturers imprint the chambering on the cartridge case head as part of the headstamp.

d. For any unknown caliber ammunition, such as military ammunition and some foreign ammunition, use the following steps to determine the chambering.

   i. Measure the case mouth inside diameter for a rough estimate of the caliber.

   ii. Measure all dimensions of the case (length, case mouth, case rim, case body, shoulder width, length to shoulder, etc.).

   iii. Reference the measurements to a book, such as Cartridges of the World or Ammo & Ballistics.

   iv. Any reloading manual, other firearms reference books, most ballistic software programs, and many internet sites have cartridge dimension data as well.

   v. Comparing the questioned cartridge case directly to a known cartridge case can also help to identify it.

2. Determine the cartridge manufacturer or marketer. Many companies have other companies manufacture cartridge cases for them and then imprint it with their headstamp.

   a. Examine the headstamp. Most commercial manufacturers imprint their names or symbol on the cartridge case head as part of the headstamp.

   b. Military and many foreign manufacturers do not follow this practice so other means may need to be used. The symbols and codes used in the headstamps can be referenced in a book, such as Cartridges of the World or Cartridge Headstamp Guide.

   c. The Association of Firearm and Toolmark Examiners (AFTE) website has an online headstamp guide for use by members. There are also several software programs and internet sites with this information that may be accessed.

3. Determine the class characteristics of the firearm that was used to fire the cartridge case by recording the following, if present:

   a. The shape, size, and location of the firing pin impression and firing pin aperture including firing pin aperture shear.

   b. The shape and form of breechface marks.

   c. The shape, size, and location of the ejector mark.

   d. The shape, size, and location of the extractor mark.
e. The shape, size, and location of the ejector and extractor cutouts.

f. Any magazine marks.

g. The shape and size of revolver chamber edge chamfer and star-extractor marks.

h. The presence of a firing pin drag mark, caused by either recoil-operated semiautomatics or the opening of top-break revolvers.

i. Any other chambering or action marks. These include slide override marks on cartridge rims, ejection port marks, loaded chamber indicator marks, feed ramp marks, and damage or wear in chambers impressed into cartridge cases.

j. These marks can be documented via sketching on a cartridge case worksheet and used to narrow down the type of guns from which a cartridge case was fired.

   i. Some firearms leave unique marks that can identify the firearm used (e.g. Glock and SWD firing pin impressions).

   ii. The Evofinder database and the 9mm and .380 Auto Matrixes can help to narrow down lists of potential firearms.

   iii. The GRC file contains information with respect to firing pin type, ejector and extractor position, and breechface striae type. Entering the information into the query screen will generate potential firearms.

   iv. The combination of a fired cartridge case and a fired bullet may narrow down a list of guns more than either can alone.

D. Class Eliminations

1. Source exclusions can only be expressed as a certainty if it is physically impossible that the items came from the same source based on an incompatibility in class characteristics.

   a. For example, Glock-type vs. hemispherical firing pin impressions, right-hand vs. left-hand rifling, striated vs. granular breechface marks.

2. Differences potentially due to primer hardness, normal variability due to test firing, or intentional alterations should be considered when reaching an exclusion based on class characteristics.

E. Reporting the Examination Results

1. In general, when a make and model determination is requested, two questions are asked: "What kind of ammunition was used?" and "What type of gun was used to fire the questioned bullets and/or cartridge cases?"

   a. The report should answer these questions. The cartridge and manufacturer should be indicated, though this can be done through the evidence inventory containing the headstamps. The second question is usually addressed by indicating the nominal caliber, the number of land and groove impressions, and the direction of twist. A list of potential firearms may be included in the report as needed.

2. The report should indicate the minimum number of firearms that could have been used to fire the items based on class characteristics. As needed, a "limited universe"
statement may be used. For example, "if the bullets are related to the cartridge cases, then the following firearms could have fired them."

F. Examination of Images

1. Occasionally, analysts will be asked to examine an image or video to determine if any manufacturer information can be determined from the depicted firearm. Any analyst authorized to perform function testing casework may conduct this analysis. Analysts may compare manufacturer design characteristics observed in the image with firearms from the reference collection or from other sources. The comparison of these manufacturer design characteristics provides the basis for an opinion on the manufacturer of the firearm in the image.

   a. Observations may be made on non-manufactured marks (e.g. scribed marks or damage) present in the image or video but conclusions should rarely be provided about whether the image or video contains a specific firearm because image artifacts may impact conclusions.

2. A statement should be included that the firearm may be a replica firearm as appropriate.

3. Submitted images or videos will be treated as evidence per FSD.42.01.

4. Any enhancements, other than brightness, contrast, and cropping, will be performed by the Digital Evidence Unit under a separate request.

5. The analyst can not offer an opinion on the authenticity of the image or video.

6. Images used to form conclusions should be included in the report by uploading an image to the LIMS imaging module and renaming it to begin with “REP”.

END OF DOCUMENT
I. POLICY  Firearms Identification is the scientific process of determining 1) whether or not questioned bullets and/or cartridge cases were fired in the same known or unknown firearm; and 2) whether or not unfired cartridges were worked through the action of a particular firearm.

A. Initial Documentation. The firearm, if submitted, along with fired bullets and cartridge cases shall be described in the notes or worksheets prior to comparison.
   1. This documentation includes the evaluation of the unknown item(s) to identify characteristics suitable for comparison prior to comparison to the known item.
   2. This examination may include an assessment for potential subclass influence and identification potential.
      a. This documentation may be accomplished with notes, sketches, photographs, or a combination these methods.
         i. The following are examples of this process: noting a well-striated firing pin aperture shear mark, small impressed marks with a random appearance in the firing pin impression, fine striae in a land impression, a relatively smooth breechface, etc.
      b. Nothing in this section prevents an analyst from later examining areas not evaluated at the initial documentation stage, should it be necessary.

B. Evaluation of Ammunition and Firearm
   1. Determine the type of ammunition appropriate for test-firing. For comparison purposes, the same ammunition as that in question, or as close as can be obtained, should be used in test firing.
      a. This may require test firing the ammunition that was submitted with the firearm.
      b. If no ammunition is submitted with the firearm, laboratory-supplied ammunition that is as close as possible to the submitted questioned ammunition components should be used.
      c. At least three test-fired bullets and cartridge cases should be obtained for comparison; however, two may suffice, depending on the availability of the
optimal ammunition and the reproducibility of the firearm's individual characteristics.

2. An evaluation of the tool working surfaces of the firearm shall be performed to determine if microscopic defects, apparent intentional alterations, or subclass characteristics from the manufacturing process are present. Based on this examination, any potential subclass influences on these surfaces shall be noted in the examination record. The individualization potential should also be noted.

   a. Examine the bore with a borescope, stereomicroscope, or by casting it.

      i. Determine how the rifling was produced (broach, button, hammer forging, etc…) if possible. Any subclass influence in barrels can be dependent on how the barrel was rifled.

      ii. Look for any damage, corrosion, or areas of obvious wear which may eliminate subclass influence.

      iii. Subclass marks are typically fine or coarse marks that run parallel to the rifling and run almost the entire length of the barrel without change or disruption.

      iv. In a broached or cut rifled barrel, the lands typically have no subclass influence, but there may be residual subclass characteristics in the grooves. Button and hammer forged barrels usually do not have any subclass characteristics.

      v. Be aware of heavy fouling, including powder residues, metal fouling from copper jackets, and the leading from lead bullets. This can cover up machining marks and cause differences in the individual characteristics observed on fired components.

   b. Examine the breechface, firing pin, extractor, ejector, and other areas that bullets or cartridge cases could contact. A borescope or stereomicroscope can assist with the examination.

      i. Breechfaces and firing pins formed by end mills and lathes can have concentric rings that need to be evaluated since they may be a source of subclass influence. Defects between and on the rings can help to eliminate subclass influence from the comparison.

   c. Make casts of the barrel, breechface, or other areas with Forensic Sil or Mikrosil to help evaluate the working surfaces of these tools, if needed.

   d. If it is determined that subclass characteristics are present in the toomarks being compared, the individual microscopic defects that were used to support the identification shall be noted in the examination record.

3. Initial Examination of Questioned Bullets and Cartridge cases.

   a. The questioned items should be examined and grouped according to similar class characteristics using a stereomicroscope.

   b. Once it has been determined that all class characteristics are similar for a group of questioned items (caliber, number of lands and grooves, direction of twist, widths of lands and grooves for bullets; and firing pin shape, breechface marks, ejector and extractor orientation for cartridge cases), and that an elimination based on differences in class characteristics is not possible, the questioned bullets and cartridge cases can be microscopically compared.
C. Microscopic Comparison of Bullets

1. The test-fired bullets shall be compared in a systematic manner. This is done in order to 1) assess them for individual characteristics and 2) to evaluate the reproducibility of the individual characteristics observed.

   a. Once a set of test-fired bullets has been examined, and a conclusion as to the reproducibility of individual characteristic agreement has been made and any QCMS runs noted, representative photographs must be taken of those specific areas to document the quality and quantity of agreement.

      i. The number of photographs taken to document agreement is at the discretion of the examiner, based on the quality and quantity of the agreement observed.

      ii. It is recommended that some low-power photographs be taken for orientation, as well as close-up photographs taken at appropriate magnifications to show detail well.

   b. The quality and quantity of the agreement and reproducibility of the test-fired bullets shall be documented in the notes. One of the test-fired bullets should be chosen as the representative known specimen to be used for comparison to the questioned bullets. Any and all of the test-fired bullets can be used for comparison to the questioned bullets if needed.

      i. It is possible to have test fired bullets with very poor reproducibility of individual characteristics. Some of the factors that cause this are detailed in section 2. c., below.

2. The questioned bullets shall be compared in a systematic manner.

   a. Once each questioned bullet has been compared to the test-fired bullets and a conclusion as to the quality and quantity of individual characteristic agreement has been made and any QCMS runs noted, representative photographs must be taken of those specific areas to document the agreement in those areas used to make the conclusion.

      i. The number of photographs taken to document agreement is at the discretion of the examiner, based on the quality and quantity of the agreement observed. Multiple photographs of different areas of agreement on a set of bullets may be needed.

      ii. If all the questioned bullets in a series exhibit a similar level of agreement with the test-fired bullet(s), only representative photographs of one of the questioned bullet comparisons needs to be photographed.

      iii. If no agreement is found, or disagreement is observed, photographs demonstrating the differences between the bullets are appropriate. The non-agreement or disagreement shall also be documented in the notes to support a result of inconclusive or elimination.

   b. The final conclusions reached from the comparisons shall be documented in the notes. Refer to CE.04 for details.

   c. The following factors can influence the appearance of the rifling impressions left on fired bullets and, consequently, the comparison results.

      i. Damage or wear to the firearm
ii. Bullet composition and velocity
iii. Chamber to barrel alignment (especially in revolvers)
iv. Leading and fouling of the barrel
v. Damage to the bullet causing deformation, distortion, or elimination of individual characteristics
vi. Lack of obturation of the bullet in the barrel resulting from loose fit and random bullet to barrel contact resulting in irregular rifling impressions on the bullet
vii. Poor manufacturing of the barrel
viii. Corrosion
d. In cases where no agreement or disagreement is observed, investigating the circumstances that might cause this to occur need to be considered. The following reasons can account for this:
i. Any of the factors in 2. c. i-viii above.
ii. Significant changes to the firearm from the time the questioned bullet(s) was/were fired to the time the firearm was collected.
iii. The bullets were fired from different guns.

3. Comparing questioned bullets without a suspected firearm.
   a. On occasion, evidence from the same or multiple scenes may be submitted without a firearm to determine if the evidence was all fired from the same gun.
   b. This comparison is performed in the same manner as the comparisons above, except no test fires are available for comparison.
   c. Conclusions may reflect whether or not all the bullets were fired from the same unknown gun. Caution must be exercised in eliminating the possibility of subclass influences when a gun is not available for examination.

D. Microscopic Comparison of Cartridge Cases
   1. The test-fired cartridge cases shall be compared in a systematic manner. This is done in order to 1) assess them for individual characteristics and 2) to evaluate the reproducibility of the individual characteristics observed.
      a. Cartridge cases present many potential areas with identifying marks, including: the head, the rim, and the case body. All areas should be evaluated for individual characteristics. The types of marks that are commonly encountered on fired cartridge cases from semiautomatic firearms include:
         i. Firing pin impressions
         ii. Firing pin drag marks
         iii. Breechface marks
         iv. Chamber marks
         v. Firing pin aperture marks
vi. Ejector marks
vii. Extractor marks
viii. Extractor or ejector cutout marks
ix. Cycling or chambering marks
x. Magazine marks
xi. Anvil marks (rimfire firearms only)

b. Examine the marks resulting from firing of the cartridge, such as the firing pin impression, breechface marks, chamber marks, and firing pin aperture marks.

i. Cycling marks, such as the ejector mark, extractor mark, any cutout marks, chambering marks, and magazine marks can also be examined; however, they may not be the result of firing, but from merely being cycled through the action of a firearm, especially if there are multiple sets of these marks present.

ii. Keep in mind that the presence of multiple extractor, ejector, cycling, or magazine marks on a single cartridge case may be a sign of either the original cartridge having been cycled through the same or different firearms(s) multiple times or of the cartridge case possibly being from a reloaded cartridge.

iii. Class characteristics can help sort groups of cartridge cases fired from multiple firearms into distinct groups for comparison.

iv. Use the appropriate magnification required for the area being examined.

c. Once a set of test-fired cartridge cases has been examined, and a conclusion as to the reproducibility of individual characteristic agreement has been made and any QCMS runs noted (if applicable), representative photographs must be taken of those specific areas to document the quality and quantity of agreement.

i. The number of photographs taken to document agreement is at the discretion of the examiner, based on the quality and quantity of the agreement observed.

ii. It is recommended that some low-power photographs be taken for orientation, as well as close-up photographs taken at whatever magnification is needed to show detail well.

d. The quality and quantity of the agreement and reproducibility of the test-fired cartridge cases shall be documented in the notes. One of the test-fired cartridge cases should be chosen as the representative known specimen to be used for comparison to the questioned cartridge cases. Any and all of the test-fired cartridge cases may be used for comparison to the questioned cartridge cases if needed.

i. It is possible to have test fired cartridge cases with very poor reproducibility of individual characteristics. Some of the factors that cause this are detailed in section 2. g., below.
2. The questioned cartridge cases shall be compared in a systematic manner.
   a. Once each questioned cartridge case has been compared to the test-fired cartridge cases and a conclusion as to the quality and quantity of individual characteristic agreement has been made and representative QCMS runs noted (if applicable), representative photographs must be taken of those specific areas to document the agreement in those areas used to make the conclusion.
      i. The number of photographs taken to document agreement is at the discretion of the examiner, based on the quality and quantity of the agreement observed. Multiple photographs of different areas of agreement on a set of cartridge cases may be needed.
      ii. If all the questioned cartridge cases in a series exhibit a similar level of agreement with the test-fired cartridge cases (e.g., Glock-type firing pin aperture shear marks), only representative photographs of one of the questioned bullet comparisons needs to be photographed, as long as all of the represented comparisons and conclusions were made using the same type of marks depicted in the photograph(s).
      iii. If no agreement is found, or disagreement is observed, photographs demonstrating the differences between the cartridge cases are appropriate. The non-agreement or disagreement shall also be documented in the notes to support a result of inconclusive or elimination.
   b. The conclusions reached from the comparisons shall be documented in the notes. Refer to CE.04 for details.
   c. The following marks may reproduce but may consist mostly of toolmarks that are not unique (subclass characteristics). The careful documentation of wear and defects that may exist within these marks may be used to individualize them.
      i. Circular marks on firing pins due to lathing or milling
      ii. Parallel breechface marks due to broaching
      iii. Circular breechface marks due to milling
      iv. Mold marks from metal injection molding (MIM)
   d. The following factors can influence the marks left on cartridge cases and consequently the comparison results:
      i. Hardness of the cartridge case or primer material
      ii. Differences in pressure when fired due to variations in quantity and type of propellant in cartridge
      iii. Alteration of the weapon due to wear, corrosion, and damage
      iv. Operating condition of the firearm
      v. Cleanliness of firearm (fouling build-up)
      vi. Poor quality manufacturing of the firearm
      vii. The orientation of the firearm when it is fired
e. In cases where no agreement or disagreement is observed, the circumstances that might cause this to occur need to be taken into account. Some of the factors to consider are:

   i. Any of the factors in 2. d. i-vii above.

   ii. The possibility that significant changes to the firearm may have occurred between the time the questioned evidence was fired to the time the firearm was examined.

   iii. The cartridge cases were fired from different guns.

3. Comparing questioned cartridge cases without a suspected firearm.
   a. Evidence from the same scene or multiple scenes may be submitted without a firearm to determine if the evidence was fired from the same gun.
   b. This comparison is performed in the same manner as the comparisons above, except no test-fires are available for comparison.
   c. Conclusions may reflect whether or not all cartridge cases were fired from the same unknown gun. Caution must be exercised in eliminating the possibility of subclass influences when a gun is not available for examination.

4. Comparing unfired questioned ammunition to other unfired ammunition or to test fires or questioned cartridge cases.
   a. It is possible to compare the cycling marks present on an unfired cartridge that has been cycled through the action of a firearm to other unfired ammunition or to test-fired or questioned cartridge cases.
   b. These comparisons are conducted as above, except that only those marks produced during the cycling of a cartridge through the action without firing it would be compared (i.e., magazine marks, chambering marks, ejector marks, extractor marks).
   c. Keep in mind that many of these cycling marks can be faint. The action of manually cycling a cartridge through a firearm may leave marks, but these marks are often not as distinct as those created from firing. This is due to the higher energy of the action during firing.

E. Microscopic Comparison of a Questioned Bullet to a Questioned Cartridge Case
   1. In some instances, it is possible to compare the axial straited marks that may be left on a bullet from the crimped/compressed mouth of the cartridge case it was originally loaded in to a questioned cartridge case in order to determine if they were once a single cartridge.
      a. This type of comparison is only conducted in unusual instances and the potential probative value of the examination relative to the case circumstances should be considered before proceeding.
   2. These comparisons are conducted as above, except that the axial striations on the questioned bullet are compared to striated test marks taken from the mouth of the questioned cartridge case.
      a. Test marks can usually be created by using a thin piece of sheet lead wrapped around a wooden dowel, which is then inserted into the cartridge case and withdrawn while scraping it against the edges of the case mouth.
F. Presumptive Identification

1. The same examination steps listed above should be abbreviated for a presumptive identification because the analyst is not fully evaluating whether "sufficient agreement" for identification exists between two items of firearm-produced toolmark evidence. The analyst shall evaluate the individual characteristics present on the items and determine if they indicate that the items were likely fired in the same firearm. Case documentation for Presumptive Identification cases differs from full Identification cases as follows:
   a. At a minimum, a cartridge case and/or bullet worksheet shall be completed.
   b. If a firearm is submitted, an abbreviated safety inspection is sufficient for determining if the firearm is safe to fire for the purpose of producing test fires for comparison.
   c. A comparison worksheet should be used.
   d. At least one photograph shall be used to document the microscopic agreement observed between the compared items. Photodocumentation shall otherwise conform to the requirements described above.
   e. Presumptive Identification cases resulting in a presumptive identification are subject to the same Verification, Technical Review, and Administrative Review procedures as full Identification cases.

2. A Presumptive Identification request can be converted to a full Identification request depending on the quality of the evidence submitted and the needs of the requester. The following are examples of casework unsuitable for Presumptive Identification:
   a. Evidentiary items requiring an extensive evaluation for subclass characteristics.
   b. Poorly-marked evidentiary items, such as cartridge cases or bullets, or firearms that mark test-fired components poorly.
   c. Cases requested for a pending trial.

3. Eliminations are not permitted under the Presumptive Identification service to avoid confusion between a presumptive identification and a definitive elimination. Eliminations shall be reported in a separate Identification request if needed (a related sub-request is recommended).
   a. When multiple groups exist with a positive association within one case, the correlating negative association is not considered an elimination.

G. Verification of Comparisons

1. All cases with comparison conclusions shall be verified by another qualified examiner except as noted in 2. below. This verification process does not mean the second examiner will examine each comparison made by the original examiner in a particular case; the second examiner may verify representative comparisons as determined by the original examiner (e.g. if the same conclusion is rendered by the original examiner regarding multiple items based on the same type of toolmark with good reproducibility). Verifiers shall initial and date the photographs that represent those areas directly viewed to arrive at their conclusion. The verifier should perform the Technical Review of the report and notes when finished.
a. Verification for Identification requests shall be done as contemporaneously as possible to the original examiner performing their examination. Observing the evidence on the microscope is required.

i. Presumptive identification cases must also be verified. Verification for presumptive identification cases may be conducted via photograph(s).

b. The verifier should not be told of the original examiner's conclusion. The original examiner should only describe contextual information (e.g. test fire on the left stage, questioned evidence on the right).

c. The verifier must reach the same conclusion as the examiner. Any differences in opinion should try to be resolved by the examiner and verifier. The Comparative Evidence Supervisor can arbitrate situations where agreement cannot be reached. The supervisor can decide in favor of either conclusion or send the evidence to another laboratory for arbitration if needed.

2. Eliminations based on differences in class characteristics shall be technically reviewed, but do not need to be verified. Photograph-based verification of class eliminations are permitted. Eliminations based on differences in individual characteristics as well as all identifications and inconclusive results shall be subjected to the verification process.

END OF DOCUMENT
I. POLICY  Submitted firearms may have obliterated serial number(s). The California Penal Code mandates that each local law enforcement agencies establish a plan for restoring obliterated serial numbers. The Comparative Evidence Unit will provide serial number restoration services to all client agencies.

A. Serial Number Restoration.

1. When a serial number is stamped into the metal frame of a firearm, the greatest deformation to the crystalline structure occurs nearest the bottom of the impression. All serial number restoration procedures are based on the principle that the deformed metal (strained crystalline structure) immediately below the stamping has higher density than the surrounding metal.

2. A variety of methods are available to restore an obliterated stamping.
   a. These methods include magnetic particle inspection, chemical etching, grinding and polishing, and locating hidden or secondary serial numbers. The type of metal containing the obliterated serial number dictates what methods are used.

3. Most obliteration attempts are intended to make the serial number difficult to see, but do not completely destroy its presence. On occasion the entire area where the strained crystalline structure was located is removed or destroyed and no restoration is possible.

4. Serial numbers inscribed with lasers or chemicals are usually not conducive to recovery.

B. Restoration Procedure. The ATF Firearm Serial Number Structure Guide (on the shared network drive) or a firearm of the same or similar make and model in the Firearms Reference Collection may provide the structure, the style of characters, and the orientation of the serial number.

1. Examine the firearm to see if the serial number is located in more than one location. Document the obliterated area with photographs.

2. This may involve some disassembly of the firearm to observe hidden serial numbers. Take care in dismantling the firearm to ensure that this procedure does not alter the operating condition of the firearm.

3. Examine the firearm to see if a partial serial number is visible. Use a magnifying glass or stereomicroscope as needed.
4. Clean the obliterated area. Remove anything that may be covering the serial number such as paint.

5. Use a magnet to determine whether the obliterated area is magnetic.

6. If the obliterated area is not magnetic, go to step 7. If the obliterated area is magnetic, Magnaflux can be used prior to etching. Magnaflux is a magnetic particle inspection process applicable to ferrous based metals.
   a. Lightly sand the obliterated area.
      i. Sometimes lightly sanding the obliterated area will reveal the serial number and no other work will be required.
   b. Place a magnet or the contour probe on the firearm (typically behind the area in question) so that the opposing poles are on each end of the obliterated area. Horseshoe magnets of various sizes and strengths are available. When using the contour probe, plug the probe into a power source. Start on AC current; DC current may also be used if no results are observed with the AC current. Push and hold the red button on the probe to send current through the metal.
   c. Apply a light coating of Magnaflux to the obliterated area using a disposable pipette.
   d. Tilt the firearm back and forth to see if any serial number characters appear.
   e. Take photographs of any restored characters.

7. If the serial number cannot be restored using Magnaflux, polish the area with sandpaper or a rotary tool. The surface should be carefully polished to a very smooth finish (i.e. mirror-like).
   a. Choose the coarseness of the sandpaper based on the quality of the obliterated area. If there are fine scratches or the serial number is partially visible, there is no need to begin with the coarsest grit available.
   b. Do not sand or polish the area of the serial number too deep or too long as it could be completely removed.

8. Use chemical etching to help make the serial number visible. Remember to use personal protective equipment (lab coat, gloves, and safety glasses).
   a. Pour a small amount of etchant into a beaker. Use swabs and disposable pipettes for the application of etchants. Do not use etching reagents directly from the stock bottle.
      i. Use an appropriate reagent for the metal in question. Record the lot number in the case notes.
      ii. Metals include four groups: stainless steels, carbon steels, aluminum alloys, and zinc alloys (pot metal).
      iii. See reagents section below for details on which reagents are appropriate for which metals.
      iv. Always begin the etching process with the weakest etchant and work up in strength. The etchant can also be diluted with water.
v. Carefully apply etchant onto the area in question. Light rubbing with a swab can be helpful, but the etchant should be allowed to sit on the area and react.

vi. Effervescence should be observed after application of the reagent if it is working properly; this must be documented in the notes.

b. Clean off the old etchant and reapply fresh etchant when necessary.

c. Inspect the area between each application. Use magnification if needed.

9. The obliterated area may be cleansed with acetone or water after each application of etchant, and before the application of a different etchant. The obliterated area may be repolished and etched several times. Magnaflux may be used at any time during the etching process to enhance the results if the area is magnetic.

a. Beware: Ferrous metals rust quickly when exposed to water.

10. Keep notes regarding the characters, partial characters, and sequence of appearance of characters during the examination. Take photographs of these observations during the examination.

11. If the examination is conducted over several days, cover the obliterated area with nail polish or clean thoroughly to keep the area from rusting over night.

12. Record the steps of the restoration, including partial and full characters seen after each step in case a character is removed during subsequent steps.

13. After the restoration attempt is finished, photograph the restored area with a scale.

14. Document the use of each reagent in the Reagent Log as prescribed by CE.06.

15. Apply a light coat of clear nail polish to the area to preserve it.

C. Verification

1. All serial number restorations shall be verified, except in circumstances where restoration is impossible (e.g. the plate that contains the serial number has been removed).

2. The verifier should not be told of the original examiner's conclusion. The original examiner should only describe contextual information (e.g. six characters).

3. The verifier must reach the same conclusion as the examiner. Any differences in opinion should be resolved by the examiner and verifier, if possible. The Comparative Evidence Supervisor can arbitrate situations where agreement cannot be reached. The supervisor can decide in favor of either conclusion or consult additional examiners.

D. Reagents.

1. Chemical Etchants. The following is a list of etchants and the types of metals they should be used on.

   a. Ferrous Metals (Steels, Magnetic) - Fry's Reagent, Turner's Reagent, 25% Nitric acid, Davis Reagent, Griffin's Reagent (stainless steel).

   b. Non-Ferrous Metals (Aluminum, Non-Magnetic) - Ferric Chloride, Cupric Chloride, Acidic Ferric Chloride, 10% Potassium Hydroxide, 10% Hydrochloric acid, 10% Sodium Hydroxide.
c. Pot Metal (Zinc, Non-Magnetic) - Phosphoric acid/Nitric acid, 10% Hydrochloric acid, and 10% Potassium Hydroxide.

2. Reagent Preparation. Always add acid to water when preparing reagents. All reagent preparation should take place in a fume hood. Use care when handling strong acids, bases and hazardous chemicals. Document the preparation of all reagents in the Reagent Log.

Fry's Reagent
90g cupric chloride (CuCl₂)
120ml hydrochloric acid (HCl)
100ml distilled water

Turner's Reagent
2.5g cupric chloride (CuCl₂)
40ml hydrochloric acid (HCl)
25ml ethyl alcohol
30ml distilled water

25% Nitric acid
25ml nitric acid (HNO₃)
75ml distilled water

Davis' Reagent
5g cupric chloride (CuCl₂)
50ml hydrochloric acid (HCl)
50ml distilled water

Griffin's Reagent
30g cupric chloride (CuCl₂)
30ml hydrochloric acid (HCl)
120ml methanol (MeOH)
30ml distilled water

Ferric Chloride
25g ferric chloride (FeCl₃)
100ml distilled water

Cupric Chloride
5g cupric chloride (CuCl₂)
3ml nitric acid (HNO₃)
100ml distilled water

Acidic Ferric Chloride
25g ferric chloride (FeCl₃)
25ml hydrochloric acid (HCl)
100ml distilled water

10% Potassium Hydroxide
10ml potassium hydroxide (KOH)
90ml distilled water

10% Hydrochloric acid
10ml hydrochloric acid (HCl)
90ml distilled water

10% Sodium Hydroxide
10ml sodium hydroxide (NaOH)
90ml distilled water

10% Nitric acid (Zinc Alloy B)
10ml nitric acid (HNO₃)
90ml distilled water

Phosphoric/Nitric acid (Zinc Alloy A)
98ml 85% phosphoric acid (H₃PO₄)
2ml nitric acid (HNO₃)

END OF DOCUMENT
I. POLICY  Sound Suppressors or "silencers" are submitted to the laboratory to determine if the device meets the definition of a sound suppressor by design.

A. General Information

1. A silencer, according to section 17210 of the California Penal Code, is any device or attachment of any kind designed, used or intended for use in silencing, diminishing, or muffling the report of a firearm. The term "silencer" also includes any combination of parts, designed or redesigned and intended for use in assembling a silencer or fabricating a silencer and any part intended only for use in such assembly or fabrication. The preferred term for a silencer is "sound suppressor".

2. Sound suppressors are designed to reduce the muzzle blast, which is the primary source of noise in the discharge of a firearm. A sound suppressor works by controlling the expansion and release of gases, typically through the use of a series of chambers or baffles. A sound suppressor may also include design elements to cool the gases, which lowers the pressure and volume of the gas. Some sound suppressor designs also include sound dampening material. These functions are used in both commercial and improvised sound suppressors.

3. The initial laboratory examination will be to determine if the device is commercial or improvised. Commercial silencers will typically be narrow cylinders with internal baffles and absorbing material such as steel wool. The device may be threaded so that it screws onto the end of a threaded barrel. The sound suppressor may also be permanently attached to the barrel. In such cases the barrel may be ported or drilled and the expansion chamber fits as a shroud over the barrel and may be filled with sound absorbing materials.

4. Improvised sound suppressors may use materials such as beverage containers, lawn mower mufflers, and other items. Since these devices may have little modification, it may be difficult to identify them as sound suppressors. Likely modifications to most improvised sound suppressors include a point of attachment, the use of filler material, and the presence of a bullet exit hole at the end of the device.

B. General Examination.

1. The device should be examined and photographs should be taken to document its appearance and condition.
2. The muzzle, breech end, and interior should be examined to see if evidence is present that indicates the device was used on a firearm. The following items may be present:
   a. Partially burnt smokeless powder particles.
   b. Soot from smokeless powder combustion.
   c. Lead or copper transfer from bullets.

3. Gunshot residue may also be collected for subsequent testing.

4. Determine if the suspected suppressor is a commercial or improvised device. This can usually be determined by the presence and quality of manufacturing marks or the use of commonly available materials.

5. Determine if the device has the construction or parts of a typical sound suppressor. Books in the library can be used for reference. The following items may be present:
   a. Expansion chambers to capture heated gases.
   b. Internal baffles to slow down and cool gases.
   c. Packing material to absorb heat, or slow down and cool gases.
   d. Ports or holes in the barrel or sound suppressor that redirect gases into the sound suppressor.
   e. Baffles typically made of rubber that keeps gases inside the device.
   f. A mechanism to attach the device to a firearm.

6. If possible, disassemble the sound suppressor to show the internal parts and construction. Do not disassemble the sound suppressor if the disassembly may render it inoperable. Commercial devices are usually easy to disassemble. Improvised devices may be difficult to disassemble without rendering them inoperable. Photographs of the disassembled device should be taken for documentation.

7. The digital X-ray machine at the Coroner's Office can be used to document the internal construction of commercial or improvised sound suppressors that cannot be disassembled.

8. If test firing through the device is needed, check the interior for obstructions before test firing.
   a. All safety rules will be followed when examining and test-firing suppressors.

9. If a firearm is submitted with the sound suppressor, they should be assembled to ensure that the device aligns with the barrel of the firearm.

END OF DOCUMENT
I. POLICY  Distance determination examinations rely on gunshot residues that are ejected from the barrel of a firearm when it is shot. The distance between the muzzle and a target may be important in an investigation.

A. General Information.
   1. Gunshot residue (GSR) consists of smokeless powder particles, soot, and condensed metallic vapors. GSR generally travels in a cone-shaped pattern from the muzzle when a firearm is discharged. The vapors are projected as a cloud that may have the same diameter at more than one distance from the muzzle. GSR is usually deposited at close ranges.
   2. Gunshot residue patterns generally increase in diameter and decrease in density with increasing range. GSR patterns can be used to determine muzzle to target distance. The evidence pattern should be duplicated and bracketed with test patterns. The maximum distance of detectable gunshot residue can also be determined.
   3. Clothing and skin are the most likely targets for a distance determination, but sheetrock, wood, paper, and other materials may also be examined.

B. General Examination.
   1. The area in question should be examined for bullet holes and gunshot residue. Use a stereomicroscope as necessary. A description of any damage and gunshot residue along with their locations will be recorded in the notes. Photographs should be taken for documentation.
      a. Suspected holes in a garment should be examined. They may have a clean cut or torn, ragged appearance. Factors to consider include:
         i. Bullet wipe on the margin of the hole.
         ii. Searing or melting of the fabric or fibers in or around the hole.
         iii. Soot and smoke around the periphery of the hole.
         iv. Particles of partially burnt or unburnt smokeless powder on or embedded in the weave of the fabric.
         v. Pieces of lead, copper, or other material from a projectile.
      b. Suspected bullet holes in a person's body should also be examined. In addition to the above factors, the following factors should be considered:
i. Tattooing - when the particles of smokeless powder embed themselves in the skin.

ii. Stippling - when the particles of smokeless powder strike the skin, but do not embed. They leave red marks on the skin.

2. All gunshot residue patterns should be examined and documented with photographs including a scale. Some garments may have blood stains that may conceal the GSR pattern.

   a. The size, density, and components of the gunshot residue deposit should be described in the examiner's notes.

      i. Presence of sooting.

      ii. Presence of scorching or searing. This includes melted fabric or burns on the skin.

      iii. Visible smokeless powder particles.

      iv. Visible lead, copper or other bullet material fragments.

3. Infrared photographs or imaging shall be used to distinguish gunshot residue patterns unless mitigating circumstances exist. Images taken with infrared equipment creates contrast between GSR patterns and dark colored clothing. Monochrome images taken with infrared filters turn dark dyes and blood into lighter shades of gray while leaving GSR patterns dark.

   a. Items may be photographed using a digital camera approved for such use and the appropriate lens filter(s).

   b. High intensity lamps may be used for lighting.

4. Another method for enhanced visualization of the smokeless powder pattern is called, "pinning". Use the stereomicroscope to locate GSR particles. It may be necessary to look into the weave of the fabric to locate imbedded particles.

   a. Place the garment on a sheet of cardboard as a backing. Using colored stickpins that contrast in color to the garment, mark the location of each powder grain.

   b. This technique is useful when marking the location of only a few powder grains on a garment. Different colored stickpins can be used to distinguish between different or overlapping patterns.

   c. The shape and size of the pattern should be described in the notes and photographs can be taken for documentation.

5. In many cases, the enhanced pattern is now ready for direct comparison to test patterns produced with a suspect firearm and ammunition without any chemical enhancement. See below for test pattern preparation.

6. In cases where the type of firearm has been identified but was not recovered, test patterns can be produced with the same make and model of firearm obtained from the laboratory reference collection.

7. In a case where the type and caliber of the firearm is not known, general conclusions can be made about the distance from the firearm to the target. However, the
examiner should proceed with caution and use conservative ranges based on his or her experience with this type of evidence and reference materials.

8. In a case where the presence of GSR is important, general conclusions can be made about the presence of smokeless powder particles based on their appearance, morphology, and susceptibility to being burned.
   a. The laboratory does not have the ability to examine for GSR particles based on their elemental composition, but can sample an item for GSR particles for subsequent elemental analysis by an outside laboratory as needed.

9. Lead test kits may be used to test for the presence of lead.

10. If appropriate, a representative gun powder particle may be burned in the fume hood to confirm that it is ignitable.

C. Making Test Patterns.

1. Test patterns are produced for direct comparison to the questioned pattern.
   a. The same firearm and ammunition should be used if available.
   b. White cotton or cotton and polyester blend cloth targets, usually 6, 12, or 18 inches wide are fastened to clean cardboard backs. GSR patterns are easily observed on the white cloth.
      i. Cardboard targets from the Sheriff's Range may be used to hang the targets; however, clean cardboard should be used as the backing so no contamination from the range occurs.
   c. The targets are shot with the firearm and ammunition combination in question at several known distances.
      i. Typical distances are hard contact, loose contact, 1, 3, 6, 9, 12, 15, 18, 24, 36, 48, 60, and 72 inches. Other distances can be used as necessary and distances can be omitted if appropriate.
      ii. At a minimum, create patterns that are bigger, smaller, and similar in appearance as the evidence pattern. This is known as "bracketing".
      iii. Establishing the maximum range that gunshot residues can be detected may be useful. This requires bracketing out to a distance where no residues, other than bullet wipe, are visible on the target.
   d. Each target is hung on a target stand.
   e. Position the appropriate approximate distance for the firearm using the Leica Disto held parallel to the bore and even with the muzzle. The Leica Disto will not be placed in front of the muzzle at any time. Once the appropriate distance is set, the shooter loads a single cartridge and secures the firearm in a Ransom rest or Manfrotto Variable Friction Magic Arm.
   f. The observer takes and records a final measurement with the Leica Disto held parallel to the bore and even with the muzzle. This measurement should be within 0.25 inches of the targeted distance.
      i. The use of the device is to hold the firearm in place while the muzzle-to-target distance is measured; the shooter should have a good grip on the firearm to control recoil.
g. The shooter test fires the firearm, using good shooting techniques to control recoil and not relying on the device to control recoil. All firearm safety rules will be followed. This does not apply when using the Ransom Rest.

h. The test patterns are packaged and transported back to the laboratory for direct comparison. The patterns should be interleaved with clean pieces of paper or cardboard to prevent cross-contamination of the patterns.

i. Not all conditions will be known for testing, including environmental conditions and exact positions of the target, firearm, or people involved.

2. Comparison-quality photographs of the test patterns should be taken with a scale to document the patterns. The photographs may be used for comparison.
   a. Describe and record the size, density, and components of the gunshot residue test patterns in the notes.

3. For the most part, white cotton or cotton blend fabric will work for most test patterns. A special occasion could arise where target material with similar properties (leather or suede) needs to be used.
   a. If possible try to purchase a similar fabric with similar properties to use as the test pattern material. Several test shots should be made into the fabric to demonstrate that the purchased fabric can produce patterns similar to the pattern observed on the evidence garment.
   b. If the material is not available and the attorneys in the case and the Firearms Supervisor agree, then the actual garment can be used for test patterns. This should only be in very rare cases.

D. Comparison.
   1. The known test patterns may be compared directly to the questioned pattern prior to chemical enhancement.
   2. Compare the size, density, and components of the GSR patterns between the test targets and the questioned item.
      a. The components are soot, smoke (vaporous residues), searing or scorching, and smokeless powder particle distribution.
   3. Bracket the questioned pattern with a smaller and a bigger test pattern. There should be a test pattern that is similar in size, density, and components to the questioned pattern. For example, with a 6-inch evidence pattern the 3-inch test pattern is smaller; the 12-inch test pattern is bigger, while the 6-inch test pattern is similar.
   4. Chemical enhancement can also be done to the evidence and test patterns to gain additional information. Chemical enhancement procedures are listed below.
   5. Photographs of injuries can be compared to test patterns if accurate photographs including a scale are available.

E. Chemical Enhancement.
   1. The evidence and test targets can be chemically processed for the presence of nitrites and lead residues. We use the Modified Griess test and the Sodium Rhodizonate test to develop these patterns.
a. The location of the bullet holes and other landmarks should be marked on the test papers for orientation prior to testing.

b. Comparison-quality photographs should be taken to document the tests.

c. The same tests should be performed on both the evidence item and the test targets.

2. The Modified Griess test for nitrite compounds. Chemical reagent descriptions and preparation instructions are listed in section G.

a. Modified Griess test for porous surfaces:

i. Add a drop of acetic acid onto a sodium nitrite swab and mark the corner of the treated paper with the swab. Use this mark to determine if the treated paper is reacting to nitrites.

ii. Place the test pattern or evidence questioned-side down onto the treated surface (emulsion side) of the treated paper. Cover the test pattern or evidence with cheesecloth soaked in 15% acetic acid.

iii. Apply heat with an iron. The acetic acid steam will transfer the nitrites to the treated paper and produce an orange-colored pattern.

b. Modified Griess test for thick or non-porous surfaces:

i. Moisten the treated paper with the acetic acid, place the test pattern or evidence questioned side down onto the treated paper and apply heat with an iron to the back of the treated paper.

ii. Be careful not to make the papers too saturated with acetic acid because the patterns may be distorted.

iii. Be careful with the iron so that the item being tested does not burn or melt.

3. The Sodium rhodizonate test for lead. Chemical reagent descriptions and preparation instructions are listed in section G.

a. Sodium rhodizonate transfer method. The transfer method is most useful on dark colored or bloodstained items.

i. Place a mark with a known lead item on a piece of filter paper prior to moistening it with acetic acid.

ii. Place the moistened filter paper onto the test pattern or evidence.

iii. Place a sheet of dry filter paper on the moistened filter paper and apply heat with an iron

iv. Remove the filter papers and spray the acetic acid moistened filter paper with the sodium rhodizonate solution.

v. Lead, barium, and strontium reacting with the sodium rhodizonate will produce a pink to red color. This color lasts a few minutes and then begins to fade.

vi. Document the reaction with notes and photographs.
vii. The moistened filter paper may be sprayed with a tartrate buffer solution to reduce the background discoloration.

viii. The moistened paper may be sprayed with 5% HCl to confirm the presence of lead. The pink to red color will change to a purple and blue color if lead is present.

ix. Photographs should be taken soon after spraying to document the test.

x. The moistened filter paper can also be sprayed with a one step buffer and fixer solution of potassium chloride and HCl. This reduces the background orange color and turns the pink to red color to purple and blue.

b. Sodium rhodizonate direct method. The direct method can be used when testing light-colored clothing or non-porous items such as sheet metal, glass, or plastic.

i. Place a mark with a known lead standard on a piece of filter paper and spray the filter paper with the sodium rhodizonate solution to test the reagents.

ii. Spray the item in question with the sodium rhodizonate solution.

iii. Spray the item with the buffer-fixer solutions as needed.

iv. Document the tests with notes and photographs. Photograph immediately to document the result before chromophoric reactions fade.

4. Comparison of chemically enhanced patterns.

   a. The chemically developed patterns should be compared to the evidence.

   b. If the test patterns do not sufficiently bracket the evidence pattern, more test patterns may be made and chemically enhanced.

F. Conclusions.

1. Care must be taken when reporting conclusions for distance determinations. Many variables and factors need to be considered when making a conclusion.

   a. Weather may disturb GSR. Strong wind may blow GSR particles away. Rain may wash away nitrites.

   b. GSR can be unintentionally removed from evidence. Paramedics performing CPR or cutting garments may knock GSR off. Handling of evidence or the passage of time between the shooting and the evidence collection may cause GSR to fall off of the evidence.

   c. Clothing saturated with blood or other chemicals can interfere with chemical tests.

   d. Intervening objects, including folds in clothing, between the muzzle and the target can cause obstructed patterns.

   e. Multiple shots may create multiple GSR patterns

   f. The surface may not be conducive to the deposition of gunshot residue.
g. The evidence may have a curved or irregular surface that may distort the GSR pattern.

h. The shooter or target may have been moving while the GSR was deposited.

i. Photographs or other records of GSR patterns submitted for comparison may be inadequate.

j. The gun or correct ammunition is not available.

2. Other factors to consider when interpreting results.

a. Signs of damage on the evidence from muzzle blast for contact, near contact, or close range shots.

b. The maximum range at which soot or smoke can be deposited.

c. The maximum range at which smokeless powder particles or lead particles can be deposited.

a. The conclusion should be reported as a range of distances - the closest possible distance the shot could have occurred to the farthest possible distance the shot could have occurred.

b. The range should include the most likely or most similar created target distance.

c. Stipulations or conditions should be noted in the conclusion such as:
   i. Given no intervening objects.
   ii. Given dissimilar ammunition.
   iii. Not knowing the positioning of the subjects.

d. The range of conclusions can be stated as below:
   i. Contact or near contact.
   ii. 1 inch to x inches, where x could be any number greater than 1.
   iii. Beyond x inches, where x is the maximum distance gunshot residues can be deposited.
   iv. Unable to determine range because no residues were found, the evidence was incomplete, or the information derived from the evidence was inconsistent.

e. When no gun or ammunition is submitted, the distance may be generally reported as contact, close, greater than a few feet or beyond a range at which deposits would be expected. This report should also state that a more precise determination could be made with the actual weapon and ammunition.

4. Example Conclusions. Below is a list of examples of possible conclusions.

a. Hole with gunshot residue pattern:

"When the gun was fired, the muzzle-to-shirt distance was between 6 and 18 inches assuming no loss of gunshot residue or intervening objects."
"When the gun was fired, the muzzle was in contact or nearly in contact with the sweatshirt."

"When the gun was fired, the muzzle-to-face distance was between 1 and 6 inches, assuming no loss of gunshot residue or intervening objects."

b. Hole with bullet wipe only or evidence with no detectable residues:

"When the gun was fired the muzzle to shirt distance was a distance greater than 4 feet. At 4 feet and beyond no residue was found on the test targets. This conclusion assumes no loss of gunshot residue or intervening objects."

G. Chemical Reagent Preparation.

1. Good laboratory practice dictates the use of appropriate precautions to prevent inhalation, ingestion, or skin contact with chemicals, whether in the preparation or use of reagents and test media. Ventilation, protective gloves, and hand washing are definitely recommended. Storage of prepared chemicals and test media should be such that no outside contamination or inter-contamination is possible. Storage containers should be kept sealed until the contents are needed.

2. Directions for reagent preparation are listed below. Weights and volumes may be scaled as necessary.

3. Modified Griess Reagents and treated paper.

   a. Treated paper for Modified Griess tests.
      i. Mix 0.5 g of sulfanilic acid in 100 ml of distilled water.
      ii. Mix 0.28 g of alpha-naphthol in 100 ml of methanol.
      iii. Combine equal volumes of the above solutions.
      iv. Pour the combined solution into a non-reactive tray. Briefly submerge sheets of glossy photographic ink jet paper into the solution.
      v. Set the sheets aside to dry on a clean, uncontaminated surface.
      vi. Place the remaining solution in a sealed storage container.
      vii. The paper can be stored in a sealed plastic bag.

   b. Nitrite test swabs.
      i. Mix 0.6 g of sodium nitrite in 100 ml of distilled water.
      ii. Soak the cotton-tipped ends of the swabs in the solution. About 100 swabs can be soaked in this solution.
      iii. After the swabs are dry they should be stored in a sealed container.

   c. 15% acetic acid solution.
      i. Mix 150 ml of glacial acetic acid with 850 ml of distilled water.
      ii. Store in a sealed container.

4. Sodium rhodizonate reagents.
a. Sodium rhodizonate solution.
   i. Prepare a saturated solution of sodium rhodizonate in distilled water.
   ii. The solution is saturated if slight sediment is seen on the bottom of the beaker after stirring with a stirring rod.
   iii. Make only enough solution for immediate use and do not store the solution. The solution degrades within one hour.

b. Tartrate buffer solution (pH 2.8).
   i. Dissolve 1.9 g of sodium bitartrate and 1.5 g of tartaric acid in 100 ml of distilled water.
   ii. Use a hot plate and magnetic stirrer to mix the solution in a reasonable period of time.
   iii. Store the solution in a sealed container. Contaminated containers, contaminated water, or containers left open may lead to a cloudy solution. While a cloudy solution do not interfere with the specificity or reliability of the test, they do may clog the reagent spraying equipment.

c. 5% hydrochloric acid solution.
   i. Combine 5 ml of concentrated hydrochloric acid with 95 ml of distilled water. Remember to gently pour the acid into the water to preclude potential spattering of undiluted acid.
   ii. Store the solution in a sealed bottle.

d. Potassium chloride with hydrochloric acid buffer and fixer solution.
   i. Dissolve 0.75 g of potassium chloride in 50 ml of distilled water.
   ii. Mix 5 ml of hydrochloric acid in 295 ml of distilled water. Remember to add the acid to the water.
   iii. Mix 25 ml of the potassium chloride solution and 67 ml of the hydrochloric acid solution to make a buffer solution with pH 1.0.
   iv. Store the solution in a sealed container.

5. Reagent References:

Nichols, R. Gunshot Proximity Testing: A Comprehensive Primer in the Background, Variables and Examination of Issues Regarding Muzzle-to-Target
H. Shotgun Pellet Patterns. Due to the dispersion of pellets in flight, the shot pattern can be used in distance determinations for shotguns. Other than the pellet pattern interpretation the rest of the examination is performed as above.

1. Examine the shot pattern in the garment, victim, wall, or other evidence items and determine:
   
a. The presence or absence of gunshot residue, sooting, shot pellets, shotshell components, and buffer material.
   
i. Components can be wads, shotcups,
   
ii. Buffer material is typically small pieces or plastic used to fill space between the pellets in the shot shell.
   
iii. Pellets may be made of lead, steel, bismuth, tungsten, and other materials.

b. Dimensions of the pattern.
   
i. The diameter of the circular pattern represented by the evidence if the shot was fired perpendicularly into a flat surface.
   
ii. Effects from intervening objects.

2. Fire test patterns at clean white paper at known distances to establish relationship between shot pattern diameter and muzzle-to-target distance.
   
a. A minimum of three patterns are needed for bracketing, one the size of the evidence pattern, one larger and one smaller.
   
   b. Use the shotgun and ammunition in question.

3. Use the test pattern diameter vs. muzzle to target distance to determine the distance the evidence pattern was fired. The error can be up to 30% unless multiple shots are fired at each distance to establish the variation in pattern diameter and density.

4. An optional test pattern could be fired at the established range with the target rotated to the angle of entry into the victim, wall, etc.

5. An old rule of thumb is that pellet patterns spread one inch for every one yard they travel when fired from a cylinder bore shotgun. Due to the range of chokes and the variety of new shotcups and loading techniques now available, this general rule can be misleading. Test firing is the best way to make a determination.

END OF DOCUMENT
I. POLICY  The Integrated Ballistic Identification System (IBISTRAX-HD3D) via the National Integrated Ballistic Information Network (NIBIN) allows the Comparative Evidence Unit to compare firearms evidence from many different cases.

A. Background

1. IBISTRAX-HD3D is a digitized computer database and acquisition platform for the firing pin impressions, breechface marks, and ejector marks found on cartridge cases. Acquired items are added to the database and every new acquisition is correlated against items previously entered into the database.

2. IBISTRAX-HD3D functions on NIBIN and allows the laboratory to search for potential associations within and outside of the county. If needed, a national search or out-of-state search can be performed. The images are correlated by servers at ATF (Bureau of Alcohol, Tobacco, Firearms and Explosives) and may be reviewed by the NIBIN National Correlation and Training Center (NNCTC) or the laboratory. The NNCTC is responsible for notifying the agency of any NIBIN Leads located by the NNCTC through notification emails.

B. Ballistic Imaging Requests

1. All firearms evidence submitted to the lab will be entered into IBISTRAX-HD3D if suitable.
   a. Examples of non-suitable firearms include: revolvers, derringers, shotguns, and rifles other than .223 Remington (5.56mm, or compatible) and 7.62x39mm caliber. Exceptions may be made by the unit supervisor, a manager, or the Chief.
   b. IBISTRAX-HD3D does not support bullet entry.

2. The examiner will determine if the evidence can and should be entered into IBISTRAX-HD3D based on several factors:
   a. Safety and functioning of the firearm.
   b. Extent of damage or corrosion to cartridge cases. Undamaged cartridge cases are preferred for entry.
   c. Rarity or uniqueness of the firearm or ammunition.

3. All firearms submitted for Ballistic Imaging will follow policy CE.03.
4. Cartridge cases will be sorted into groups based on an evaluation of class characteristics.
   a. The stereoscope is typically used (with direct and oblique light) to sort fired components. A comparison microscope with oblique light should be used when examining multiple groups of similarly-marked items based on class characteristics (e.g. eight Remington 40 S&W cartridge cases and nine Winchester 40 S&W cartridge cases) or when the markings are not straightforward.
      i. If needed, another analyst may be consulted to confirm the grouping based on class characteristics.
   b. The class characteristics evaluated will be recorded with photographs, notes, and/or worksheets to document the characteristics used for sorting.

5. An abbreviated safety inspection will be performed on submitted firearms. Trigger pull measurements do not need to be taken.
   a. At least two test fires will be collected and treated as evidence. These test fires will generally be maintained in the laboratory to expedite follow-up identification requests.

C. Operation

1. IBISTRAX-HD3D operations
   a. Refer to the latest edition (INSCE.05) of the BRASSTRAX and MATCHPOINT Training Guides from Ultra Electronics / Forensic Technology for specific information on operating the IBISTRAX-HD3D system.

D. Data Entry -- Clarification of standard NIBIN procedures specific to the Contra Costa County Sheriff Forensic Services Division

1. Case identification codes: "CCC" followed by the laboratory case number including request suffix (if applicable). The Contra Costa County Crime Laboratory has been assigned "CCC" as its database location code.
   a. For example, laboratory case # 07-123-1 would be entered as "CCC07-00123-1".

2. Exhibit identification codes: "EX" followed by a dash and the item number.
   a. For example, a fired cartridge case, item #12 would be entered as "EX-12".

3. Test-fire identification codes: "TF" followed by the test fire number followed by a / and the agency or lab item number, or vice versa.
   a. For example, a test-fired cartridge case #1 from a firearm (item #3) would be entered as "TF1/3" or EX-3/TF-1.

4. All other information is entered according to the latest acquisition protocol.
   a. INSCE.04 is the latest guide for acquisition.
   b. The key orientation guideline is to orient the firing pin drag mark at 3 o'clock (if present).
i. If no firing pin drag mark is present, orient the ejector mark in the northern hemisphere. If there is no ejector mark, orient the extractor mark in the southern hemisphere.

c. The next orientation guidelines are to orient parallel breechface marks horizontally, arched breechface marks with the peaks upwards, and cross-hatched lines to intersect diagonally.

5. Correlation reviews:
   a. The NNCTC will typically perform NIBIN correlations and will notify the laboratory and the agency of any NIBIN Leads. If the NNCTC generates a NIBIN Lead, the laboratory is not required to review it.
   b. If the laboratory performs the correlation, the examiner will compare images from the correlation list to the acquired item. If images with similar marks are found such that the primary examiner feels a NIBIN Lead is justified, a criminalist trained in identifications will review the images and document their agreement with the primary examiner's conclusion on the printout showing the two items.
      i. The extent of the correlation review by an examiner is the top 30 candidates using rank sort. The candidate list for any correlation done by the laboratory will be included in the case notes.
   c. The submitting agency will decide if an identification is needed to confirm the Lead. The lab may request the identification be performed under exigent circumstances.
   d. Upon confirmation by traditional optical microscopy, the Lead will be marked as a confirmed match in the database.

6. The evidence is returned to the submitting agency as described in Division Policy.

E. IBISTRAX-HD3D Training and Competency

1. IBISTRAX-HD3D training may be provided by Ultra Electronics Forensic Technology, Alcohol, Tobacco and Firearms (ATF), or other qualified personnel.
   a. The trainer provides hands-on practical training with a sufficient number of samples to enter into IBISTRAX-HD3D. The training they provide is required for all users of the IBISTRAX-HD3D system. After successful completion of the training, the user is provided a certificate to document the successful completion of training.
   b. The laboratory will use this training and these provided tests as the competency test (test of sufficient unknowns and test of knowledge) for IBISTRAX-HD3D. The training and tests will be documented in LIMS.

F. Reports

1. A Ballistic Imaging report will be produced for every case submitted for entry, whether as a stand-alone report or as part of another report. A separate Ballistic Lead notification will document any NIBIN Leads located by the NNCTC. If the laboratory performs the correlation, the results may be included in a single report or with a separate Ballistic Lead notification.
a. The NNCTC NIBIN Lead documentation will be incorporated as part of the notes for Ballistic Lead notifications.

b. The submitting agency will need to submit an identification request if they want the NIBIN Lead confirmed.

2. The report will include the extent of the database searched (e.g. Zone 4), the frequency of searches, and the duration of the search.

G. Individual Characteristic Database (ICD): IBISTRAX-HD3D is an ICD and images in the database are treated as reference material.

1. All images are uniquely identified, based on case number, item number, and test-fire number if applicable.

2. The test-fired cartridge cases imaged by IBISTRAX-HD3D are treated as evidence.

3. All images are protected from loss, cross transfer, contamination, and deleterious changes. Periodic backups of the hard drives storing the database and the procedures for handling and packaging of the test fires assist in this protection.

4. Access to the images is controlled and only those individuals using the IBISTRAX-HD3D will have authorization to access them. IBISTRAX-HD3D operates on a secure network that is managed by ATF. It requires a password to access.

H. Removal of entry

1. Upon specific request from an agency, the laboratory may remove an entry from the database. The laboratory will issue a report that the entry was removed.

END OF DOCUMENT
I. POLICY  Tools and items with toolmarks may be submitted to the laboratory to determine if a specific tool was responsible for creating the toolmarks.

A. Toolmark Comparisons.

1. General Information.
   a. Evidence will usually consist of an object with a toolmark or a cast of a toolmark and a suspected tool. All trace evidence collection and latent fingerprint processing should be completed prior to toolmark examination.
   b. Note: Never place a tool in contact with a toolmark as this may permanently change the tool and toolmark.
   c. Firearms comparisons are a subset of toolmark comparisons and the overall procedures are similar.
   d. Limitations.
      i. Suspected tools should be obtained as soon as possible after the evidence toolmark was made. The working surfaces of the tools change through use or alteration and thus the toolmarks made with that tool will change.
      ii. Tools and toolmarks can be damaged by rust or corrosion. Therefore, evidence should be collected as soon as possible and stored properly to minimize rust or corrosion.

2. Initial documentation. The tool, if submitted, along with the questioned toolmarks shall be described in the notes or worksheets prior to comparison.
   a. This documentation includes the evaluation of the unknown item(s) to identify characteristics suitable for comparison prior to comparison to the known item.
   b. This examination may include an assessment of class characteristics, potential subclass influence, and/or potential for identification.
      i. This documentation may be accomplished with notes, sketches, photographs, or a combination of these methods.
1. The following are examples of this process: noting a well-
striated, linear toolmark approximately 1/4-inch wide with well-
deﬁned margins; two sets of parallel, tooth-like impressions with
a cross-hatched texture on opposing sides of the same evidence
item; a cut lock shackle with a cut area having a tented proﬁle,
with one exposed surface having a uniformly striated appearance
and the other having a partially striated and partially irregular
appearance.

ii. Nothing in this section prevents an analyst from later examining areas
not evaluated at the initial documentation stage, should it be necessary.

3. Comparison procedure.

a. Document the condition of the evidence as received. Record the presence or
absence of trace evidence using notes, sketches and/or photographs. Collect
and package any trace evidence that is present either on the evidence
toolmarks or the submitted tools.

b. Mark the evidence or proximal container with permanent identiﬁcation. Do
not deface evidence and do not alter the toolmarks or the working surfaces of
the tools.

c. Examine the evidence toolmarks and determine:
   i. If there is sufﬁcient individual detail present for comparison and
      possible identiﬁcation purposes.
   ii. The class characteristics of tools that may have been used including:
      1. Single bladed, opposed jaws, impact, etc.
      2. Length and width of blades
      3. Number and shape of teeth
   iii. Are the toolmarks the result of compression, motion producing
      striations, or both?
   iv. Document details of the toolmark using notes, sketches and/or
      photographs.

d. Examine the submitted tool and determine the following (Record your
   ﬁndings using notes, sketches and/or photographs):
   i. The class characteristics of the tool.
   ii. The presence or absence of subclass characteristics.
   iii. If the tool produces unique toolmarks.
   iv. If there is evidence as to how the tool was used.
   v. If the tool has any damage to the working edges.
   vi. If there is any evidence of which surface on the tool was the working
       surface.
   vii. If there are physical limitations that require the tools to be used in a
certain manner, thus eliminating some tools or restricting which part of
the tool could make the marks.

viii. How the tool was used can help with reconstruction. For example, from what side was the fence cut?

ix. How was the tool manufactured? Manufacturing processes determine possibilities of uniqueness. Cast tools made from the same mold may make similar toolmarks unless the working surface has enough damage to make it unique. Hand finishing of the working surface may make tools unique. Grinding, filing, sanding of the working surface may make tools unique.

e. Make test marks.

i. If the class characteristics of the tool and the toolmark agree, make testmarks in a soft material like lead.

ii. The goal is to prepare a representative testmark without changing the features of the tool. The test material may eventually need to be as hard as the questioned material in order to produce a representative toolmark. In these cases, the test materials of progressive hardness should be tried until satisfactory test marks are obtained. Retain all test marks made with hard material since testing with this material may alter the tool working surface. Keep a record of the sequence of the test marks made (T-1, T-2, etc) and document how each test series was prepared. Place adequate identification marks on all test marks.

iii. Forensic Sil or Mikrosil casts of the toolmark and testmarks may be used for comparison when necessary. Conditions that could lead to this are:

1. The object with the working surface or toolmark is too big to fit on the stage of the microscope or is too big to collect.

2. The working surface or toolmark is in a place that cannot be examined easily.

3. The original marks are on a surface that is too reflective to resolve good detail when viewed through the microscope with direct lighting.

   1. Mark the casts to match the series of test marks they replicate (T-1, T-2, etc.) and place adequate identification marks on each cast.

iv. Use precautions when creating test marks. Tools can be heavy and have sharp edges. Follow safety procedures when producing test marks.

f. Compare the toolmarks.

i. Compare the test marks to each other to determine if the toolmarks are reproducible. Note which part of the tool was the working surface used, the orientation of the tool to the working surface, and the direction of force used on the tool.

ii. Compare the test toolmarks with the evidence marks.
iii. Consider making a sketch of the orientation of the questioned and test marks, or casts made of them, relative to the stages of the comparison microscope. This helps keep track of which comparisons have been made.

iv. Take low and high power photographs of any matching detail.

v. Count consecutive matching striae (CMS) runs, if applicable, and record these in the notes.

vi. Record whether the toolmarks appear to be two or three-dimensional as it pertains to the quantitative consecutive matching striae (QCMS) criteria.

   a. Conclusions should follow the same convention already discussed in Section CE.04 Case Documentation and Conclusions.

END OF DOCUMENT
I. **POLICY** Questioned footwear and tire impressions can be compared to known shoes and tires to determine if they are associated.

A. **Introduction**
   
   1. Footwear and tires act like tools when they leave impressions in or on other materials. Because the treaded surfaces of shoes or tires are subject to wear and damage, they may contain unique features that may be observed in impressions on materials that they come into contact with. This is the basis for footwear and tire print comparisons.

B. **Materials and Equipment (unless specified in this document, refer to manufacturer's instructions or CS.10 for procedures for use)**
   
   1. Assorted powders including, but not limited to, fingerprint powders.
   2. Media for making test impressions and overlays for comparison, including adhesive lifters (e.g., Handiprint paper) and transparency sheets (including roller transport clean-up film)
   3. Photocopier or computer scanner
   4. Camera
   5. Measuring equipment (drafting dividers, rulers)
   6. Simple magnifying lens
   7. Adobe Photoshop
   8. Reference data (*Tread Design Guide*, online sources)

C. **Footwear and Tire Impression or Print Examination Procedure**
   
   1. **Evaluation**
      
      a. Evidence shall be documented and described in the case notes.
      
      b. If photographs are taken by the examiner for comparison purposes, they should include a scale and pertinent case information.
      
      c. When photographs of footwear or tire tread evidence are submitted, they should be evaluated to determine the limitations of any comparison. Generally, they should be enlarged to 1:1 scale if suitable for comparison.
d. The nature of the surface material upon which the print or impression was produced should be determined, if possible.

e. When appropriate, trace evidence from footwear or tires should be documented, preserved, and collected for analysis.

2. Digital Enhancement

a. Adobe Photoshop

i. Adobe Photoshop is a software program used to resize or superimpose images of footwear or tire impressions for comparison, to annotate digital images, and to prepare images for demonstrative purposes (e.g., examination notes, court displays). Digital image enhancements include any process that changes the brightness, contrast, or color of any area of an image. The term “digital enhancement” does not include changes to images that do not alter the content or do not increase visibility.

1. The following examples are common uses of Photoshop that require general documentation.

   1. Cropping
   2. Annotations

2. When image enhancements are made in Photoshop, screenshots of the final settings of each filter will be recorded in the technical record. The technical record should include all settings so that a different examiner with the same level of training can reproduce the enhancements. Enhancements will be made to a working copy only. The following are examples of enhancements that can be done in Photoshop that need to be documented in the technical record:

   1. Contrast/brightness adjustments
   2. Rotating
   3. Inverting or changing the color appearance of an image
   4. Diminishing/eliminating background colors or patterns to improve visualization of an impression
   5. Re-scaling images to natural size (1:1)

      1. There are a few techniques for using Photoshop to re-scale an image to 1:1 by using a scale depicted in the image for reference. Any such technique may be used, as long as an acceptable resolution of potential individual characteristics is retained and the depicted scale in the final image is checked with a comparable real-world scale prior to use for comparison.

      3. The use of Photoshop to perform any enhancements described above requires identifying the use of Photoshop as a method in the report.
1. Example language: "I enhanced the brightness and contrast of the submitted evidence images using Adobe Photoshop's Curves and Smart Sharpen filters and scaled them to natural size (1:1 scale) using Photoshop's Scale tool."

4. Planned maintenance and intermediate checks are not necessary to ensure the performance of this equipment.

3. Comparison
   a. Prior to comparison of the unknown to the known, the unknown shall be evaluated to identify characteristics suitable for comparison.
      i. This evaluation may be accomplished with notes, sketches, photographs, or a combination of these methods.
         1. The evaluation process need only assess the quality of the questioned print(s) or impression(s) and potential areas of use for comparison; every discernible class and individual characteristic present in the unknown does not need to be individually inventoried and evaluated.
         2. For clear and well-defined questioned print(s) or impression(s), the evaluation process may be documented with a simple statement in the notes regarding the overall quality and detail present.
         3. Nothing in this section prevents an analyst from later examining areas not evaluated at the initial evaluation and documentation stage or even changing their initial analysis, should it be necessary, as long as any such changes are documented.
   b. Class characteristics of the evidence print or impression are compared to the known shoe or tire.
      i. If class characteristics are in agreement and the evidence print or impression has sufficient detail, then individual characteristics can be evaluated and compared.
      ii. When making initial examinations, the examiner should be aware that additional wear of the exemplar shoe or tire may have occurred since the evidence was made. The addition wear may result in alterations of the class and individual characteristics of that shoe or tire.
      iii. Test prints and impressions are used for comparison to evidence prints or impressions.
   c. Individual characteristics - examiners should use their training and knowledge of manufacturing methods toward evaluating marks for their individuality.
   d. A number of useful techniques are available for the preparation of test prints, including:
      i. The sole of a shoe is coated with latent fingerprint powder (using a fingerprint brush) or inked (using a roller). A test print is then produced by pressing the sole onto paper or a transparent sheet. If
needed, clear acrylic lacquer spray may be used to preserve test prints. Roller transport film and adhesive Handiprint paper may also be used.

1. Roller Transport Clean-Up Film/Handiprint Technique for Making Test Footwear Impressions

1. Roller transport film is a clear photographic film used to clean photographic equipment. Although supplies of this material are now becoming scarce due to the demise of the photographic film industry, it offers the advantage of producing a very clear transparency (with no cover sheet) and an excellent recording of fine detail in test impressions.

1. Lightly dust the sole of the test shoe with fingerprint powder.

2. Place a sheet of butcher paper on floor, followed by a towel and another sheet of paper.

3. Get a sheet of roller transport film moderately wet with water using the sponge side of a window squeegee.

4. Wipe off the excess water with the rubber side of the squeegee.

5. Place the film (wet side up) on the top sheet of paper on the floor.

6. Wearing the shoe, step onto the film to make a test print.

1. Both static and rolled prints may need to be made.

7. Immediately make a second test print onto a sheet of white adhesive Handiprint paper.

1. Use a rubber fingerprint roller to press the Handiprint paper onto the entire surface of the shoe shoe before removing.

2. After removing Handiprint paper from shoe, apply a clear cover sheet over the test impression. Use the fingerprint roller as the cover sheet is applied to minimize the entrapment of air bubbles between the two sheets.

8. Label the test impressions with lab number, date collected, analyst's initials, which shoe (left or right), and how impressions were made (e.g., static or rolled).

9. The Handiprint test print will usually be darker than the one made with roller transport film.
ii. Tire test prints should be made with the tires on the vehicle whenever possible. Roll the entire circumference of the inked or powdered tire over a suitable media (e.g. paper, transparent sheets, foam board, or cardboard) on a smooth, hard surface.

iii. If the evidence print is in the form of an electrostatic dust print lift or recovered using adhesive lifters, the examiner may make test prints using the electrostatic print lifter or adhesive lifters.

iv. It is helpful to make multiple sets of test prints with varying densities of pigment (light and dark) for comparison with the questioned print(s).

e. If a transparency or photograph is used, the examiner should compare it to the original item to ensure accuracy. Scales should be included whenever possible.

f. Test impressions may be produced by making an impression of the evidence footwear or tire into a similar medium as the questioned print. Casts of the test impressions may then be prepared.

g. Both test and evidence prints and impressions should be photographed using appropriate lighting. A scale and appropriate case information should be included in the photograph.

**D. Interpretation**

1. Intercompare test prints and impressions for reproducibility of class and individual characteristics prior to comparing evidence prints and impressions.

2. Document significant similarities and differences using appropriate notes, sketches, and photographs.

3. Transparent overlays are often beneficial when comparing test and evidence impressions. Due to differences in surfaces and preparation, the alignment of all features may not be possible. Differences need to be identified and explained before reaching a conclusion.

4. Evaluate the significance of similarities or differences in the class and individual characteristics between the evidence and test prints or impressions.

5. Distinguish between class and individual characteristics before rendering any conclusions regarding an identification, inclusion, or elimination. Some class characteristics to be considered are: tread pattern, wear, size of the pattern elements, and overall size. Some individual characteristics to be considered include the location, orientation, shape, and apparent randomness of any post-manufacture defects.

   a. The most important aspects to the evaluation of individual characteristics are the clarity and uniqueness of the mark.

6. Conclusions.

   a. These conclusions do not have exact requirements. The examiner must use his or her training and experience to determine the significance of agreement or disagreement that is present between the evidence print and the suspect footwear. The basis for the final conclusion will be documented in the test record and the report.
b. The appropriate qualification to the significance of the association will be included in the report.

c. The Scientific Working Group for Shoeprint and Tire Tread Evidence (SWGTRREAD) range of conclusions may be used:

i. Lacks sufficient detail

1. No comparison was conducted: the examiner determined there were no discernible questioned footwear/tire impressions or features present. This opinion applies when there is insufficient detail to conduct any comparison.

   1. In the opinion of the examiner, an impression was either not present or the impression lacked sufficient detail for any comparison.

2. A comparison was conducted: the examiner determined that there was insufficient detail in the questioned impression for a meaningful conclusion. This opinion only applies to the known footwear or tire that was examined and does not necessarily preclude future examinations with other known footwear or tires.

   1. In the opinion of the examiner, the impression lacked sufficient detail for a meaningful conclusion regarding the particular known footwear outsole or tire tread.

ii. Exclusion

i. This is the highest degree of non-association expressed in footwear and tire impression examinations. Sufficient differences were noted in the comparison of class and/or randomly acquired characteristics between the questioned impression and the known footwear or tire.

   i. In the opinion of the examiner, the particular known footwear or tire was not the source of, and did not make, the impression.

iii. Indications of non-association

i. The questioned impression exhibits dissimilarities when compared to the known footwear or tire; however, the details or features were not sufficiently clear to permit an exclusion.

   i. In the opinion of the examiner, dissimilarities between the questioned impression and the known footwear or tire indicated non-association; however, the details or features were not sufficient to permit an exclusion.

iv. Limited association of class characteristics

i. Some similar class characteristics were present; however, there were significant limiting factors in the questioned impression that did not permit a stronger association between the questioned impression and the known footwear or tire. These factors may include but were not limited to: insufficient detail, lack of scale,
improper position of scale, improper photographic techniques, distortion or significant lengths of time between the date of the occurrence and when the footwear or tires were recovered that could account for a different degree of general wear. No confirmable differences were observed that could exclude the footwear or tire.

i. In the opinion of the examiner, factors (such as those listed above) have limited the conclusion to a general association of some class characteristics. Other footwear or tires with the same class characteristics observed in the impression are included in the population of possible sources.

v. Association of class characteristics

i. The class characteristics of both design and physical size must correspond between the questioned impression and the known footwear or tire. Correspondence of general wear may also be present.

i. In the opinion of the examiner, the known footwear or tire is a possible source of the questioned impression and therefore could have produced the impression. Other footwear or tires with the same class characteristics observed in the impression are included in the population of possible sources.

vi. High degree of association

i. The questioned impression and known footwear or tire must correspond in the class characteristics of design, physical size, and general wear. For this degree of association there must also exist: (1) wear that, by virtue of its specific location, degree and orientation make it unusual and/or (2) one or more randomly acquired characteristics.

i. In the opinion of the examiner, the characteristics observed exhibit strong associations between the questioned impression and known footwear or tire; however, the quality and/or quantity were insufficient for an identification. Other footwear or tires with the same class characteristics observed in the impression are included in the population of possible sources only if they display the same wear and/or randomly acquired characteristics observed in the questioned impression.

vii. Identification

i. This is the highest degree of association expressed by a footwear and tire impression examiner. The questioned impression and the known footwear or tire share agreement of class and randomly acquired characteristics of sufficient quality and quantity.

ii. In the opinion of the examiner, the particular known footwear or tire was the source of, and made, the questioned impression.
Another item of footwear or tire being the source of the impression is considered a practical impossibility

7. Verification of Conclusions
   a. All conclusions with comparison conclusions shall be verified by another qualified examiner except for eliminations based on class characteristics. The verifier will initial and date the test record to document their agreement with the original examiner's conclusion.
   b. Verification should be done as contemporaneously as possible to the original examiner performing their examination.
   c. The verifier should not be told of the original examiner's conclusion. The original examiner should only provide the verifier with contextual information (e.g., identity of items being compared).
   d. The verifier must reach the same conclusion as the examiner. Any differences in opinion should try to be resolved by the examiner and verifier. The Comparative Evidence Supervisor can arbitrate situations where agreement cannot be reached. The supervisor can decide in favor of either conclusion or send the evidence to another laboratory for arbitration if needed.

E. Class Characteristic Database Searches (Make/Model Determination)
   1. Footwear
      a. The tread designs of many shoes are proprietary to a particular footwear manufacturer/marketer and the resultant footwear impression may be readily recognizable as such, either based on the examiner's personal knowledge or trademarks that have been incorporated into the tread design itself. In some cases, the manufacturer/marketer may be easily determined, but the specific style of shoe is to be determined. Although some subscription-based forensic databases for footwear tread designs are available (see below), there are also numerous other resources that may be used to search for the manufacturer/marketer associated with a particular footwear impression from a crime scene, including:
         i. Internet resources (e.g., Google image search, collector websites)
            1. Some footwear brands and styles (e.g. Nike Air Jordan) are highly sought after by collectors, and therefore a great amount of information about these shoes (including photographs of the tread design, release date, colorways, etc.) can often be found on various websites.
         ii. Shoe stores
            1. Sometimes useful information can be gained by visiting local shoe stores and directly observing the tread patterns associated with their current stock of shoes on display.
         iii. Direct contact with manufacturer/marketer
            1. Some manufacturers, such as Nike, employ a representative to act as a liaison for law enforcement agencies due to frequent problems with their products being counterfeited. These representatives can provide a wealth of information regarding a
questioned shoe impression, including production and distribution details.

iv. Electronic databases (e.g., Foster + Freeman's SICAR) may also be used to conduct a search, as available.

v. The resource used must be clearly documented in the notes.

b. Any potential candidates reported on the basis of a preliminary search of reference guides or databases (without confirmation by the manufacturer) must be reported with a statement which indicates that the results are not all-inclusive of every shoe manufactured and any suspected shoe should be submitted for examination.

2. Tires

a. Tread Design Guide

i. The primary resource for conducting searches of tire tread designs is the *Tread Design Guide*, published by Tire Guides, Inc. These guides are published annually and consist of a compilation of thousands of photographs of tread designs subdivided into passenger, light truck, medium and large truck, off-road, agricultural, ATV and motorcycle, and retread sections.

1. The photographs of the tires in the *Tread Design Guide* are provided to the publisher by the various manufacturers each year and represent about 95% to 98% of the tires available on the market.

2. Approximately 400 to 500 new tire designs are placed into the *Tread Design Guide* each year.

3. Photographs of tread designs featured in prior years that are no longer being manufactured are removed from the *Tread Design Guide* in subsequent years.

ii. Using the printed editions of the *Tread Design Guide* to search for a tire impression recovered from a crime scene involves visually searching, page-by-page, every photograph contained in each annual edition until a likely candidate is found.

1. Since the *Tread Design Guide* is published annually, when searching for a tread design a decision must be made regarding which year's guide will be used to begin the search.

   1. Based on a crime scene impression alone, the examiner will not likely know if the vehicle that made the impression was new or old and thus would not know if it was equipped with original equipment tires or replacement tires.

   2. Some tire designs are made for many years and thus appear over and over again in each year's edition, while other tires are only made for one year and only appear in that single year's edition.

   3. The choice of what year to begin the search with should be well reasoned based on the circumstances of the case.
For example, if the crime occurred in 2017, then the search could begin with the 2017 guide or earlier years. If the search is being conducted relative to a cold case that occurred several years prior, then only guides from the year of the crime and earlier would need to be searched.

4. Searching for a tire design through the *Tread Design Guide* is a procedure that often requires searching several years' editions before finally locating an appropriate candidate.

2. Since the *Tread Design Guide* includes more than one category of vehicle (e.g., passenger, light truck, medium truck, etc.), a decision must be made for which category to search first, even though it is not usually known what type of vehicle made the scene impression.

1. Most vehicles involved in a crime are either passenger vehicles or light trucks.

2. The size of the impression, any available track measurements, and even possibly witness information, may provide clues as to which category should be searched first.

3. From the crime scene impression, select a primary feature, such as the number of circumferential grooves, as well as a couple of secondary features that appear to be the most reliable for the search.

1. When using a photographed tire impression from a crime scene to conduct the search, it is helpful to reverse the image so the design features will appear in the same orientation as the tire photographs in the *Tread Design Guide*.

2. A secondary feature might be something as obvious and simple as an angled transverse groove or the features of the center rib.

3. As the section is searched, tires that do not contain the primary feature can be skimmed over; when tires containing the primary feature are found, the secondary features can be used to further narrow down the choice of potential candidates.

4. As tires wear down, their design features change. Be aware of this possibility and take it into consideration when selecting the primary and secondary features for the search. Try to select features that are less likely to change as the tire wears (i.e., larger design elements of the tread pattern). Try to avoid smaller features, such as sipes and transverse grooves, which may have an altered appearance from when the tire was new.

5. If a tire is found in the *Tread Design Guide* that is almost an exact match but contains minor differences, contacting
the company who makes the similar tire may help determine if the tire is theirs. If it is not, the company representative may be aware of whose design it is.

b. Tread Assistant

i. *Tread Assistant* is a searchable electronic database (published on a CD-ROM) of the *Tread Design Guides* for the years 1990-2010. Although it is no longer updated or supported by Tire Guides, Inc., *Tread Assistant* is still a useful search tool for tread design data for the years it covers and can be used to supplement searches conducted for other years using the printed guides.

ii. The database provides ways to search for specific tire designs based on the category of tire (e.g., passenger, light truck, etc.), the number of circumferential grooves, (0 to 8), and other criteria.

iii. Since the database contains several years worth of designs, all of these years are being searched simultaneously, saving considerable effort over searching the printed guides for these years.

c. OEM Tire Size Guide

i. The *OEM [Original Equipment Manufacturer] Tire Size Guide*, published by Tire Guides, Inc., was first published in 1996 and provides information regarding tire brands and sizes used as original equipment on new vehicles.

1. Each year's edition covers vehicles for the present year and approximately 10 years prior as well.

2. This resource also provides an index of tire sizes and what vehicles used those sizes.

3. The *OEM Guide* also includes a section that lists vehicles by model year and then lists the brands and lines of tires as well as the sizes that were used on each new car or truck.

4. Under certain circumstances, it may be possible to cross-reference the information obtained from the *Tread Design Guide* with the *OEM Guide* in order to determine what specific make and model of vehicle likely made a tire impression from a crime scene.

d. The *Tire Design Guide, Tread Assistant, and OEM Tire Size Guide* should always be considered as guides only, thus any information should be confirmed with the respective tire company or vehicle's manufacturer, depending on case circumstances. The resource used must be clearly documented in the notes.

i. Any potential candidates reported on the basis of a preliminary search of reference guides or databases (without confirmation by the manufacturer) must be reported with a statement which indicates that the results are not all-inclusive of every tire manufactured and any suspected tire should be submitted for examination.

END OF DOCUMENT
I. Policy: The Comparative Evidence Unit has assessed the estimated uncertainty for the firearm length standards, trigger pull determinations, and distance determinations.

A. The uncertainty for reported overall and barrel length measurements is indicated in the Uncertainty Budget for Reported Overall Firearm Lengths (UM.06), the Uncertainty Budget for Reported Barrel Lengths (UM.07), the Uncertainty Budget for Trigger Pulls (UM.08), and the Uncertainty Budget for Distance Determinations (UM.09).

B. The Comparative Evidence Unit has attempted to identify all components of uncertainty associated with measuring overall firearm length, barrel length, trigger pulls, and distance determinations to make a reasonable estimation of uncertainty.

1. The overall length or barrel length needs to be included in the test report when the overall length or barrel length is requested or when the analyst chooses to report it. The trigger pull is only required to be included in the test report if requested by the submitting agency. Distance determination uncertainty is required to be in the test report whenever test panels are created.

2. All reported measurements will include the uncertainty and coverage probability.

3. Fractions used in reported results will be expressed with the lowest common denominator. The calculated uncertainty for the steel ruler is ± 0.155 inches; the reported value will be rounded up and reported as ± 1/4 inch. The calculated uncertainty for the Hott Rod is ± 0.103 inches; the reported value will be rounded up and reported as ± 1/8 inch. (See CE.35 for the uncertainty calculations.) The calculated uncertainty for trigger pulls is ± 0.490 pounds; the reported value will be rounded up and reported as ± 1/2 pound. The calculated uncertainty for Leica Disto is ± 0.121 inches; the reported value will be rounded up and reported as ± 1/8 inch. For example:

   a. "The rifle was determined to have an overall length of 25 3/16 inches ± 1/4 inch with coverage probability of approximately 95%.”

   b. "The rifle was determined to have a barrel length of 15 7/16 inches ± 1/8 inch with coverage probability of approximately 95%.”

   c. "The single-action trigger pull was determined to be 4 1/2 pounds ± 1/2 pound with coverage probability of approximately 95%.”

   d. "All test fire distances have an estimation of uncertainty of ± 1/8 inch with a coverage probability of approximately 95%.”

   e. "Test panels were created at distances of [list of values] ± 1/8 inch with a coverage probability of approximately 95%.”

4. The legal thresholds are defined in the Penal Code as:
a. Rifle: 16 inch barrel and 26 inch overall length,
b. Shotgun: 18 inch barrel and 26 inch overall length,
c. Assault weapon: 30 inch overall length.

5. When overall and barrel length measurements are within the uncertainty of measurement of the legal threshold, a conclusion regarding the item's legality will not be reported.

C. Measurement uncertainty is defined as:

1. The variability attributed to a quantitative measurement result based on the information known about the measurement method.

2. The technical use of the word "uncertainty" indicates a level of confidence in the result or the test being performed or the measurement.

3. The uncertainty of a measured value is an interval around that value such that any repetition of the measurement will produce a new result that lies within this interval. This uncertainty interval is assigned by the experimenter following established principles of uncertainty estimation.

4. The laboratory has attempted to take into account the extent to which the following factors contribute to the accuracy, reliability, and total uncertainty of length measurements in the uncertainty budget.
   a. Human Factors
   b. Accommodation and Environmental Conditions
   c. Test and Calibration Methods and Validation
   d. Equipment
   e. Handling of Test and Calibration Items

5. Sampling is not applicable to examinations performed by the Comparative Evidence Unit.

D. The Unit evaluated the uncertainty associated with weighing bullets on digital scales as one observation in the qualitative determination of caliber. The uncertainty of measurement of this process was determined to not significantly contribute to the determined value.

II. Estimated Measurement Uncertainty Budgets

A. Elements of Traceability

1. An unbroken chain of comparisons: An unbroken chain of comparisons that is traceable from the measurement result in the laboratory back to national (NIST) or international (SI) primary standards.
   a. See "Traceability of Firearm Length Standards" flow chart at the bottom of this document for how these standards are traced back to NIST.

2. Measurement uncertainty: The measurement uncertainty for each step of the traceability chain must be calculated and reported so that an overall uncertainty may be estimated.
   a. See the uncertainty budgets (UM.06, UM.07, UM.08, and UM.09), which take into account all estimated uncertainty at each step along the traceability chains.
   b. Standard scientific rounding is used in the calculation of measurement uncertainty. The CE unit may further round for clarity in the report as described above.
3. **Documentation:** Each step of the chain must be performed according to documented procedures, and the results must be documented.
   
a. See Laboratory records for documentation. The reference for each element or line item in the uncertainty budget has been given.

4. **Competence:** The laboratory performing steps in the chain must supply evidence of technical competence (e.g., ISO/IEC 17025 accreditation).
   
a. Rice Lake is the Laboratory-approved external vendor for calibration, is ISO/IEC 17025 accredited by A2LA.

5. **Reference to SI units:** Where possible, the chain of comparisons must end at the primary standards for the realization of the SI units.
   
a. Rice Lake is the Laboratory-approved external vendor for calibration, has established traceability to the appropriate SI units.

6. **Re-calibration at appropriate intervals:** Calibration must be repeated at appropriate intervals depending on the uncertainty required.
   
a. The CE Unit has established annual calibration checks. (See CE.06.)
   
b. The uncertainty budgets will be evaluated after annual calibrations to verify that the uncertainty associated with the equipment has not significantly changed.

7. **Measurement Assurance:** Validates and verifies elements 1 through 6 above
   
a. The Laboratory will periodically check, before each use, the physical condition of the length standards for any damage that may affect measurement reliability. If any negative condition exists, the unit supervisor must be notified.
   
b. The measurement standards will be stored in their factory containers when not being used. This includes when transporting the standards for calibration.
   
c. The Laboratory will maintain the calibrations records for the standards.
   
d. If new equipment or staff are added then the Estimated Uncertainty will be recalculated to reflect the additions.

B. **NIST 8-step approach to estimating uncertainty**

1. **Specify the measurement process**

   **Overall Firearm Length:** The distance between the planes perpendicular to the axis of the bore of the two most distal points at either end of a firearm, measured parallel to the axis of the bore. This measurement includes any permanently attached accessories and is measured using a steel ruler with the firearm lying on a horizontal surface. See *Uncertainty of Measurement: Overall Firearm Length & Barrel Length* policy ([CE.35](#)) for the procedure.

   **Firearm Barrel Length:** The length of the barrel (to include the length of the chamber on pistols, rifles, and shotguns) is measured using a Hott Rod™ inserted in the bore. See *Uncertainty of Measurement: Overall Firearm Length & Barrel Length* policy ([CE.35](#)) for the procedure.

   **Trigger Pull:** The amount of force which must be applied to the trigger of a firearm to cause sear release. See *Function Testing and Test Firing* policy ([CE.09](#)) for the procedure.
Distance Determination: The distance between the muzzle and the test target. See Distance Determination policy (CE.14) for the procedure.

2. Identify and characterize the uncertainty sources
   a. The Laboratory used a "fishbone" diagram (see below) and brainstorming techniques to identify possible sources of error.

3. Quantify uncertainty measurements
   a. The Laboratory uses "inches" and "pounds" for the estimated measurement uncertainty SI units.

4. Convert factors to standard uncertainties
   a. The Laboratory converted factors to standard uncertainties, one standard deviation equivalent, based on the distribution (normal or rectangular distribution) and multiplier of the "source of " data.

5. Calculate combined standard uncertainties
   a. The Laboratory uses the "root sum square" equation.

6. Expand the uncertainty by "k"
   a. The coverage factor is the multiplier used to establish the confidence level reported.
   b. The Laboratory uses a coverage factor of k=2 (approximately 95%)

7. Evaluate the expanded uncertainty
   a. The Laboratory evaluated the data and used Pareto charts to help visualize the significance of the contributing sources of uncertainty. The Laboratory plans to
reevaluate the budget on an on-going, periodic basis or when there is a significant change in the measurement process or instruments.

8. **Report the uncertainty**
   
a. The estimated measurement uncertainties will be reported by the Laboratory in accordance with the procedures in the Comparative Evidence Unit Technical Manual.

b. The estimated uncertainty of the measurement has been calculated with approximately a 95% confidence using the root sum squares method. The uncertainty estimate includes type A uncertainty components (assuming a normal distribution) and type B uncertainty components.

C. Estimated Comparative Evidence Measurement Uncertainties:
   
1. **Overall Firearm Length (steel ruler) Budget: ± 0.155 inches**
2. **Firearm Barrel Length (Hott Rods) Budget: ± 0.103 inches**
3. **Trigger Pull Budget: ± 0.490 pounds**
4. **Leica Disto Budget:** ± 0.121 inches

**Traceability of Firearm Length Standards**

- **SI (through NIST)**
- **Steel Ruler & Hot Rod™ Calibration**
  - (Performed by ISO 17025 accredited Hanson-Wyatt)
- **Outside Lab**
- **Inside Lab**
- **Steel Ruler & Hot Rod™**

**Instrument Readability**
- Based on the resolution of divisions on the measurement scales (steel ruler and Hot Rod™) and known error associated with scale offset on Hot Rod™

**Process**
- Uncertainty of the measuring process based on laboratory procedure for measuring firearm length and barrel length and variability between examiners determined by in-house experiments

**Temperature Effects**
- Temperature effects have been determined to be insignificant based on manufacturer’s specifications and environmental controls

**Measurement Results**
- The firearm and barrel lengths with the associated uncertainties of each of the components

END OF DOCUMENT
I. Policy: Firearm length standards (steel ruler and Hott Rods) will be calibrated and checked to ensure their reliability and accuracy. The following procedures describe the handling and use of these standards.

A. New length standards

1. A length standard that is new to the laboratory will be calibrated before being used in casework.

B. Annual Calibration

1. The length standards in the Comparative Evidence Unit will be calibrated annually.

2. The laboratory will maintain copies of the calibration certificates for the period defined in FSD.44.

3. The external calibration service should label the length standards or their proximal containers to indicate the calibration status, including the last calibration date and the recommended date for the next calibration.

C. Instructions for measuring overall firearm length using the steel ruler length standard.

1. The steel ruler is used to measure the overall length of a firearm during casework in the Comparative Evidence Unit. To obtain accurate length measurements within the calculated uncertainties (see Uncertainty of Measurement policy, CE.34), use the steel ruler in the following manner:

   a. Remove the calibrated steel ruler (Starrett model C604R 48" ruler) from its container.

   b. Visually check to ensure the ruler is damage free before continuing. Notify the unit supervisor if the ruler is damaged.

   c. Place long axis of ruler perpendicular to table edge.

   d. Place long axis of firearm to be measured parallel and adjacent to long axis of ruler.

   e. Align end of ruler and end of firearm with table edge.

   f. Take the reading on ruler that corresponds to the point on the firearm that is the farthest from the end aligned with the edge of the table (e.g. crown of muzzle). This measurement includes any accessories that extend beyond the
end of the barrel if they are permanently attached (i.e. through the use of a tool).

g. Measurements will be read and recorded to the nearest 1/8 inch, unless they are within +/- one inch of the relevant statutory dimensions (16, 18, 26, or 30 inches), in which case they will be read and recorded to the nearest 1/16 inch (rounding up). Fractions used in reported results will be expressed with the lowest common denominator. Any bias, determined during calibration of the length standard, will be accounted for in the measurement result. See CE.34 for reporting information.

h. If firearm has a collapsible or readily removed stock, take one measurement with the stock fully extended and one with the stock collapsed/removed.

D. Instructions for measuring firearm barrel length using the Hott Rod length standards.

1. Hott Rods™ are used to measure the barrel length of a firearm during casework in the Comparative Evidence Unit. To obtain accurate length measurements within the calculated uncertainties (see Uncertainty of Measurement policy, CE.34), use the Hott Rods™ in the following manner:

a. Remove the appropriate calibrated Hott Rod from its container. There are two types/sizes available, depending on the caliber of the barrel to be measured: .22 caliber and .30 caliber +.

b. Visually check to ensure the Hott Rod is damage free before continuing. Notify the unit supervisor if the Hott Rod is damaged.

c. Make sure the barrel of the firearm is free of obstructions and then hold the firearm vertically, with the muzzle pointing up.

d. Place the end of the Hott Rod into the barrel until it rests on the breech face of the firearm.

e. Hold the Hott Rod so it is parallel with the long axis of the barrel.

f. Take the reading on Hott Rod that corresponds to the point on the muzzle that is the farthest from the breech face. On most unaltered, factory-produced firearms, this point will be the peak of the muzzle crown. On altered firearms, such as sawed-off shotguns where the muzzle may be uneven, this point will be that which corresponds to the maximum length of the barrel. This measurement includes any accessories that are permanently attached (i.e. through the use of a tool) to the end of the muzzle, such as flash suppressors, muzzle brakes, etc.

g. Measurements will be read and recorded to the nearest 1/16 inch (rounding up). Fractions used in recorded results will be expressed with the lowest common denominator. Any bias, determined during calibration of the length standard, will be accounted for in the measurement result. See CE.34 for reporting information.

E. Handling of Equipment:

1. The length standards will be stored, handled, used, and transported in a manner that prevents contamination, deterioration and protects the integrity of the length standards. This includes:

a. Storing the length standards in their original packaging or appropriate storage cases to prevent deterioration.
b. **Handling** the length standards with appropriate care to minimize deterioration.

c. **Using** the length standards for their intended purpose, i.e. measuring overall firearm and barrel length.

d. There are no intermediate checks required, other than a visual inspection for damage upon use.

e. **Transporting** the length standards in the appropriate containers or cases to prevent deterioration.

END OF DOCUMENT
I. LIMS may be used to create electronic notes for requests.
   A. Firearms
      1. Open the evidence tab in LIMS
      2. Set the evidence type to Firearm (see image below)
      3. Open the additional data tab by clicking the "..." button (see image below)
      4. [Image of LIMS interface with evidence and additional data tabs open]

   B. [Other types of evidence as needed]
### Ext Data for Evidence '021' of Case '98-7101'

<table>

6. Check the “Verified Prior to Repackaging” to document that the unique information on the firearm was verified against the unique information on the packaging at the time of repackaging.

7. Use the “Author Verified Unique Information” when the author of a notification report did not prepare the firearm for test firing. Checking the box documents that the author verified the unique information on the firearm.

B. Printing label for test fires
   1. Open Administration -> Crystal Reports -> Generate Reports in LIMS
   2. Change the category to Firearms and select "Firearms Label with Barcodes"
   3. Click the box and scan the barcode on the assignment notification sheet. Note, the evidence item with the evidence type set to firearm must be related to the request before this will work.
   4. Print to the Brother QL-720NW barcode printer by changing the Paper Size to "Testfire Label" and Quality to "High resolution 300 x 600 dpi"
5. Attach the label to the test-fire envelope

C. Adding Worksheets to LIMS

1. Print completed worksheets (e.g. cartridge case) using the JusticeTrax Imaging printer using the following settings:
   a. Resolution: Low 200x200 DPI
   b. File format: JPEG
   c. Filename generation: use doc name
   d. Output directory: C:\temp (or other as desired)
   e. Ensure "Save each page as a separate file" is checked under the File Formats tab
   f. Ensure "Disable group file" is unchecked under the Filename Generation tab
   g. Image size should be less than 1000 KB and should be checked prior to uploading the image

2. Switch to the attachments tab in the case view window in LIMS

3. Right-click on the appropriate request folder and select either "Add New Attachment" or "Add Multiple Attachments"

4. Any filename beginning with REQ will print first.

5. Any uploaded image file will print in alphanumeric order.

6. To view or print the electronic notes, right click on the request in the main case view and select "Edit Lab Notes" then the printer icon.

D. Ballistic Leads

1. The same steps in C will be repeated to archive the PDF of a NIBIN Lead into the notes as images.

E. Service types

1. Ballistic Imaging requests should be completed with electronic notes.

2. Electronic notes may be used to create the notes for other service types. Image the worksheets and any other notes into LIMS by following the procedure in step C above.

END OF DOCUMENT
I. Technical responsibility for the Comparative Evidence Unit involves both the Firearm/Toolmark and Footwear/Tire disciplines. The individual with technical responsibility may be the Unit Supervisor, an analyst, or both, depending on the qualifications of the individuals.

A. Roles and Responsibilities: The Technical Lead will work closely with the Unit Supervisor on quality issues and be responsible for the following duties:

1. Oversee the technical operations of the discipline.
2. Oversee Quality Assurance of the discipline.
3. Evaluate and document the approval of all validations and methods, and approve new or modified procedures.
4. Review and approve training records and qualifications for new hires.
5. Review, update, and technically approve unit procedures as needed.
6. Review and approve training, quality assurance measures, and proficiency testing program.
7. A newly appointed Technical Lead will be responsible for reviewing relevant validation studies and methodologies currently used by the discipline.
8. Perform technical and administrative review of casework.
9. Perform (or oversee) and technically approve validations.
10. Assist in assigning and administering proficiency and competency tests, including verification of correctness of test results.
11. May recommend suspension of casework for an individual or for the discipline.

B. Qualifications: The Technical Lead must be a full time employee of the Laboratory and meet FSD.03 requirements for experience.

C. Authorization: The Technical Lead will meet the same requirements for authorization to conduct casework as other examiners.

END OF DOCUMENT
I. Introduction

A. This manual is designed to guide a trainee through the various areas of knowledge integral to the field of firearm and toolmark identification. It is imperative that the trainer and trainee strive to achieve the following objectives in a timely manner:

1. To independently examine submitted firearms and create items used for ballistic database entry and subsequent testing;

2. To independently examine and compare evidence relating to firearm and toolmark identification;

3. To independently render an opinion and reach conclusions relating to examinations and comparisons;

4. To provide expert testimony in court in matters involving firearm and toolmark identification in a professional, competent, and impartial manner.

B. There is a moral and ethical obligation incumbent upon firearm examiners to prepare themselves technically and professionally during training in order to be able to perform casework in accordance with policy.

C. A trainee is expected to become familiar with all pertinent unit equipment and instruments, the Comparative Evidence Technical Procedures Manual, the Division Manual, the Quality Manual, and the Safety Manual. Study will include the required and suggested readings listed in each module. Integral to the course of study will be job shadowing unit personnel who have special expertise in certain areas.

1. The minimum qualification for an analyst to perform firearm and toolmark identifications is a bachelor's degree in a natural science and successful completion of the appropriate training modules.

2. The minimum qualification for an analyst to perform all other firearms casework is a high school diploma (or equivalent) and successful completion of the appropriate training modules.

D. The trainee is required to document their training as outlined in each module.

1. This documentation may take the form of a training binder, which may consist of handwritten notes, word documents, charts, graphs, photographs, photocopied material, etc.
E. Practical exercises are required to demonstrate an understanding of the knowledge and understanding of training elements. Practical exercises should be administered using test cases in LIMS for trainees to document as mock casework and demonstrate knowledge of Division and unit requirements for case records and reports. Mock casework will be evaluated to provide an assessment of the trainee’s progress through the training module.

F. A moot court exercise will test the trainee's knowledge and comprehension of the technical material and their ability to adequately convey the information. This will typically be held at the conclusion of the Firearms Identification training module and will be the assessment for the Testimony, Report Writing, and Professionalism training module (CET.04).

II. Assessment for Previously Qualified Examiners

A. The Forensic Manager and CE Supervisor will interview the employee in detail upon assignment to the unit. The focus will be on past training, experience, education, published articles, and other credentials so that the employee's knowledge, skills, and abilities can be evaluated. Based on this information, a training plan will be developed to address any areas upon which the new employee lacks training. A competency test will be administered before the previously qualified examiner is authorized to perform casework.

III. Progression through the Training Manual

A. The training manual is divided into modules which have varying criteria for successful completion. Refer to each module for its assessment criteria. Completion of each module will be documented on a module documentation form by the trainer.

1. Modules that require a competency test will conform to FSD.21 for competency test requirements.

   a. The trainee will be informed of the passing requirements for each competency test prior to beginning the competency test. Typically 80% is the minimum passing score.

2. A trainee may be authorized to perform casework after successful completion of certain modules.

B. The estimated time frame for a trainee to complete all modules is two uninterrupted years.

C. The trainee will be informed of a timeline for expectations regarding the completion of each module.

D. The effectiveness of initial training will be monitored by the CE Supervisor in one or more of the following ways:

   1. Providing feedback to the trainee after completion of initial training modules.
   2. Soliciting feedback from the trainee regarding the initial training modules, including discussion about the practical exercises, required readings, and study questions.
   3. Performing technical or administrative review of initial casework produced by trainee.

IV. Continuing Education

A. All analysts should participate in continuing education to broaden and/or maintain their skills and expertise in the firearm and toolmark discipline. and document all of the training as outlined in QA.12. External training courses or programs including, but not limited to,
the ATF National Firearms Examiner Academy (NFEA) or the CCI Firearms and Toolmark Examiners Academy may be attended by the trainee and used to supplement or substitute for some of the training assignments and exercises contained in this manual. The effectiveness of on-going training will be monitored by the CE Supervisor in one or more of the following ways:

1. Requiring a teach back from the analyst attending the training.
2. Providing feedback regarding the training, either in a unit meeting or with one-on-one discussion with the CE Supervisor.
3. Evaluating proficiency test results.
5. Reviewing court testimony and court critiques.

V. Readings

A. The reading list in each module provides the following:

1. Gain knowledge for use in completing practical exercises and answering study questions (required readings)
2. Gain additional depth in the particular subject area (suggested readings)
3. Gain practice locating reference materials for future use (both)

B. The trainee is responsible for knowing the information contained in the required readings. The trainee is responsible for knowing that additional resources exist and how to locate them; a sampling of additional resources is listed in the suggested reading section. A reading log will be kept by the trainee documenting what books, journals, articles, etc... have been read. This log can be maintained electronically or in hard copy.
I. This module will provide the trainee with the knowledge, skill, and ability to use the variety of instruments and equipment in the Comparative Evidence Unit.

A. Objectives

1. To acquaint the trainee with the instruments and equipment in the Comparative Evidence unit.

B. Study Questions

1. What is the difference between compound, stereo, and comparison microscopes?
2. How does the laboratory conduct a magnification check on the comparison microscope?
3. What are the advantages and disadvantages of the different light sources available?
4. How often must the digital scales have a performance check conducted?
5. When must the length standards be used in casework?

C. Practical exercises

1. Using each type of light source in the field of view on a comparison microscope, note the differences in the quality of each using the following different surfaces: lead bullets, jacketed bullets, various types of cartridge cases, and various types of surfaces containing impressed and striated toolmarks. Manipulate the light sources with respect to angle and vary the intensity of the light source when possible. Gain an appreciation for the effects of varying the angle and intensity for each light source on each type of surface. Discuss this with the trainer.

2. Set up a comparison microscope for your vision requirements and focus the dividing line.

3. Perform a magnification check on a comparison microscope.

5. Demonstrate the correct way to use length standards to measure overall length and barrel length using at least ten long guns.

D. Reading
1. **Required**
   

c. AFTE Glossary (latest version)

2. **Suggested**

E. Assessment

1. Successful completion of this instrumentation portion of this module will involve:
   a. Observation of the trainee successfully:
      i. performing a performance check on a digital scale
      ii. magnification check on the comparison microscope
   b. The trainee successfully answering the study questions.

2. Successful completion of length measurement portion of this module will involve competency testing. The competency test may be incorporated into another competency test (e.g. function) or administered as a stand-alone competency test.
   a. Prior to receipt of the competency test, the analyst will be provided with the criteria for successful completion of the competency test for internal components.
   b. A successful competency test will result in authorization of the trainee to perform length measurements in casework using the equipment specified on the authorization.

END OF DOCUMENT
I. This module will provide the trainee with the knowledge, skill, and ability to safely handle firearms. The trainee shall, when available, take the CCI Firearms Safety class, though it is not required to complete this module. A lecture will provide the basis for understanding how to render firearms safe.

A. Objectives
   1. To safely handle firearms
   2. To be aware of evidence handling concerns and prevent any deleterious change from occurring
   3. To be able to render loaded firearms to a safe condition

B. Study Questions
   1. What is the correct order to safely unload most modern firearms?
   2. What is the difference between an accidental and negligent discharge?
   3. What types of evidence may be present on a firearm found at a crime scene?
   4. How can blackpowder firearms be unloaded?
   5. What do you need to document when unloading a firearm that was accepted into the laboratory without an "Unloaded" sticker?

C. Practical Exercises
   1. Safely handle a variety of firearms (at least 40) under the direction of a member of the Comparative Evidence Unit.
   2. Safely test fire a variety of firearms (at least 10, including a revolver, semiautomatic pistols and rifles, a bolt-action rifle, a pump-action shotgun, and a fully-automatic firearm) under the direction of a member of the Comparative Evidence Unit or as part of the CCI Firearms Safety Class. This exercise must include simulated failures.

D. Reading
   1. Required

c. Handgun Safety & Design, Gun.03.

d. A Guide to Firearm Safety, Gun.05.

2. Suggested

E. Assessment

1. Successful completion of this module will involve:

   a. Successful completion of the practical exercises.

   b. The trainee successfully answering the study questions.

   c. A review of the trainee's reading log.

END OF DOCUMENT
I. This module will provide the trainee with the foundation for preparing clearly-written reports, providing competent court testimony, displaying a professional demeanor, and a thorough understanding of ethics. A mock court exercise will be conducted in conjunction with other modules.

A. Objectives

1. To provide the trainee with the foundation for preparing clearly-written reports, giving thorough and competent testimony, and displaying a professional demeanor.

2. To provide the trainee with the framework for a professional and ethical career in forensics.

3. To provide the trainee with an understanding of legal procedures and the presentation of evidence in court.

4. To hold a mock court exercise with the trainee (this may be performed in conjunction with other modules).

B. Study Questions

1. What are the division and unit policy requirements for content in a laboratory report? In the notes?

2. Define the following terms and phrases: Expert witness, reasonable degree of scientific certainty, practical certainty, hearsay, opinion, voir dire, Daubert hearing.

3. What legal procedures govern the presentation of evidence in court?

4. List the most common objections that may be raised during expert testimony along with their legal basis.

5. What are the ANAB Guiding Principles of Professional Responsibility? What do you consider to be the key points in this document?

6. What are the Division requirements for courtroom testimony monitoring?

7. At what point when providing general knowledge testimony as an expert witness must you potentially resist answering further questions because doing so would, per policy, require a lab report to have been previously issued?

C. Practical exercises
1. Discuss with your trainer the policy requirements regarding note taking.
2. Discuss with your trainer the similarities and differences regarding criminal and civil testimonies and discoveries.
3. Read through copies of Firearm Identification reports written by at least two different examiners in the Comparative Evidence Unit.
4. Observe an examiner’s testimony and write a synopsis of the experience (if possible).
5. Prepare your responses to a list of potential questions that could be asked during voir dire.
6. Discuss with several examiners their best and worst testimony experiences. Discuss common themes with your trainer.
7. Become familiar with the Statement of Ethical Responsibilities and sign a personal copy.
8. Review the AFTE and CAC Codes of Ethics along with their enforcement procedures. Prepare answers for a series of proposed ethical dilemmas provided by your trainer for review with your trainer.
9. Participate as an "expert witness" in a mock court exercise based on one of the trainee's mock cases from the Identification training module.

D. **Reading**

1. **Required**

2. Suggested

Assessment

Successful completion of this module will be met by successfully completing the study questions and practical exercises, culminating in satisfactory performance during the mock court exercise, typically performed in conjunction with the firearm identification module CET.10.

END OF DOCUMENT
The module will provide the trainee with the ability to group cartridge cases based on class characteristics, safely prepare a firearm for test firing, and use the IBISTRAX-HD3D instrument to access the National Integrated Ballistic Information Network (NIBIN). The ballistic imaging system grants the ability to rapidly search through a database of hundreds and thousands of cartridge cases and test-fired cartridge cases to potentially link crime scenes.

A. Objectives
   1. To provide the trainee with the ability to determine the minimum number of firearms represented by the recovered cartridge cases based on their class characteristics.
   2. To provide the trainee with the ability to safely examine firearms and create test fires.
   3. To provide the trainee with the ability to acquire cartridge cases into NIBIN via IBISTRAX-HD3D.
   4. To provide the trainee with the ability to review correlations.

B. Study Questions
   1. What information does the ballistic imaging system use to determine the scope of their searches?
   2. What is the correct orientation for firing pin drag?
   3. What types and calibers of firearms are acceptable for entry into the laboratory's ballistic imaging system?
   4. What marks are created during the cycle-of-fire? What marks can be imparted onto a cartridge case through cycling a cartridge without firing it?
      a. Compare and contrast what marks may be present on cartridge cases fired in a recoil-operated pistol versus cartridge cases fired in a blowback-operated pistol.
   5. What types of breechface marks appear on fired cartridge cases? What are the types of firing pin shapes found on cartridge cases from a laboratory perspective? Are those the same in NIBIN?
      a. What other types of marks appear on the head of the cartridge case that may be useful to determine the number of firearms present?
   6. What may cause a magazine to hold more cartridges than its stated capacity?
C. Practical Exercises

1. With your trainer, examine sets of cartridge cases with the same class characteristics and evaluate the different types of marks present.

2. Group cartridge cases by class characteristics using the stereomicroscope or comparison microscope.

3. Safely inspect, document, and test fire a variety of firearms as selected by your trainer.
   a. Determine the magazine capacity for these firearms and additional magazines as selected by your trainer.

4. Receive hands-on training with the system, either by the company’s trainers or by a trained member of the Comparative Evidence Unit staff. Part of that training will be to scan training cartridge cases into the system to learn the step-by-step entry procedures and perform correlations.

D. Reading

1. Required
   c. IBISTRAX-HD3D training manual, latest version.
   d. Bartocci, C.R., “Class Characteristics of the 7.62 x 39mm Cartridge, Telling Whether a Fired Cartridge Case was Fired in an SKS or AK Type Rifle,” AFTE Journal, 2002; 34(2): 144-147.

2. Suggested
   c. “Case Study” The Boston Gun Project and Operation Ceasefire”, Forensic Technology, 2005 publication.
E. **Assessment**

1. Successful completion of this module will involve:
   a. The trainee successfully answering the study questions.
   b. The trainee successfully completing the practical exercises.
   c. The trainee successfully completing a competency test.

   1. Prior to receipt of the competency test, the analyst will be provided with the criteria for successful completion of the competency test for internal components.

   2. A successful competency test will result in authorization of the trainee to perform ballistic imaging casework using the equipment specified on the authorization.

END OF DOCUMENT
I. This module will provide the trainee with the background, history, development, and trends related to firearms.

A. Objectives

1. To provide the trainee with a timeline of developments in firearms and ammunition.
2. To provide the trainee with general knowledge of forensic science.
3. To gain knowledge of the history and significance of the Association of Firearm and Tool Mark Examiners (AFTE), to include the following:
   a. History
   b. Criteria for membership
   c. AFTE Glossary
   d. AFTE Journal and its peer review process
   e. Online resources (Headstamp Guide, SWGGUN Admissibility Resource Kit, searchable AFTE Journal index, Forums, etc.)
4. To gain knowledge of the history and the current status of ballistic imaging systems such as IBISTRAX-HD3D and Evofinder

B. Study Questions

1. What types of evidence may be encountered on a submitted firearm? Why is it important to examine for these types of evidence before beginning an examination.
2. Compare and contrast usage of the terms Firearm Identification and Ballistics.
3. Is the forensic science discipline of Firearm and Toolmark Identification an art or science?
4. What are the types of conclusions that can be reached in firearm identification comparisons?

C. Practical Exercises

1. Develop a timeline on the history of firearms and ammunition. Focus on the significant designs changes and technology developments.
2. Visit each unit of the laboratory to understand the scope of their work. What similarities exist between the various forensic science disciplines? What differences exist? What forensic science disciplines are not performed by the laboratory? Discuss your observations with your trainer.

D. **Reading**

1. **Required**

   a. **Books**

   b. **AFTE Journal**

   c. **Other Professional Journals**

   d. **Other Documents**

2. **Suggested**

   a. **Books**

b. **AFTE Journal**

c. **Other Journals**

d. Other Documents

E. Assessment

1. Successful completion of this module will involve:

   a. A review of the reading log. Entries are required to reflect the familiarity with each reading.

   b. The trainee successfully answering the study questions.

   c. The trainee successfully completing the practical exercises.

END OF DOCUMENT
I. This module will familiarize the trainee with the different types of class characteristics found on fired bullets, cartridge cases, and shotshells. This will provide the trainee the ability to determine a list of firearms that could have fired the bullet, cartridge case, or shotshell.

A. Objectives

1. To provide the trainee with the knowledge of basic class characteristics of bullets, cartridge cases, and shotshells for the purpose of determining a list of potential firearms that could have fired the bullets, cartridge cases, and shotshells. This training will include the following:

   a. Become familiar with the various resources available to determine the manufacturer/marketer of a particular cartridge, cartridge case, or shotshell based on its headstamp.

   b. Become familiar with the types of marks typically found on reloaded ammunition.

   c. Become familiar with the ammunition storage areas in the unit.

   d. Become familiar with the various reference materials available in the laboratory, including the FBI's General Rifling Characteristics (GRC) File, and how to use them to search for information.

2. To provide the trainee with the ability to determine the minimum number of firearms represented by fired ammunition components based on class characteristics.

B. Study Questions

1. Define the following terms or phrases:

   a. Slippage

   b. Shaving

   c. Obturation

   d. Leading edge and trailing edge

   e. Gas cutting
f. Impression  
g. Striation  
h. Individual characteristics  
i. Subclass characteristics  
j. Class characteristics  
k. Rifling characteristics  
l. Rifling impressions  
m. Corrosion  
n. Leading  
o. Cycling marks  
p. Cycle-of-fire marks  

2. What are the importance and limitations of the following bullet characteristics with respect to caliber determination?:  
   a. Weight  
   b. Diameter  
   c. Manufacturer (if it can be determined)  
   d. Rifling characteristics (number, direction of twist, width)  
   e. Pitch of rifling  
   f. Jacket construction/composition  

3. How has the GRC File been developed over the years?  

4. Does a list of potential makes and models of firearms generated from the GRC contain all possible firearms with same class characteristics as those searched? Why or why not?  

5. What reference points are used to properly measure the dimensions of land and groove impressions on a fired bullet?  

6. What is the formula for estimating the caliber of a damaged fired bullet if the total number of land and groove impressions and at least one pair of land and groove impression measurements can be determined?  

7. What is a good resource to help determine nominal caliber from a lead core?  

C. Practical exercises  
   1. Using provided fired bullets (both pristine and damaged), demonstrate the ability to determine their caliber, manufacturer, and rifling characteristics.  
   2. Using provided cartridge cases, demonstrate the ability to determine any make/model information for the firearm that fired them.  
      a. Combine information from the provided bullets (#1) and cartridge cases (#2) using limited universe assumptions.
3. Discuss with your trainer the feasibility of determining caliber and/or the rifling characteristics of a fired bullet from an examination of a bullet hole in metal.

4. Write a short report to describe what types of marks may appear on reloaded ammunition components.

5. Discuss with your trainer the ability to recognize and document gun powder particles that may be encountered in casework.

6. Visit at least one ammunition-manufacturing facility such as Remington, Federal, or Winchester to observe the manufacture of rimfire and centerfire cartridges and shotshells. Take detailed notes of the manufacturing processes. Write a report on what you learned, and provide an oral presentation to the Unit. This exercise is optional due to a lack of nearby manufacturing facilities.

D. Assessment

1. Successful completion of this module will be assessed by the following:
   a. Successfully answering the study questions.
   b. Successfully completing the practical exercises.
   c. A review of the trainee's reading log.
   d. Competency testing.
      i. Prior to receipt of the competency test, the analyst will be provided with the criteria for successful completion of the competency test.
      ii. A successful competency test will result in authorization of the trainee to perform Make/Model Determination casework.

E. Reading

1. Required (Note: items denoted by [Reference] are intended as general references only and do not need to be read in their entirety by the trainee)
   a. General
      i. Barnes, F.C., Cartridges of the World, various editions. [Reference]
   b. General Rifling Characteristics/Class Determinations/Bullet Markings
i. Bartocci, C.R., “Class Characteristics of the 7.62 x 39mm Cartridge, Telling Whether a Fired Cartridge Case was Fired in an SKS or AK Type Rifle,” AFTE Journal, 2002; 34(2): 144-147.

c. Shotshell Components - General

d. Shot Pellets

e. Buffer Material

f. Manufacturing Marks

2. Suggested

a. General Rifling Characteristics/Class Determinations/Bullet Markings

b. **Comparison Techniques/Experiments**

c. **Automated Systems**

d. Shotshell Components - General

e. Shot Pellets

f. Shotshell Slugs

g. Shotshell Wadding

h. Buffer Material

i. Manufacturing Marks

END OF DOCUMENT
I. This module will provide the trainee with a thorough understanding of machining processes and how they impact forensic firearm and toolmark analysis.

A. Objectives

1. To provide the trainee with a thorough understanding of machining processes and their impact on firearm and non-firearm toolmark identification casework.

B. Study Questions

1. Prepare a short report describing each process and how it is used in the manufacture of firearms:
   a. Shaping
   b. Planing
   c. Drilling
   d. Reaming
   e. Turning
   f. Boring
   g. Milling—include both face milling and peripheral (slab) milling broaching
   h. Investment casting

2. Prepare a short report describing each rifling method and its impact on casework
   a. Broach
   b. Button
   c. Hammer forging
   d. Hook method
   e. Scrape method
   f. ECM
3. Prepare a short report describing each term as they relate to firearm manufacture or firearms identification
   a. Chambering
   b. Crowning
   c. Forcing cone
   d. Bore
   e. Choke
   f. Choke tubes

C. Practical Exercises
   1. Using samples provided by your trainer, demonstrate the ability to identify the machining process used to create each item.
   2. Watch the provided videos and prepare a short description of each machining process.

D. Assessment
   1. Successful completion of this module will involve:
      a. The trainee successfully answering the study questions.
      b. The trainee demonstrating an understanding of the machining processes via the practical exercises.
      c. A review of the trainee's reading log.

E. Reading
   1. Required
      a. Books
         iv. Moltrecht, K.H., Machine Shop Practice Vol 1 & 2
      b. AFTE Journal

c. **Videos**

i. Provided by your instructor

2. **Suggested**

a. **Books**

iii. Moltrecht, K.H., Machine Shop Practice Vol 1 & 2

b. **AFTE Journal**

END OF DOCUMENT
I. This module will provide the trainee with the ability to test firearms for operability and determine whether firearms or firearm components meet relevant statutory definitions in the State of California.

A. Objectives

1. To learn terminology associated with ammunition, its manufacture, and class characteristics of firearm-produced toolmarks left on fired ammunition components
2. To learn the difference between the true, nominal, and specific caliber of ammunition
3. To become familiar with the class characteristics of cycle-of-fire marks left by various known makes of firearms on bullets and cartridge cases fired from them
4. To provide the trainee with the history, understanding, and familiarity with all types of commonly encountered firearms
5. To provide the trainee with the knowledge, skills, and abilities to understand various firearm operating systems and types of safeties
6. To gain the ability to safely test fire firearms to determine operability
7. To become familiar with general procedures and reference materials for firearm disassembly and reassembly
8. To gain the knowledge and ability to classify features to determine whether a submitted firearm meets the legal definition of an Assault Weapon per the California Penal Code
9. To gain the ability to determine whether a device meets the legal definition of a silencer per the California Penal Code
10. To become familiar with the procedure for performing and reporting ejection pattern analysis

B. Study Questions:

1. Define the following terms or phrases as they relate to modern ammunition manufacture:
<table>
<thead>
<tr>
<th></th>

</tbody>
</table>
2. What does the term "Gauge" refer to and how is it determined?
3. Define each of the following basic types of firearms:
   a. Handgun
      i. Revolver
      ii. Pistol
      iii. Derringer
   b. Long gun
      i. Rifle
      ii. Shotgun
         1. Single-shot
         2. Side-by-side
         3. Over-under
         4. Pump-action
      iii. Carbine
      iv. Machine gun
      v. Submachine gun
   c. Muzzle-loading firearm

4. Define each of the following firearm operating modes:
   a. Single action
   b. Single-action only
   c. Double action
   d. Double-action only

5. Define each of the following types of operating systems, to include the loading of cartridges and the subsequent movement of the cartridge case and/or bullet after firing. Give an example of each:
   a. Revolving
   b. Semiautomatic
   c. Automatic
   d. Gas-operated
   e. Blowback
   f. Delayed blowback
   g. Bolt action
   h. Pump-action/slide-action
   i. Lever action
6. What is the difference between a hammer and a striker?

7. Describe the difference between the following terms:
   a. External safety vs. Internal safety
   b. Active safety vs. Passive safety

8. Describe each of the following types of firearm safeties, including how they operate, and give an example of a firearm that employs each one. Classify each according to the terms in 7a and 7b above:
   a. Thumb lever
   b. Rebound slide
   c. Magazine safety
   d. Hammer block
   e. Transfer bar
   f. Crossbolt
   g. Rolling block
   h. Selector switch
   i. Trigger disconnect
   j. Sear engagement
   k. Trigger pull
   l. Trigger safety

9. Define the following terms relating to firearm malfunctions:
   a. Excessive headspace
   b. Bore obstruction
   c. Barrel bulge
   d. Broken extractor
   e. Hammer push-off
   f. Trigger shoe
   g. Slam-fire
   h. Inadequate/improper sear engagement
i. Defective safety
j. Blown primer
k. Stovepipe
l. Double-feed
m. Rail splitting
n. Hairline cracks
o. Improper timing
p. Excessive pressure
q. Dented barrel
r. Jar-off
s. Failure to feed
t. Failure to extract

10. What tests can be performed to determine if a firearm can be made to fire without pulling the trigger?

11. What are considered the normal ranges for the trigger pulls of a single and double-action semiautomatic pistol?

12. What is a "hair trigger"?

13. Define the features of an assault weapon as defined by the California Penal Code.

14. What is the legal definition of a sound suppressor? Individually define the features that may be present in a suppressor.

15. What is the difference between a barrel extension and a suppressor?

16. Describe how you would examine a suppressor to determine if it had been fired through.

17. List some potential causes of unintentional discharges. Can a firearm that is determined to function normally be involved in an accidental discharge? Why or why not?

C. Practical Exercises

1. Demonstrate your ability to distinguish between the following terms:
   a. True caliber
   b. Nominal caliber
   c. Caliber designation

To do this, obtain at least six different cartridges from the following cartridge “families”: .22 caliber, .30 caliber, .32 caliber, and .38 caliber. Identify each one as to caliber designation and explain/demonstrate the meaning of true caliber and nominal caliber for each. This assignment will require you to use the laboratory’s ammunition standards and print reference files. For each
cartridge, obtain two standards, disassembling one and leaving the other intact. Use these to demonstrate the differences in cartridge case sizes and shapes, as well as variations in bullets (weight, jacketing, design, cannelures, true caliber, etc.).

2. Give five examples of each of the various methods used in the past for American caliber designations within caliber "families", including powder charge, velocity, manufacturer's name or designer's name, year of adoption, metric designation, etc. Contrast the European metric designators currently used with the less formalized American system.

3. Disassemble a 12 Gauge shotshell and examine the components. Discuss with your trainer.

4. Sketch the cross-section of Berdan and Boxer primers, showing their relationship to the head of the cartridge. Briefly discuss their development and practical significance.

5. Describe and/or safely demonstrate the potential for cartridge interchangeability between 380 Auto, 9mm Makarov, 9mm Luger, 40 S&W, and 357 SIG caliber firearms.

6. Examine the Glock 17 Gen4 cut-away model in the laboratory's Firearms Reference Collection. Note the operation of the firearm's striker and related components; describe how this system differs from a conventional single and double-action firearm mechanism. What does Glock call this proprietary type of action?

7. Using various firearms from the laboratory's Reference Collection, demonstrate your knowledge of firearms nomenclature by naming the various external and internal firearm components for your trainer.

8. Obtain manufacturer information and exploded diagrams for the following firearms as indicated below (note the listed exceptions that only require handling for familiarization). Using the laboratory's Firearm Reference Collection, complete a firearm worksheet and test fire each selected firearm, observing the class characteristics both on the firearm and on the test fires. Where possible, field strip each firearm and become familiar with the components using literature references or online video tutorials.

   a. .22 caliber rifles (document the 10/22, become familiar with the operation of the others)
      i. Ruger 10/22 semiautomatic rifle
      ii. Remington Model 550 (or other .22 caliber bolt-action rifle)
      iii. Winchester Model 62A (or other .22 caliber slide-action rifle)

   b. .22 caliber pistols and revolvers (pick one to document, become familiar with the operation of the others)
      i. Ruger Standard Model
      ii. Jennings J-22
      iii. H&R Model 999 (or other .22 caliber top-break revolver)
      iv. Ruger Single-Six (or other .22 caliber single-action revolver)
c. Derringers (become familiar with the operation)

d. 25 Auto caliber semiautomatic pistols (pick one to document, become familiar with the operation of the others)
   i. Beretta 950B or BS
   ii. Raven P-25 or MP-25
   iii. Colt 1908

e. 380 Auto pistols (pick two to document, become familiar with the operation of the others)
   i. Walther PPK or PPK/S
   ii. Sig Sauer P230
   iii. Browning BDA-380
   iv. AMT Backup

f. Medium/large caliber pistols
   i. 9mm Luger (9x19mm) caliber
      1. Smith & Wesson M&P-9
      2. Beretta 92 series
      3. Hi-Point Model C
      4. Lorcin L9MM
      5. Ruger P89 or P95
      6. Intratec TEC-9
      7. H&K P7 M8
   ii. 357 SIG caliber
      1. Glock 31C
   iii. 40 S&W caliber
      1. Sig Sauer P226 or P229
      2. Smith & Wesson SW40V (not VE)
      3. Springfield XD-40
      4. Beretta PX4 Storm
   iv. 45 Auto caliber
      1. Colt 1911 (any model)
      2. Kimber or Para Ordnance 1911-type (any compact model with bull barrel)
      3. Glock (any model)
v. Miscellaneous calibers
   1. Desert Eagle (any caliber: 357/44 Mag/50 AE)
   2. FN Herstal Five-Seven

g. Medium/large caliber revolvers
   i. 38 Special/357 Magnum caliber (pick two to document, become familiar with the operation of the others)
      1. Smith & Wesson Model 15 (38 Special)
      2. Colt Python (357 Mag)
      3. Ruger GP-100 (357 Mag)
      4. Dan Wesson Arms Model 15 (357 Mag)
   ii. 44 Magnum (pick one to document, become familiar with the operation of the others)
      1. Smith & Wesson Model 29
      2. Ruger Redhawk
   iii. Miscellaneous calibers
      1. Taurus Judge or Public Defender (45 Colt/.410 gauge)

h. Rifles
   i. 30-30 caliber (any model; e.g., Winchester Model 94)
   ii. 7.62x39mm caliber AK-type
   iii. 7.62x39mm caliber SKS-type
   iv. 223 Rem/5.56x45mm caliber AR-type

i. Shotguns (pick one to document, become familiar with the operation of the others)
   i. Remington 870
   ii. Mossberg 500
   iii. Browning Auto-5
   iv. Benelli M1 Super 90
   v. Weatherby Orion (or other top-break model)
   vi. "Streetsweeper" type with a rotary magazine (any model)

9. Become familiar with the operation of the following firearms:
   a. Luger P08
   b. 303 Lee Enfield
   c. M1 Garand
d. M14/M1A

e. Thompson submachine gun

f. H&K MP5

g. 9mm Makarov caliber pistol

10. Familiarize yourself with the laboratory's literature references regarding ammunition and firearms. Ask your trainer for assistance if necessary.

11. Familiarize yourself with the laboratory's collection of firearm safety recall warnings.

12. As available, attend one or more armorer’s courses.

13. Locate and document proof and inspector marks on at least three firearms from the laboratory's reference collection. Research what the marks mean.

14. Discuss the laboratory's requirement for marking firearms evidence.

15. Demonstrate the ability to recognize, document, and recover trace evidence from the bore of a firearm prior to test firing.

16. Demonstrate the proper techniques for measuring the trigger pulls of a hand gun and long gun using one of the NRA steel weight sets.

17. Discuss proper evidence handling techniques when a firearm is recovered from water. What rust removal techniques can the laboratory employ?

18. Using a pencil or cotton swab, demonstrate how an examiner can determine if a firing pin is likely functional before test firing.

19. Demonstrate how an examiner can determine if a firearm has been altered to fire fully automatic before test firing.

20. Describe how ejection pattern testing is conducted. What are the limitations? Does the laboratory regularly perform ejection pattern analysis? Why or why not?

21. Examine representative samples of sound suppressors from the armory. Become familiar with the design features of commercially-produced and improvised suppressors. Examine internal components with the borescope and discuss your observations with your trainer.

D. Assessment

1. Successful completion of this module will involve:

   a. The trainee successfully answering the study questions.

   b. The trainee successfully completing the practical exercises.

   c. The trainee successfully completing a competency test.

      i. Prior to receipt of the competency test, the analyst will be provided with the criteria for successful completion of the competency test.

      ii. A successful competency test will result in authorization of the trainee to perform Function testing casework.

E. Reading
1. **Required**

   a. **Books** (Note: Books denoted by [Reference] are intended as general references only and do not need to be read in their entirety by the trainee)

      i. **General**

      ii. **Ammunition**

      iii. **Firearms**

b. **AFTE Journal**

i. **Ammunition**

ii. **Accidental Discharge Potential/Safeties**

iii. Firearm Markings

iv. Improvised/Homemade Firearms

v. Trace Evidence Concerns

vi. Trigger Pull

vii. Ejection Pattern Analysis

viii. Sound/Flash Suppressors

2. Suggested

a. AFTE Journal

i. Accidental Discharge Potential/Safeties

ii. Firearm Markings

iii. Improvised/Homemade Firearms

END OF DOCUMENT
I. This module will provide the trainee with the ability to perform firearm identification examinations.

A. Objectives

1. To provide the trainee with knowledge, skills, and ability to perform identification examinations.

2. To provide the trainee with the knowledge, history, and significant of the Association of Firearm and Tool Mark Examiners (AFTE) including their certification program and Range of Conclusions.

3. To gain knowledge of themes from recent challenges to the admissibility of firearm identification testimony

4. To gain knowledge about recent developments including:
   a. 2008 NRC Report on Ballistic Imaging
   b. 2009 NAS Report on Strengthening Forensic Science
   c. Organization of Scientific Area Committees (OSAC) Firearms and Toolmarks Subcommittee
   d. 2016 PCAST report

5. To provide the trainee with a working knowledge of subclass characteristics, their origin, and their impact on identification casework.

6. To gain a working knowledge of current case law decisions and standards for casework.

B. Study Questions

1. When should a conclusion of inconclusive be issued? Why? What are the range of conclusions possible?

2. What machining processes often produce subclass characteristics?
   a. Generally, what types of surface will be free from subclass influence?
   b. How does an examiner evaluate for subclass?
3. What is the definition of sufficient agreement? Is there an analogy you could use to describe the concept?

4. Is it possible for experts in the discipline of Firearm and Toolmark Identification to disagree regarding their conclusions? Why or why not?

5. Do numerical criteria exist for identification conclusions on striated marks?

6. Do numerical criteria exist for identification conclusions on impressed marks? If not, why not?

7. How does "probability" relate to firearm identification?

8. What is the meaning of the term "practical certainty"?

C. **Practical exercises**

1. Develop a timeline on the history of firearm identification. Include significant court decisions, technology developments, documentation developments, and publications.

2. Using test fires from the function testing module, systematically intercompare known matches (KM) and known non-matches (KNM) and evaluate the amount of individual agreement present in each series. After comparison of the test fires from the same caliber, create test fires from at least two additional firearms of the same make/model/caliber for comparison (minimally for 9mm Luger, 40 S&W, 45 Auto, 38/357, and 380 Auto; more as directed by your trainer) using different types of ammunition. Take representative photographs of your observations during this exercise.

   a. This exercise is the foundation for understanding sufficient agreement.

3. Using the test fires from the function testing module as a reference, create a set of cartridges cycled through firearms selected by your trainer to compare the quantity and quality of cycling marks found on unfired ammunition with the quantity and quality of cycling marks found on fired ammunition. Document these comparisons on comparison worksheets and prepare a summary of your observations.

4. Select five firearms from the function testing module and fire an additional two shots using ammunition loaded with different types of bullets. Intercompare these bullets with the original test-fired bullets. Note, if additional test fires were created during the function testing module, proceed directly to the intercomparisons.

5. After the above exercises, obtain shotshells from four different “shooting scenes” from your trainer and examine them as you would a real case. Take appropriate notes and write a report as to your findings.

6. Participate in a study involving consecutively manufactured items (e.g. Brundage) if available.

7. Complete mock casework involving cartridge cases, bullets, and test fires as provided by your trainer.

D. **Assessment**

1. Successful completion of this module will involve:

   a. The trainee successfully answering the study questions.
b. A review of the reading log. Entries are required to reflect familiarity with each reading.

c. The trainee successfully completing the practical exercises.

d. The trainee successfully completing a competency test.
   i. Prior to receipt of the competency test, the trainee will be provided with the criteria for successful completion of the competency test.

e. The trainee successfully completing a mock court exercise (done in conjunction with CET.04).

2. A successful competency test will result in authorization of the trainee to perform Identification casework.

E. Reading

1. Required

   a. General

xxii. Report to the President, Forensic Science in Criminal Courts: Ensuring Scientific Validity of Feature-Comparison Methods. [Gun.64]

b. Specific Models and Mechanism Marks

c. **Firing Pin Impressions**
   

   d. **Anvil Marks**

   e. **Manufacturing Marks**

   f. **Breech Face Marks**

g. **Chamber Marks**

h. **Extractor Marks**

i. **Bunter Marks**

j. **Magazine Marks**

2. **Suggested**

   a. **General**

do. **Specific Models and Mechanism Marks**

c. **Firing Pin Impressions**

d. **Anvil Marks**

e. **Manufacturing Marks**
   
   
   
   
   

f. **Breech Face Marks**
   
   

g. **Chamber Marks**
   
   
   
   
   
   

END OF DOCUMENT
I. This module will provide the trainee with the ability to perform distance determinations.

A. Objectives
   1. To provide the trainee with the knowledge, skills, and abilities to perform distance determinations.

B. Study Questions
   1. Generally, describe the chemical processes that take place in the burning of smokeless powder, the Modified Griess test, the Sodium Rhodizonate test, and the DTO Test.
   2. What challenge does blood on clothing pose for distance determinations?
   3. What recent changes to some buckshot loads have changed the conservative “1 inch spread per yard for 00 buckshot” rule of thumb?
   4. Under what circumstances would it be advisable to perform a distance determination when the firearm was not available? What limitations would need to be included in the report?

C. Practical Exercises
   1. Demonstrate a good working knowledge of the literature by preparing a brief explanation of the following as they relate to distance determinations:
      a. Cylinder gap
      b. Intervening objects
      c. Muzzle orientation and attachments
      d. Geometric aspects to powder patterns
      e. Smokeless powder morphology and treatment
      f. Wind
      g. Barrel length
   2. Demonstrate a strong working knowledge by performing practice casework while:
      a. Preparing and using the required chemicals and test papers
b. Performing distance determination analysis on the specimens provided by the trainer.

c. Using photographs provided by your trainer, determine the muzzle to target distance

D. **Assessment**

1. Successful completion of this module will involve:
   
a. The trainee successfully answering the study questions.

b. A review of the reading log. Entries are required to reflect the familiarity with each reading.

   c. The trainee successfully completing the practical exercises.

   d. The trainee successfully completing a competency test.

   i. Prior to receipt of the competency test, the analyst will be provided with the criteria for successful completion of the competency test.

   ii. A successful competency test will result in authorization of the trainee to perform distance determination casework

E. **Required Reading**

F. Suggested

1. Books

2. AFTE Journal
   a. Gunshot Residues

b. Shot Patternning

xviii. Vincie, P., and Thornton, J., ”Quality Assurance in Shotshell Manufacture Implications for Determination of Discharge Distance,”
1985; 17(3):70.

c. Shooting Reconstruction

END OF DOCUMENT
I. This module will provide the trainee with the ability to perform serial number restorations.

A. Objectives

1. To provide the trainee with the knowledge, skills, and abilities to perform serial number restorations, to include the following:
   a. An understanding of the underlying theory behind serial number restorations
   b. The methods commonly used to obliterate serial numbers
   c. An understanding of the chemicals and chemical reactions involved in serial number restorations
   d. An understanding of the use of magnets in restoring serial numbers
   e. Proper techniques for restoring serial numbers
   f. Proper methods of documenting and reporting a serial number restoration attempt

B. Study Questions

1. Sketch a cross-section of the entire stress area above and below the indentation of a stamped item and depict what remains when the indented area is removed.

2. What are the main methods used to serialize items in the firearms industry?

3. Define the term plastic deformation.

4. Discuss grinding, over stamping, gouging, heating, welding, removal, and combinations of these alterations with your trainer.

5. What are telltale signs left by the various alteration methods? Discuss with your trainer how these signs will determine your approach to the restoration attempt.

6. Discuss surface preparation with your trainer, including its importance, the various methods, and how this step may affect the results of a restoration attempt.

7. Discuss the theory and use of magnets in serial number restorations. How does the Parker Contour Probe work and what advantages does it offer (if any) when compared with horseshoe magnets?
8. Describe, in general, the chemical reactions that take place when etching is conducted.
   a. Is the reaction rate for a stressed area faster or slower than the etching rate for the rest of the surface? Why?

9. What are the two primary references available in the laboratory for determining the format (numbering scheme) of a particular firearm's serial number?

10. What is the proper way to record and report a partial serial number restoration, where some characters are in doubt?

C. Practical Exercises
   1. Using samples provided by your trainer, attempt to restore the obliterated serial number. Check in with your trainer at each step in the process to receive feedback.
   
   2. Witness at least three serial number restoration attempts in casework by other laboratory staff members. Document the laboratory number and discuss the results with your trainer.

D. Assessment
   1. Successful completion of this module will involve:
      a. The trainee successfully answering the study questions.
      b. The trainee successfully completing the practical exercises.
      c. The trainee successfully completing a competency test.
         i. Prior to receipt of the competency test, the analyst will be provided with the criteria for successful completion of the competency test.
         ii. A successful competency test will result in authorization of the trainee to perform serial number restoration casework.

E. Required Reading
   2. Serial Number Restoration (E111) Course Materials (Binder), California Criminalistics Institute.
   5. Parker Research Corporation Operating Instructions for the Contour Probe. INSCE.01.
F. Suggested Reading

END OF DOCUMENT
I. This module will provide the trainee with the ability to perform non-firearm toolmark comparisons.

A. Objectives

1. To provide the trainee with the knowledge, skills, and ability to perform non-firearm toolmark comparisons.

2. To provide the trainee with a working knowledge of subclass characteristics, their origin, and their impact on non-firearm toolmark comparisons.

B. Study Questions

1. Discuss with your trainer the significance of examining submitted tools first for trace evidence.

2. Prepare a short description of the following machining processes:
   a. Abrasive machining—include honing, lapping, grinding, sanding, and ultrasonic methods
   b. Sawing
   c. Filing
   d. Swaging

3. What types of conclusions can be reached in cases involving toolmark comparisons where no tool is submitted? Consider such things as the type of tool, size of the tool, action employed by tool, value of toolmark for comparison purposes, and unusual toolmark features.

4. Define the following terms as they relate to toolmark identification and give three examples of tools or methods that could produce each category:
   a. Shearing
   b. Pinching
   c. Fracture
   d. Scrape mark
C. Practical Exercises

1. Select a flat-bladed tool such as a screwdriver and a pry bar. Initially, make marks in lead with both tools varying the pressure and angle of action. Compare these marks to one another. Make the same type of marks in a piece of copper or brass sheeting. Microscopically compare those in the brass or copper sheeting with the test marks in the lead. Attempt to identify the appropriate marks with the appropriate tool. Repeat making tests in lead and compare them with the original lead tests. Photograph your results and comment on the difference in the quality of marks made by each tool in each medium.

2. Using a drive pin punch, produce a set of test marks in lead and examine these two marks. Then produce an impression in a piece of brass or copper sheeting. Compare the marks in brass or copper to the lead test marks. Make a second set of tests in lead and compare those to the original lead test marks. Attempt to identify these as having been made by the same tool. Support your results by photographs.

3. Obtain an ax blade that contains numerous defects. Cut a piece of seasoned wood such as dowel rod with the ax blade and attempt to identify the blade with the cut. Insure that your test cuts are consistent with your "unknown" with respect to the orientation of the ax to the wood and the direction of the grain. Support your results with notes and photographs. Obtain a variety of wire-cutting tools and cut 1/8" thick wire solder with each. Carefully note the profile of the cut ends. Prepare a table that illustrates the class characteristics of the cut ends as related to the profile of the tool-cutting edges.

4. Repeat the previous practical exercise with files and abrasive tools, and discuss problems encountered with these types of examinations.

5. Using a saw and blade, properly document each saw blade on a worksheet. Make test cuts in lead and attempt to identify the tests to one another. Ensure that you label your tests properly with respect to the orientation of the blade. Following this examination, produce "questioned" cuts in materials such as wood, plastic, and metal. Try to compare these marks with the original lead test marks. Make more test marks in lead and repeat the comparison process to attempt to identify the "questioned" cuts to the second set of lead test cuts. Compare the original lead test marks with the second set of lead test marks. Properly document "best match" comparisons with notes and photographs.

6. Obtain a variety of wire cutting tools and cut 1/8" thick wire solder with each. Carefully note the profile of the cut ends. Prepare a table that illustrates the class characteristics of the cut ends as related to the profile of the tool cutting surface.

7. Perform mock casework using the samples provided by your trainer.

D. Assessment

1. Successful completion of this module will involve:
   
a. The trainee successfully answering the study questions.
i. A review of the reading log. Entries are required to reflect familiarity with select readings.

ii. The trainee successfully completing the practical exercises.

iii. The trainee successfully completing a competency test.

   1. Prior to receipt of the competency test, the analyst will be provided with the criteria for successful completion of the competency test.

   2. A successful competency test will result in authorization of the trainee to perform toolmark casework

E. Reading

END OF DOCUMENT
The objective of this training module is to provide the knowledge, skills, and abilities for an analyst to become competent in the footwear/tire discipline.

A. This training incorporates literature review, demonstrations, and hands-on practical exercises. Footwear or tire imprint/impression examination related classes, professional seminars, schools, and workshops can substitute or supplement this training module. No external classes can substitute for the competency test.

B. A trainee is expected to become familiar with all pertinent unit equipment and instruments, the Comparative Evidence Technical Procedures Manual, the Division Manual, the Quality Manual, and the Safety Manual. Study will include the required readings listed in the module. Integral to the course of study will be job shadowing unit personnel who have special expertise in certain areas.

1. The minimum qualification for an analyst to perform shoe/tire impression analysis is a bachelor's degree in a natural science and successful completion of the training module.

C. The trainee is required to document their training. This documentation may take the form of a training binder, which may consist of handwritten notes, word documents, charts, graphs, photographs, photocopied material, etc.

D. Practical exercises are required to demonstrate an understanding of the knowledge and understanding of training elements. Practical exercises should be administered using test cases in LIMS for trainees to document as mock casework and demonstrate knowledge of Division and Unit requirements for test records and reports. Mock casework will be evaluated to provide an assessment of the trainee's progress through the training module.

E. The Forensic Manager and Supervisor will interview the employee in detail upon assignment to the unit. The focus will be on past training, experience, education, published articles, and other credentials so that the employee's knowledge, skills, and abilities can be evaluated. Based on this information, a training plan will be developed to address any areas upon which the new employee lacks training. A competency test will be administered before the previously qualified examiner is authorized to perform casework.

F. Prior to beginning the training module, the trainer and trainee will discuss the trainee's general knowledge of forensic science.

G. The trainer and trainee will discuss the following items related to ethics:

1. ANAB Guiding Principles of Professional Responsibility.
2. CAC Code of Ethics
3. FSD Statement of Ethical Responsibility
4. Ethical scenarios.

H. Progression through training module.
   1. The estimated time frame for a trainee to complete the training module, if allowed to train full-time, is six months.
   2. The trainee will be informed of a timeline for expectations regarding the completion of the training module.
   3. External coursework (e.g., California Criminalistics Institute courses, online training programs) may be substituted for some or all of this training module. The equivalency of such coursework will be evaluated on a case-by-case basis.
   4. A competency test will be administered at the completion of the training module. The trainee will be informed of the criteria for successful completion prior to beginning the competency test.
      a. A mock court exercise will be conducted based on the mock test report completed as part of the competency test.
   5. The effectiveness of initial training will be monitored by the Supervisor in one or more of the following ways:
      a. Providing feedback to the trainee after completion of the training module.
      b. Soliciting feedback from the trainee regarding the training module, including discussion about the practical exercises, mock casework, and required readings.
      c. Performing technical or administrative review of initial casework produced by trainee.
      d. Providing annual performance evaluations.

I. All analysts should participate in continuing education to broaden or maintain their skills and expertise in the footwear/tire discipline. The effectiveness of on-going training will be monitored by the Supervisor in one or more of the following ways:
   1. Requiring a teach-back from the analyst attending the training.
   2. Providing feedback regarding the training, either in a unit meeting or with one-on-one discussion with the Supervisor.
   3. Evaluating proficiency test results.
   5. Reviewing court testimony and court critiques.

II. Introduction to Historical Developments

A. **Objective:** To introduce the trainee to the historical development of footwear and tire imprint/impression examinations, current practices of footwear and tire imprint/impression examinations, and understand the discipline's nomenclature.
B. **Practical Exercises**
   1. There are no practical exercises for this section.

C. **Evaluation of Trainee Progress**
   1. The trainer will review the reading assignments with the trainee.

D. **Reading:**
   3. Chapters 1, 2 and 3, and glossary, Tire Imprint Evidence, Peter McDonald, Elsevier Science Publishing Company, New York, NY 10010.

III. **Recording and Working with 2-Dimensional Footwear Impressions**
   A. **Objective**: The trainee will learn methods for recording 2-dimensional imprints and special methods for enhancement or visualization of 2-dimensional imprints.

   B. **Practical Exercises**:
      1. Photography of 2-dimensional imprints.
      2. Learn and demonstrate methods to develop latent imprints and methods to record them, including:
         a. Dusting with fingerprint powder
         b. Electrostatic dustprint lifter
         c. Gelatin lifter
         d. Chemical methods
      3. Learn to distinguish between examination-quality photographs of questioned evidence and those that are of limited or no value for comparison purposes.
         a. Learn to re-size/scale examination-quality photographs to natural size (1:1) using Adobe Photoshop for direct comparison with test impressions.

   C. **Evaluation of Trainee Progress**
      1. The trainer will review the reading assignments and practical exercises with the trainee.
D. **Reading**

IV. **Recording and Working with 3-Dimensional Footwear and Tire Impressions**

A. **Objective:** The trainee will learn methods for recording 3-dimensional impressions.

B. **Practical exercises:**

1. Practice photographing 3-dimensional footwear impressions

2. Practice casting (using dental stone) 3-dimensional footwear impressions in

   a. mud
b. sand

c. submerged soil

3. Discuss with your trainer the utility of casts in the comparison process.

C. **Evaluation of Trainee Progress**

1. The trainer will review the reading assignments and practical exercises with the trainee.

D. **Readings:**

V. **Shoe Manufacturing**

A. **Objective:** The trainee will learn methods of footwear manufacturing.

B. **Practical exercises:**

1. Using a selection of footwear, describe the methods of manufacture.

2. Discuss the implications for identification and individualization based on

   a. the method of manufacture

   b. footwear design, fashion, and styles.

C. **Evaluation of Trainee Progress**

1. The trainer will review the reading assignments and practical exercises with the trainee.

D. **Readings:**

VI. Tires: Tread & Sidewall Design

A. **Objective:** The trainee will learn the significance of tread patterns, sidewall information, tire noise treatment, and tread wear indicators.

B. **Practical exercises:**

1. The trainer will provide the trainee with tires and tire imprints/impressions for examination. The trainee will complete the following practical exercises.

   a. Examine the tire(s) and describe the following features:

      i. tire construction and type
      ii. tread design
      iii. tread wear indicators
      iv. sidewall information including size, brand, mold identifier, & serial number
      v. noise treatment
      vi. sipes

   b. Examine the tire imprints/impressions and describe the following features:

      i. tread design
      ii. tread wear indicators
      iii. noise treatment
      iv. sipes
      v. manufacturer identification

C. **Evaluation of Trainee Progress**

1. The trainer will review the reading assignments and practical exercises with the trainee.

D. **Readings:**

VII. Tires: Wear Patterns
A. **Objective:** The trainee will learn the significance of tread wear patterns.

B. **Practical exercises:**
   1. The trainer will provide the trainee with tires and vehicles for examination. The trainee will complete the following practical exercises.
      a. Make vehicle measurements of the wheelbase and stance.
      b. Have the vehicle make left, right, and U-turns. Do this with the vehicle traveling in both a forward and rearward direction.
         i. Correlate the tire tracks with the direction of travel and the position of the wheels on the vehicle.
         ii. Measure the turning radius.
      c. Identify elements of vehicle suspension that affect tire wear.
      d. Survey vehicles for the following information.
         i. tire brand, size, model, type, and tread design
         ii. variation with position on vehicle
         iii. degree of wear with position on vehicle
         iv. variation with make, model and age of vehicle.

C. **Evaluation of Trainee Progress**
   1. The trainer will review the reading assignments and practical exercises with the trainee.

D. **Readings:**

VIII. **Tires: Tire Construction & Manufacturing**

A. **Objective:** The trainee will learn about tire construction, tire design, and tire manufacturing.

B. **Practical exercises:**
   1. Visit a tire manufacturing or retreading facility. (Note: A video may substitute for this visit.)
   2. Examine a tire mold and describe
      a. how the mold is designed and produced
      b. how a tire is manufactured
c. class, subclass and individual characteristics that may be produced in manufacturing a tire.

C. **Evaluation of Trainee Progress**

1. The trainer will review the reading assignments and practical exercises with the trainee.

D. **Readings:**

IX. **Producing Test Imprints and Impressions**

A. **Objective:** The trainee will learn about the examination of footwear preparatory to producing examination-quality test imprints and impressions

B. **Practical exercises:**

1. Document and conduct a preliminary examination of footwear, including
   a. description, brand, model, etc.
   b. blood and trace evidence
   c. damage
   d. Class and potential individual characteristics of outsole

2. Produce footwear test imprints or impressions by various means, including:
   a. Ink
   b. Dusting with fingerprint powder
      i. Adhesive lifting paper
      ii. Roller transport clean-up film (transparent)
   c. Photograph as needed.

3. Produce tire test imprints or impressions

4. Describe the advantages and disadvantages of the various methods of producing exemplar imprints/impressions.

5. Explain criteria for selection of the method.

C. **Evaluation of Trainee Progress**

1. The trainer will review the reading assignments and practical exercises with the trainee.
D. Readings:

X. Investigative "No Suspect" Information

A. Objective: The trainee will learn about the possible investigative information that can be gleaned from shoe imprint/impression evidence.

B. Practical exercises:

1. Study mock crime scene scenarios and develop investigative information, such as
   a. size, brand, and model of suspect’s shoes
   b. actions of individuals as revealed by their footwear patterns.
   c. possible tire brand and model.

2. Study the use of:
   a. footwear forensic databases (including online references, Foster + Freeman's SICAR, etc.)
   b. footwear manufacturers’ resources (printed or electronic).

C. Evaluation of Trainee Progress

1. The trainer will review the reading assignments and practical exercises with the trainee.

D. Readings:

5. “The True Story of Shoe Sizes,” The Sterling Last Corporation, 43-05 Tenth St., Long Island City, NY 11101.

XI. Comparison of Questioned Imprint/Impression to Known (Suspect) Impression

A. Objective: The trainee will learn how to compare questioned footwear/tire imprints/impressions to known (suspect) shoes/tires for the purpose of source attribution.

B. Practical exercises:

1. Make a comparison of partial or complete footwear imprints/impressions to suspect shoes.

2. Identify class and individual elements of the imprints/impressions.

3. Discuss the following with your trainer:
   a. criteria for identification
   b. criteria for recognizing individualizing elements (randomly acquired characteristics)
   c. relation of footwear manufacturing method to class, subclass, and individual characteristics of the sole
   d. weight for class or subclass identifications.

4. Study tire imprints/impressions from the mock crime scene.

5. Compare questioned tire imprints/impressions to known ("suspect") tires.
   a. Identify class and individual characteristics.

6. Discuss the following comparison process flowchart for tire examination with your trainer.
C. **Evaluation of Trainee Progress**

1. The trainer will review the reading assignments and practical exercises with the trainee.

D. **Readings:**

XII. Court and the Footwear Expert

A. **Objective:** The trainee will be able to competently present footwear and tire evidence in court.

B. **Practical exercises:**

1. Discuss criminal and civil law procedures with your trainer.

2. Prepare a presentation for a mock court exercise based on the report and notes from the competency test.

C. **Evaluation of Trainee Progress**

1. The trainer will review the trainee's performance in the mock court exercise.

D. **Readings:**

END OF DOCUMENT
I. Policy
   This manual covers the policies and procedures specific to the examination of solids, powders, and liquids for the presence of controlled substances.

   A. Terminology
      1. The verbs "shall", "must", and "will" indicate mandatory requirements, while "should" is used to denote compelling or recommended practices and "may" is used in the permissive sense.

   B. Scope of Examinations
      1. Analysis of solids (e.g. powders) and liquids for the presence of controlled substances. Quantitative analysis or purity checks are not performed on solid dosage cases.
      2. The laboratory does not analyze solids or liquids in cases related to Clandestine manufacture of controlled substances or their precursors.
         a. Such evidence may be tested for the presence of a controlled substance only.

   C. Presumptive Tests
      1. See Monographs as well as "Suggested Tests" in DRG.34 for more information on color tests for specific analytes.

   D. Confirmatory Tests
      1. See Monographs as well as "Suggested Tests" in DRG.34 for more information on confirmatory analysis for specific analytes. The titles of the Monographs are:
         a. Marijuana (MONO.MAR)
         b. Phenethylamines (MONO.PHEN)
         c. Phenethylamine Analogs (MONO.ANALOGS)
         d. Caines (MONO.COC)
         e. Benzodiazepines (MONO.BEN)
         f. LSD (MONO.LSD)
         g. PCP and Dissociative Anesthetics (MONO.PCP)
         h. Tryptamines (MONO.TRY)
         i. Steroids (MONO.STE)
         j. GHB (MONO.GHB)
         k. Opiates (MONO.OPI)
         l. Barbiturates (MONO.BAR)

   E. Test Methods
      1. The Controlled Substance Unit will use appropriate methods and procedures for all tests within its scope (DRG.34). These include:
         a. sampling (DRG.33)
         b. handling (DRG.09)
         c. storage (DRG.09)
d. preparation of items to be tested (DRG.34)
e. where appropriate an estimation of uncertainty as well as statistical techniques for analysis of test data (DRG.41 & DRG.42). (ISO/IEC 17025:2005 5.4.1)

2. The Controlled Substance Unit shall have instructions on the use and operation of all relevant equipment, handling and preparation of items for testing, see: DRG.43, DRG.44, DRG.45, DRG.46, DRG.47, DRG.48, DRG.49, DRG.50, DRG.51, DRG.52, DRG.53, DRG.54, DRG.55, DRG.56, DRG.25, DRG.18, DRG.28, DRG.29 and DRG.09. (ISO/IEC 17025:2005 5.4.1)

3. All instructions, standards, manuals and reference data relevant to the work of the Controlled Substance Unit shall be kept up to date and made readily available to personnel through the use of this Unit Manual. (ISO/IEC 17025:2005 5.4.1)

4. All methods shall be documented and the documents readily available for review by laboratory personnel through PowerDMS (FSD.12). (Supplemental 5.4.1.1)

5. Deviation from test methods shall occur only if the deviation has been documented, technically justified and authorized. (ISO/IEC 17025:2005 5.4.1)

F. Customer Communication

1. The laboratory uses a DAT (Drugs Alcohol and Toxicology) Handbook to communicate with the clients regarding the service offered, the equipment used and the opinions, conclusions and interpretations drawn based on results (ISO/IEC 17025:2005 4.7).

   a. The DAT handbook by itself or in combination with inter-agency agreements serves as inter-agency contract for service (ISO/IEC 17025:2005 4.4).

END OF DOCUMENT
I. Policy: Due to the higher probability of theft and/or tampering in narcotics cases than in other types of cases, stringent controls are necessary in the handling of narcotics evidence within the Drug Unit.

A. Laboratory Security

1. The Division Manual has written procedures for building security. (ISO/IEC 17025:2005 5.3.4, Supplemental 5.3.4.1)

2. See Division Manual polices on security: FSD.32.

B. Drug Unit Security

1. Drug evidence must be stored and examined only in those areas of the laboratory with restricted access to non-laboratory persons and are protected by intrusion alarms when the laboratory is vacant. (Supplemental 5.3.4.1 a, b, e, f)

2. To the extent possible, drug evidence should be kept in the drug examination room or evidence storeroom until returned to the submitting agency. (Supplemental 5.3.4.1 f, 5.8.4.1)

3. Anytime the Muir facility is vacant, the doors must be closed and locked and the alarms engaged. (Supplemental 5.3.4.1 b, c, e, f)

4. Keys to the secured areas are limited (Supplemental 5.3.4.1 d, 5.8.4.1). The secured areas in the controlled substance unit are the doors to the controlled substance unit and the lock boxes at each drug station. The keys for the lock boxes are maintained:
   a. Under the personal control of the Analyst(s) responsible for the case, and
   b. A duplicate key in a locked key box accessible to the Muir administration.

C. Personnel Security

1. Only Division personnel who have successfully passed an extensive background investigation and/or polygraph examination are permitted to handle drug evidence or reference materials (Drug Standards).

2. All other persons, including laboratory visitors, are permitted in the area of drug evidence or reference materials only when escorted by a Division member. (Supplemental 5.3.4.1 a)
3. All Division members must avoid discussing with individuals outside the Division the nature, quantity, and location of drugs which are present in the Division.

D. Drug Reference Materials Storage

1. Drug reference materials are to be kept in the secured designated storage/or refrigerator. Access to drug reference materials shall be limited to designated personnel. (ISO/IEC 17025:2005 5.6.3.4)

END OF DOCUMENT
I. Policy: A computerized inventory of laboratory drug reference materials (Drug Standards) is maintained. All controlled and prescription drugs are visually inventoried quarterly and weighed once in a calendar year. *(ISO/IEC 17025:2005 5.6.3.4)*

A. Description of Inventory

1. An alphabetical listing of all controlled, prescription and over the counter drug reference materials is maintained in a computer database.
2. The list is in an access database named "DRUG INVENTORY".
3. Current copies of the inventory are kept in the Chemical Storage Room and by the Manager of the Drug, Alcohol and Toxicology Section.
4. The inventory contains the generic name of the drug, the weight (number if in dosage form or volume if in liquid form) of the drug, inventory/vial number, and a code designating its location.

B. Quarterly Inventory

1. Quarterly, a staff member designated by the Manager of the Drug, Alcohol and Toxicology Section will visually inventory the drug reference materials.
2. The staff member will locate each item on the inventory and will verify the presence of each controlled and prescription drug. This will be compared with the current inventory list.
3. The Manager must be notified immediately of any missing drugs.

C. Yearly Inventory

1. Yearly, a staff member designated by the Manager of the Drug, Alcohol and Toxicology Section will inventory all of the drug reference materials.
2. The staff member will locate each item on the inventory and weigh, count, or measure all of the controlled drugs.
3. The changed amounts are recorded for updating the inventory. *(DRGF.10)* should be used to document drugs used for casework or training purposes.
4. Any discrepancies must be reported immediately to the Manager.

D. Updating the Inventory
1. The inventory will be updated routinely with the new amounts of each drug reference material and after each yearly inventory.

2. A new inventory listing will be created after the yearly inventory.

3. It is recommended to log any amount used on the **DRGF.10**.

4. However, when larger amounts are consumed, more than 100 milligrams, or released for such things as training or research, the date and amount must be recorded and initialed. This can be done on the **DRGF.10** in the Chemical Storage Room or at an analyst's workbench by the person consuming or releasing the drug.

5. When drug reference materials are added, the person maintaining the database must enter the reference material, assign a number, create a barcode, date, amount, and location on the inventory list in the Drug Database.

**E. Discrepancies in Inventory**

1. All discrepancies reported to the Manager, in connection with the quarterly or yearly inventory will be immediately investigated by him/her to determine if the discrepancy is due to an oversight or error.

2. If not, the Chief will be notified immediately. He/she will determine what, if any, investigation will be pursued.

3. If any controlled substances have been lost or stolen, the Manager must complete a "Report of Theft or Loss of Controlled Substances" form (DEA form 106) in triplicate and file it with the Drug Enforcement Administration Office in San Francisco.

**F. Inventory Records**

1. Inventories from previous years will be retained in a file by the Manager for a period of at least three years after which they may be discarded.

END OF DOCUMENT
I. Policy: Division personnel will comply with Drug Enforcement Administration (DEA) regulations regarding the purchase, disposal and records associated with controlled substances.

A. Introduction

1. The purchase of drugs, which are federally scheduled by the Controlled Substances Act, is restricted to persons and agencies registered with the Drug Enforcement Administration. The Division is registered as an analytical laboratory and must meet certain associated requirements to retain the registration status.

B. Registration Requirements

1. Prior to initial registration with the Drug Enforcement Administration (DEA), the site to be registered is inspected by a DEA agent to insure that security is adequate. The Division's security requirements are described in the Division Manual, and must be followed to ensure continued registration. Should the laboratory relocate, it must be re-inspected.

2. The registration must be renewed yearly and is effective until August 31 each year. The application for renewal is received in July each year. The Manager of the Drugs, Alcohol and Toxicology Section will renew the registration electronically or prepare the renewal form and return the renewal form to the DEA.

C. Ordering Controlled Substances

1. In order to purchase controlled substances, the vendor must be supplied with the laboratory's DEA Registration Number. Requisitions for Schedule I or II Controlled Substances must also be accompanied by a U.S. Official order Form (DEA form 222). Instructions for completing the form are listed on the back of the form.

2. DEA order forms are numbered and must be retained in a secure location. Order forms with errors must be marked "VOID" and retained. The Purchaser's copy of those forms sent to a vendor, along with the voided forms, must be retained indefinitely. An application for additional DEA order forms can be requested online and may only be requested by the Manager, as needed.
3. Ordering of controlled substances will be handled by the Manager. All DEA order forms must be signed by the designated signature.

D. Receipt of Controlled Substances

1. Any Division staff member checking in a Controlled Substances order must date and initial the individual containers and date and sign the packing list. A copy of the packing list is to be retained electronically.

2. The receipt of Controlled Substances will be recorded electronically in the Laboratory database.

II. Policy: Laboratory personnel will follow procedures for the selection, ordering, verification and storage of supplies. See FSD.30.

A. Ordering Supplies-Putting Supplies on the List to be Ordered

1. General laboratory consumables and supplies may be placed on the order list by any member of the laboratory staff. These consumables and supplies do not affect the test result.

2. The following are some examples of consumables that do not affect the test results:
   a. Gloves
   b. Glass or plastic transfer pipettes
   c. Vials, caps, inserts
   d. Shell vials
   e. Weigh paper
   f. Spot plates
   g. Bulbs
   h. Glassware

3. Supplies which may affect the test result (see below for some examples) should be placed on the order list by personnel within the unit in which the supplies are to be used. The following is a list of supplies that may affect the test results in Controlled Substance Unit:
   a. Reference Materials (Drug Standards)
   b. Parts for the GC/MS. These may be ordered based on part information in the instrument manual(s).
   c. Parts for the FTIR. These may be ordered based part information in the instrument manual(s).
   d. Balances
   e. Reference Standards (check weights for use with the balances)

4. The following is a list of services that affect the test result in Controlled Substance Unit. The suppliers of these services must be evaluated yearly and the evaluation will be documented:
   a. Calibration of balances
5. The "type" or "grade" of chemicals for use in controlled substance analysis is not specified in the procedure as any type or grade of chemical is acceptable.
   a. The chemicals used to make reagents are evaluated through the verification process of the reagent
   b. The chemicals (solvents) used for analysis are evaluated (for contamination) through the use of blanks before each sample

6. Supplies may be placed on the order list by any lab staff member and verified by a qualified analyst.

B. Approval of Orders
   1. Any lab staff member or support staff may order supplies from the vendor. The supplies on the "Supply Order List" are inputted into a computer database. The list(s) of supplies to be ordered is printed out (typically sorted by vendor).
   2. The verified list(s) of supplies to be ordered are then given to a Manager for approval.

C. Ordering Supplies from the Vendor
   1. After the list(s) of supplies to be ordered have been approved, any lab staff member or support staff may order supplies from the vendor by phone/e-mail. The orders maybe placed:
      a. using an existing open Purchase Order for vendors or
      b. using a requisition form or
      c. using the County credit card held by the Account Clerk.

D. Receiving Supplies
   1. Supplies that affect the quality of tests are not used until they have been inspected or verified as being the supply that was ordered.
   2. When the consumables or supplies are received by the laboratory, the supplies are unpacked and verified by:
      a. Using the database generated list of supplies to be ordered (or equivalent) and checking against the supplies received (labels on supplies)
      b. The supplies received are also checked against the shipping receipt or packing slip.
      c. The person checking the supplies against the shipping receipt will initial the shipping receipt. This paperwork goes to Account Clerk of the Sheriff's Department.
      d. The information from the database generated list of supplies to be ordered (or equivalent) is entered into the supply ordering database to ensure what was ordered is what was received.
      e. There is a received/verified date and place to indicate who is entering the information (by initials)
3. The supplies are then put away in a storage location.

4. General laboratory consumables and supplies are stored in the supply room or within the units of the laboratory. Any special storage requirements (refrigeration, storage in flammable, corrosive cabinets, etc.) will be adhered to.

5. Reagents and supplies will be re-evaluated on an on-going basis through the use of controls and intermediate checks.

6. Supplies required for specific instrumentation, chemicals required for certain procedures or supplies that are specifically listed in the method or procedure being used should be given to the lab staff member who ordered that supply item.

7. Reference materials are checked to ensure that the proper traceability paperwork accompanies the item or the traceability paperwork is retrieved from the vendor electronically. Reference materials (standards) are stored according to the storage recommendations on the package.
   a. The traceability paperwork Certificates of Analysis or other verification paperwork are maintained in the DRGF.09.
   b. Consumables provided by the manufacturer of the equipment being used - Manufacturer's consumables quality documentation is needed to ensure the quality of product is adequate for the testing being performed.
   c. Once a product is evaluated and approved for use, for example through validation or as supplied for use with an instrument, it will be ready for use in casework and may be ordered as needed.

8. Drug reference materials are entered into the drug inventory database upon receipt and verification. Drug reference materials will not be used for casework until verified. See the section of the DRG.12 for more information on verification of drug reference materials.

9. The received supplies are also entered electronically into the ordering database to verify that the supply that was ordered is the same as the supply that was received.

E. Discrepancies

1. If there is any discrepancy between the supply ordered and the supply received, the person ordering supplies will notify the vendor of the discrepancy and the supply will not be used by the laboratory. The supply will be returned and exchanged for the proper supply.

2. If there are any problems exchanging the supply for the correct item, the Forensic Manager or Supervisor will be made aware of the problem.

3. If the supply ordered is found to be defective or does not perform as expected it will not be used for casework.

4. Actions: Taking any actions arising from evaluations, monitoring of performance, and re-evaluations of the external providers. Actions may include ensuring the correct services or supplies are received, issues are resolved, or monitoring that services and supplies meet the needs of the unit.

F. Sole Source Vendors

1. Sole Source Vendors may be vendors that supply the lab with supply items that another vendor cannot readily supply. This may be because procedures were
validated with items specific to a vendor (eg. immunoassay plates). The Department Account Clerk maintains a justification for sole source vendors.

2. For the Controlled Substance Unit, a reference material used for confirmation is considered a supply that affects the quality of a test.

3. The laboratory chooses suppliers of reference materials by a number of factors including (but not limited to) price, ease of ordering, vendors with whom we have open purchase orders.
   a. The vendors commonly used to order drug reference materials are located in the supply ordering database
   b. All reference materials are verified before use in casework and the verification is documented. See DRG.12.

4. Vendors that provide a service that may affect the test result are:
   a. Rice Lake Weighing Systems or equivalent for balance, pipette, diluter, titrator calibration.
      i. Calibration services provided from an ISO 17025 vendor - Certificate of Calibration is needed for evaluation and documentation when calibration occurs

5. The Unit is responsible for the evaluation, selection and monitoring of performance, and re-evaluation of external providers.
   a. Criteria for evaluation, selection, monitoring of performance, and re-evaluation of the external providers. For example:
      i. Checking a scope document to ensure the calibration being requested is within the scope of the vendor
      ii. Checking an accreditation certificate to ensure that accreditation has not lapsed
      iii. Checking that quality controls or standards meet the performance criteria of the equipment or method
      iv. Ensuring that a certificate is checked after the expiration date before ordering additional supplies or service

END OF DOCUMENT
I. Policy: The following is a list of drugs that can be identified by the laboratory. The laboratory is not limited in scope to this list and has the capacity to analyze other drugs provided suitable standards are available. The laboratory may limit identification to the primary controlled substance if a sample contains breakdown products or secondary related controlled substances.

A. PHENETHYLAMINES
   1. Amphetamine
   2. Benzphetamine
   3. B-Phenethylamine
   4. Ethylamphetamine
   5. Mephentermine
   6. Methamphetamine
   7. Methylphenidate
   8. Phendimetrazine
   9. Phenmetrazine
   10. Phentermine

B. OPIATES
   1. 6-Acetylcodine
   2. 6-Monoacetylmorphine
   3. Apomorphine
   4. Butorphanol
   5. Codeine
   6. Dihydrocodeine
   7. Ethylmorphine
   8. Fentanyl
9. Heroin
10. Hydrocodone (Dihydrocodeinone)
11. Hydromorphone
12. Meperidine
13. Methadone
14. Morphine
15. Nalorphine
16. Norcodeine
17. Normorphine
18. Opium
19. Oxycodone
20. Oxymorphone
21. Papaverine
22. Propoxyphene
23. Thebaine

C. CAINES
   1. Benzocaine
   2. Benzoylecgonine
   3. Cocaine Base
   4. Cocaine Salt
   5. Ecgonine
   6. Lidocaine
   7. Mepivacaine
   8. Norcocaine
   9. Piperocaine
  10. Procaine
  11. Tetracaine

D. MARIJUANA
   1. Cannabidiol
   2. Cannabinol
   3. Marijuana Plants
   4. Tetrahydrocannabinol (THC)
E. DISSOCIATIVE ANESTHETICS
   1. Ketamine
   2. Phencyclidine (PCP) phenylcycohexylpiperidine
   3. Piperidinocyclohexanecarbonitrile (PCC)

F. HALLUCINOGENS
   1. +/-2,5-Dimethoxy-4-bromoamphetamine (2C-B, Nexus)
   2. +/-2,5-Dimethoxyphenyl-2-aminopropane
   3. 2,5-Dimethoxy-4-iodoamphetamine (DOI)
   4. 2,5-Dimethoxy-4-n-propylphenethylamine (2C-T-7)
   5. 3,4-methylenedioxyamphetamine (MDA)
   6. 3,4-methylenedioxyethylamphetamine (MDE)
   7. 3,4-methylenedioxymethamphetamine (MDMA)
   8. 4,4-dimethoxytrityl-chloride
   9. 4-chloro-2,5-dimethoxyamphetamine
   10. 4-methyl-2,5-dimethoxyamphetamine (DOM)
   11. 5-Methoxy-N,N-dimethyltryptamine
   12. Bufotenine
   13. Diethyltryptamine (DET)
   14. Dimethylamphetamine
   15. Dimethyltryptamine (DMT)
   16. Harmaline
   17. Harmine
   18. LAMPA
   19. Lysergic Acid
   20. Lysergic Acid Diethylamide (LSD)
   21. Mescaline
   22. Methoxyamphetamine
   23. Methyltryptamine
   24. n,n-Diethyltryptamine
   25. n,n-diisopropyl-5-methoxytryptamine (FOXY)
   26. N-Acetylmescaline
   27. Peyote
28. P-methoxyamphetamine (PMA)
29. Psilocin

G. BARBITURATES
1. Allobarbital
2. Amobarbital
3. Aprobarbital
4. Barbital
5. Butabarbital
6. Butalbital
7. Hexobarbital
8. Mephobarbital
9. Methabital
10. Pentobarbital
11. Phenobarbital
12. Secobarbital
13. Thiopental
14. Other barbituric acid derivatives

H. BENZODIAZEPINES
1. Alprazolam
2. Bromazepam
3. Chlorazepate
4. Chlordiazepoxide
5. Clobazam
6. Clonazepam
7. Desalkylflurazepam
8. Diazepam
9. Estazolam
10. Flunitrazepam
11. Flurazepam
12. Halazepam
13. Lorazepam
14. Medazepam
15. Midazolam
16. Nitrazepam
17. Nordiazepam
18. Oxazepam
19. Prazepam
20. Temazepam

I. STEROIDS
   1. 17a-Methandrostan-17B-OL-3-ONE (Mestaline)
   2. 17a-Methyltestosterone
   3. 17B-Dihydroandrosterone
   4. 19-Nortestosterone
   5. 19-Nortestosterone 17-deconate
   6. Androlone
   7. Androstenediol
   8. Androstenediol Dipropionate
   9. Androstenedione
  10. Androsterone
  11. Boldenone
  12. Boldenone Undecylenate
  13. Chlorotestosterone 17-acetate
  14. Dihydrotestosterone Benzoate
  15. Mesterolone
  16. Methandriol
  17. Methandrostenolone
  18. Methenolone
  19. Nandrolone
  20. Nandrolone Decanoate
  21. Nandrolone Phenpropionate
  22. Nandrolone Propionate
  23. Norethandrolone
  24. Normethandrolone
  25. Oxandrolone
26. Oxymetholone
27. Stanozolol
28. Testosterone
29. Testosterone 17B-Cypionate
30. Testosterone 17-Phenylpropionate
31. Testosterone Decanoate
32. Testosterone Enanthate
33. Testosterone Isocaproate
34. Testosterone Propionate
35. Trenbolone
36. Trenbolone Acetate
37. Trenbolone Enanthate

J. MISCELLANEOUS
1. 1,4-Butanediol
2. Chlora hydrate
3. Diethylpropion
4. Ethchlorvynol
5. Fenfluramine
6. Gamma Butyrolactone (GBL)
7. Gamma Hydroxybutyric Acid (GHB)
8. Glutethimide
9. Meprobamate
10. Methaqualone
11. Methylprylon
12. Pentazocine
13. Scopolamine
14. Valproic Acid
15. Zolpidem
16. Zaleplon

END OF DOCUMENT
I. Policy: The following is a list of some references available to analysts in the drug unit. Additional references may be found in the Drug Monographs. Additional literature may be found in the Muir Library. The list should not be considered inclusive of all references available. *(Supplemental 5.2.7)*

A. Controlled Substance References

3. Controlled Substance Monographs, Contra Costa County, Office of the Sheriff, Forensic Services Division.

4. CND Analytical Profiles

5. Instrumental Data for Drug Analysis, T. Mills & J. Roberson

7. Drug Identification Bible (any edition)

8. Physician's Desk Reference (any edition)

10. Amera-Chem RX-ID CD ROM (any edition)

END OF DOCUMENT
I. **Policy:** The following documents is the general information about the Controlled Substance Envelope (CSE) and Controlled Substance Report.

A. A Controlled Substance Envelope provided by the laboratory contains all the information necessary for a request for drug analysis.

1. If a CSE is not used, the following information is needed by the laboratory for controlled substances submissions:
   a. Person requesting the examination
   b. Requesting agency
   c. Agency case number
   d. Offense(s)
   e. Full name of all suspects
   f. Chain of custody
   g. List of item(s) being submitted (including item number, description and source)

2. The laboratory staff responsible for receiving the evidence is responsible for indicating on the request form that the evidence was received in a tape sealed condition.

3. The following information is desired:
   a. Telephone Number
   b. Badge Number
   c. Indication if a RUSH is needed and the reason
   d. If CHP, the arrest location
   e. If fingerprint analysis is also required
   f. Agency instructions to the laboratory

B. Reports for controlled substance analysis will adhere to Division policy. See FSD.43. For more information regarding the contents of the report and the annex to the report, refer to the reporting policy in the Controlled Substance Technical Unit Manual. See DRG.11.
END OF DOCUMENT
| Contra Costa County | REVISION DATE: |
| Office of the Sheriff | 10/31/2019 |
| FORENSIC SERVICES DIVISION | NUMBER: |
| Controlled Substances Technical | DRG.09 - Evidence |
| Unit Manual | Handling |

**RELATED ORDERS:** FSD.35 - Evidence Handling, DRG.33 - Case Examination Protocols & Sample Selection, FSD.38 - Evidence Itemization, FSD.31 - Subcontracting & Externally Directed Analysis

**APPROVED BY:** Joaquin Jimenez & Danielle Adams

**ANAB:** 7.4

**CHAPTER:** Evidence Handling

**SUBJECT:** Evidence Handling
I. Policy: The following guidelines for the preparation of examination records must be followed in all cases. Failure to do so will result in the report and examination records being returned to the analyst for correction. These guidelines represent the most common note taking requirements. See FSD.42 for more information.

A. The case record is considered to be the files containing administrative and examination documentation generated or received by a laboratory pertaining to a particular case. The case record consists of:

1. The report and case notes (examination documentation)
2. Any records of phone conversations or e-mail communication will be maintained as administrative documents
3. Discovery requests or referee analysis requests are maintained as administrative documents
4. The electronic chain of custody. The official chain of custody is maintained in the Laboratory Information Management System (LIMS). See FSD.35. The chain of custody at the time the case is submitted for review may be included in the case notes
5. A reference to the Lot # of standards used for confirmation will be included in the case notes. More information about the Lot # may be found in the Drug Verification Log (DRGF.09).
6. A reference to the reagents used in the case will be included in the case notes More information about the reliability of reagents is maintained in the Reagent Log
7. A reference to the equipment used in the case will be included in the case notes. The reliability of equipment used is maintained in their respective maintenance logs. The unique identifier for the Stereomicroscope used for confirmation of marijuana samples is not included in the case notes.
8. A reference to the instrumental operating parameters (method name) used in the case will be included in the case notes. The operating parameters for the GC/MS are located in the maintenance binder for each instrument. The operating parameters for the FTIR are located in the Controlled Substance Standard Operating Procedure
9. Communication on Business Record or Official Record for court is maintained electronically under case activities in the Laboratory Information Management System (LIMS)-see below

B. Examination Records

1. Examination records (notes) and observations, data and calculations shall be recorded at or near the time they are made and shall be identifiable to the specific task.

2. The date(s) of analysis will appear in the case notes. The technical records will identify on what date(s) each task was performed. (See FSD.42)

3. The records must be sufficiently detailed that in the absence of the analyst, another competent analyst or supervisor could evaluate what was done and interpret the data and would know the basis of the conclusions. The case notes and records shall be sufficiently detailed to facilitate an audit trail (the test being repeated under conditions as close as possible to the original) and shall include the identity of the personnel responsible for sample selection, performance of each test and checking of results.

4. Examination records shall be of a permanent nature in ink or computer generated. See DRG.38 for instructions on how to generate electronic notes.

5. Case notes will be single-sided on a page

6. The notes can be LIMS generated or handwritten. See DRG.38 for instructions on how to generate electronic notes.

7. The list of abbreviations found in DRG.07 can be used in note taking.

8. Refer to the Division Manual for policies regarding retention of case records. See FSD.44.

C. Business Records or Official Records

1. If an individual (other than the analyst on the report) interprets the findings including testifying concerning the documentation (eg. Business Record or Official Record), that individual will document the review of the examination documentation in LIMS.

2. The use of the LIMS activity "Business/Official Record" means that the report and notes were reviewed by the individual. If time is spent but a review is not completed, an alternate activity can be used (ie. Court prep).
   a. For case related (lab number related) business records or official records the activity should be related to the request.
   b. For non-case related activity, click on the "activity button"

3. LIMS Instructions:
   a. Under the request tab, select the request
   b. Right click and select "activity"
   c. Click the green "+" button
   d. Choose the appropriate activity (Business/Official Record or court prep)
e. Add the time spent and the notes should document why a business or official record was done

D. For examined items, the following must appear in the case notes along with data and results:

1. **Weight:** The net weight of all material(s) (eg. powder, crystalline material or loose plant materials) examined.
   a. The estimated weight or gross weight of material(s) (eg. powder, crystalline material, or loose plant material) not examined.
   b. Calculations for any weight estimates or manner in which the estimated weight was determined must be noted.
   c. Total estimated weights should be reported for possession for sale cases.

2. **Dosage Units:** The number or estimated number of dosage units received.

3. **Estimated Volume:** The estimated volume of any liquid samples.

4. The manner or technique used to measure or estimate the volume should be noted.

5. **Verifications:** If any examination verifications are performed by an competency tested analyst, for example verification of a new analyst's first 50 marijuana cases, the initials of the verifier and date will be recorded in the case notes in LIMS. The verifier's initials indicate that the finding was agreed upon.

6. **Discrepancies:** Any differences between the number of units or items in the evidence description and the envelope contents.
   a. The name or initials of the analyst verifying the discrepancy and the date will be recorded in the analyst's notes.
   b. The information (description of evidence) contained in the report being reviewed by the Agency will be considered as notification of any discrepancies.
c. A photograph should be taken when possible to illustrate the discrepancy.

d. The checkbox in the “Controlled Substance Analysis” request extended data form for “Inventory Discrepancy” will be checked to identify any request containing a discrepancy. Marking the checkbox for a discrepancy will cause "An inventory discrepancy was noted" to appear in the analyst's notes.

e. The technical and administrative review conducted by a Supervisor or Manager will be considered as notification to a Supervisor/Manager of any discrepancies. If the Supervisor or Manager is not the technical reviewer, they must be notified (eg. email, given copy of notes, etc.)

7. **Packaging**: A notation regarding any unusual occurrences such as leaking containers, spilled evidence, seals that appear to have been broken, etc.

   a. An explanation and date of any reopening and resealing of evidence items or the evidence envelope.

   b. If the item(s) were repackaged differently than how they were received.

8. **Sample Consumption**: A notation in the notes and report if the sample was completely consumed during analysis, such that re-analysis is not possible.

   a. Refer to the Division Manual policy on Sample Preservation.

   b. The notification to the Agency will be a statement on the report reflecting consumption of evidence during analysis.

9. **Referee Analysis**: A notation regarding any item sent for analysis to a referee laboratory

   a. For instructions on splitting, packaging, and sending a sample to a referee laboratory see [DRG.39](#).

10. **Similar in Appearance (Units)**: If there are multiple units within an item and a percentage is selected for examination, a notation should be included in the notes indicating the units were packaged and/or similar in appearance. Opinions regarding the identification of untested items will not be offered.

11. **Similar in Appearance (Items)**: If an item is not examined because it is similar to an item already examined, a notation should be included in the notes and report indicating the item(s) were packaged and/or similar in appearance. Opinions regarding the identification of untested items will not be offered.

12. **Traceability** information including, but not limited to:

   a. The balance used

   b. The vial # of the reference material (standard) used

   c. The reference for pharmaceutical presumptive identification

   d. The library used

13. **Technical/Administrative Review Corrections**:

   a. Technical review corrections: All corrections will be recorded in LIMS in the Request #, within the Notes: Reviewer field

      i. Identify any corrections and include the reason for the correction
ii. Record the date and technical reviewer's initials

iii. The analyst will enter when the correction was completed with their initials and date.

b. Administrative review corrections: All corrections will be recorded in LIMS in the Request #, within the Notes: Reviewer field
   i. Identify any corrections
   ii. Record the date and technical reviewer's initials
   iii. It is recommended that the analyst enter when the correction was completed with their initials and date.

E. Page Identification
   1. All note pages shall have the laboratory number, handwritten or computer generated initials of the examiner and the page number on the upper right hand corner of the page.
   2. The first and last page shall have the total number of pages.

F. Corrections
   1. Handwritten corrections must be made using a single line strikeout. The person making the correction must initial nearby.
      a. Pre-electronic notes: If the correction or addition is made after the draft complete date and when the notes package is submitted for technical review the person making the change must initial and date nearby.
      b. Electronic notes: If a correction or addition needs to be made after the draft complete, the notes must be un-draft complete, corrected and re-draft complete. An amendment must be opened and completed to make corrections to the notes after administrative review.
   2. An electronic audit trail is maintained to view changes made electronically after a case has been draft complete.

G. Miscellaneous Information
   1. The following miscellaneous information may be attached to the case documentation electronically:
      a. Telephone logs
      b. Special procedures
      c. Drawings (photocopies are acceptable)
      d. Pictures or information from reference sources (CDs or websites)
      e. Photographs
   2. Administrative documentation
      a. Pre-Electronic : Will be uniquely identified by the laboratory with the laboratory number. Refer to the Division Policy on Case Records.
      b. Electronic : Will be imaged into all relevant requests as ADM.XX.
H. Disposition of Evidence

1. The evidence disposition is included on the annex of the report. Evidence being returned to the submitting agency or being forwarded to Property is considered routine and those transactions are documented in LIMS.

2. Any evidence that is not immediately returned to the agency will be noted on the Report as a Report Comment.

END OF DOCUMENT
I. Policy:  Reports will be written in accordance with the following guidelines.

A. Report Writing

1. Controlled substance analysis reports are to be prepared by the analyst at or near the time of completion of the analysis.

2. A notation that the sample has been consumed during analysis should appear in the notes and on the report. See the Division Manual policy on Sample Preservation, FSD.35.

3. If an item is not examined because it is similar to an item already examined, a notation should be included in the notes and report indicating the item(s) were packaged and/or similar in appearance.

4. The results of each test or series of tests carried out by the laboratory shall be reported accurately, clearly, unambiguously and objectively, and in accordance with any specific instructions in the test methods. The results shall include all the information requested by the customer and necessary for their interpretation of the test results and all information required by the method used.

5. The results will be reported in a laboratory report of examination and includes the information required by the customer necessary for their interpretation of the test result (the results of analysis, schedule and weight of items examined) as well as the method used (analytical techniques). See DRG.38 for instructions on how to generate electronic reports.

a. If the request for analysis is cancelled, the Laboratory will issue a report indicating no work was performed. See DRG.38 for more information.

6. Reports will include information, unless otherwise indicated:

a. Title of report or "Report of Laboratory Examination"

b. Identity and location (address) of the testing laboratory

c. Unique case identifier (laboratory number) and clear identification of the end of the report
d. Name of the customer (submitting agency) the address of the customer is in the report annex.
   i. The address of the contracted agencies in Contra Costa County will be maintained by the Laboratory.
   ii. An *effort* will be made to obtain addresses for agencies that do not *routinely* use the services of the Drug, Alcohol, and Toxicology Section.

e. Method(s) used or analytical techniques employed is in the report annex.

f. Description of, condition of and unambiguous identification of submitted evidence. This is the item description accompanied by item number. The tape-sealed condition of the outer packaging is also included.

g. The date of request is included on the report. The date of receipt of evidence is in the report annex.

h. The date(s) of the examination will be included on the report. The analyst will enter the exam date(s), a date range if applicable, in the LIMS extended data field of the request.

i. The reference to the sample selection plan is in the report annex. The report states how many items are tested.

j. Results of analysis including units of measurement.

k. Routine disposition of evidence will be included in the report annex. Evidence will be returned to the agency unless otherwise noted.

l. Identity and signature (or electronic equivalent) of the author of the report and the reviewer. For Controlled Substance reports, the "approved by" signature refers to the individual who technically and administratively reviewed the case.

m. Clarity of how many units were tested and that the results reported only relate to items tested
   i. For multiple item cases: if items are not tested the report will indicate that the item was not tested
   ii. For multiple unit cases: if all units are not tested, a statement about the number of units tested will be included (For example: *Tested 1 of 9*)
   iii. For pill cases: if all pills are not tested, a statement about the number of pills examined will be included (For example: *One pill examined and found to contain the above result*)

7. In addition, reports shall, where necessary for the interpretation of test results, include the following, unless otherwise indicated:

   a. Any deviations in analytical techniques, will be included in the case notes

   b. Uncertainty of net drug weights, will be included in the report annex. A statement on the report will indicate that for any estimated weight, if uncertainty is required, the lab can perform further work. For more information see [DRG.42](#).
c. Opinions and interpretations. Results of drug analysis are conclusions. The report header will state "Examination Results and Conclusions".
   i. A qualifying statement about the opinion of an analyst regarding the similarity of items to one another "similar in appearance" based on the analyst's visual examination of the evidence will be in the report annex.

d. Additional information required by customer if necessary (eg. schedule of controlled substance identified)

8. In addition, test reports containing the results of sample selection shall include, where necessary, for the customer's interpretation of test results, include the following, unless otherwise indicated:
   a. The date of sample selection will be included in the case notes. The date(s) of analysis will be included on the report.
   b. Unambiguous identification of the item (item number)
   c. Location of sample selection or analysis is the laboratory, this in the report annex.
   d. The sampling plan is in the Controlled Substance Unit SOP.
   e. There are no environmental conditions that would affect sample selection, thus this is not applicable.
   f. Any significant deviations from the casework protocol or sample selection plan in the SOP will be authorized by the Supervisor or Manager and be noted in the case notes

9. In addition, test reports will contain the following:
   a. Date of report (Draft Complete date in LIMS)
   b. An association made of the item with its location.
      i. A qualifying statement about the association between the item and its reported location as coming from information provided by the agency will be in the report annex.
   c. If no definitive conclusions can be reached, the reason will be documented
   d. The author of the report will have conducted, participated in or observed the examination or testing

10. Laboratory personnel who issue findings, including writing reports and providing testimony, based on examination results documented and generated by another person will document the review of examination documentation in LIMS. See DRG.10 for a more detailed instruction.

11. The release of case report information as well as Verbal Results will be done according to Division Manual Policy. See FSD.43.

12. The electronic release of reports will be done through the Automated Regional Information Exchange System (ARIES) and in accordance with the Division Policy. See FSD.43.
13. The format of reports will be in conformance with the Division Manual policy. See FSD.43.

14. Amendments to reports will be in conformance with the Division Manual policy. See FSD.43 and QA.04.

END OF DOCUMENT
I. **Policy:** Reference Materials (Drug Standards) will be verified, labeled and stored in a manner to ensure the integrity of the standard.

A. Reference Material Collection

1. **Reference Material:** A reference material is a substance of known concentration and/or composition.

2. All reference materials received must be verified and the verification must be documented (DRGF.09). Some examples of verification include (ISO/IEC 17025:2005 5.6.3.2):
   a. Instrumental analysis such as GC/MS or FTIR analysis and comparison to a published spectrum or comparison to an existing verified reference material. Some examples of publications include but are not limited to:
      i. CND Analytical Profiles
      ii. Instrumental Data for Drug Analysis, T. Mills & J. Roberson
      iv. Peer reviewed published articles
      v. SWGDRG Mass Spectral Library
      vi. NIST Mass Spectral Library
   b. A Certified Reference Material (with accompanying certificate from a vendor accredited under ISO Guide 34)
   c. A NIST Reference Material

3. **Working Reference Material:** A working reference material is a substance transferred from the original packaging to a separate laboratory container. A working reference material should be prepared using a minimal amount of the reference material. Analysts should fill out DRGF.10 when consuming reference materials to make working reference materials. This will aid in conducting the Drug Inventory.

B. **Labeling**
1. All reference material containers must be labeled with the following information:
   a. Name of reference material (standard)
   b. Source
   c. Lot number
   d. Vial number (Required for tracking in the drug inventory)
   e. Initials of the person who received the reference material

2. All working reference material (standard) containers (typically GC vials) should be labeled with the following information:
   a. Name of reference material
   b. Vial number
   c. The initials and date of the person preparing the reference material
   d. The solvent and internal standard being used

C. Storage, Handling and Use (ISO/IEC 17025:2005 5.6.3.4)
   1. All reference materials will be stored, handled and used in a manner that prevents contamination, deterioration and protects their integrity. This includes:
      a. Storing reference materials according to the vendor instructions on the reference material label or certificate.
         i. Controlled, non-controlled, and prescription reference materials are stored in one or more of the following locations within the laboratory:
            1. The chemical storage room.
            2. A refrigerator within the drug unit.
         ii. Drug reference materials that are controlled, non-controlled, and prescription reference materials should **not** be kept at an analyst's workbench for extended periods. If it is necessary to keep a reference material for an extended period, even overnight, the Manager/Supervisor should be notified about the reference material being kept at the workbench along with the assigned drug inventory tracking number.
         iii. Working reference materials should be stored at the analyst's workbench, under a chemical hood, or in a refrigerator located within the laboratory.
            1. Access to the working reference materials is available to all technical staff within the Laboratory.
      b. Handling the reference material with care when removing it from its storage location and returning it to its designated location.
         i. Movement of reference materials within the laboratory is not considered transport.
      c. Using the reference material utilizing good lab practices to prevent against contamination and to protect the integrity of the reference material. This may
include:

i. Ensuring proper labeling as noted above.

ii. Abiding by any expiration dates on the reference material label or certificate, and not using the reference material or any solution made from that reference material past the expiration date.

   1. This includes ensuring the expiration date on the reference material label or certificate is transferred to any secondary bottle or solution made from that reference material. Or, if there is a laboratory assigned expiration date that is before the expiration date of the reference material, the laboratory assigned expiration date will be transferred to any secondary bottle or solution made from that reference material.

   iii. Following any safety warnings on the reference material label or certificate.

D. Intermediate Checks (ISO/IEC 17025:2005 5.6.3.3)

1. The reference materials run in the "performance standard" and monthly reference materials are checked each time they are run to ensure appropriate ions are present for identification by clicking on the peak on the "TOTAL ION CHROMATOGRAM" and evaluating the spectra data in the "ION SCAN".

   a. This is based on the frequency of use of these reference materials and the analyst's knowledge of the spectra.

2. Other reference materials run for casework are also evaluated each time they are run by evaluating the spectra data in the "ION SCAN". Analysts frequently use a library search to ensure major ions are present.

3. The ions are also evaluated when the report is technically reviewed. The retention time and spectral data for all reference materials used for confirmation are included in the case notes and evaluated.

E. Reference Standards (Balance Check Weights)

1. See DRG.18 for the program and procedure for calibration of check weights (reference standards). (ISO/IEC 17025:2005 5.6.3.1)

END OF DOCUMENT
I. Policy: Reagents will be prepared in accordance with recipes in the drug monographs and/or reagents binder. Effectiveness of reagents will be checked prior to use in casework.

A. The Reagent Log must be filled in with the appropriate information.
   1. A list of commonly used reagents and recipes can be found listed below.

B. Initial Reagent Verification
   1. Reagents are tested to verify they are working as expected when initially prepared and the check is documented. See DRGF.13.
      a. The reagent log will also indicate who prepared the reagent and who checked the reagent and the date checked
      b. Verification using a drug standard will include the vial number of the standard
      c. Verification by GCMS will include the instrument number

C. Reagent Retesting
   1. Reagents will be given a retest date 2 years from the date of preparation to ensure they continue to work as expected.
      a. After 2 years, the solution should be discarded or retested
      b. After a successful retest, the retest date can be extended for one year. The check will be recorded in the log.
         i. The check may be performed on the stock solution or a working solution
      c. If an issue arises prior to the next retest date, the solution will be checked or discarded. The check will be recorded in the log.
      d. If an issue arises with a working solution that has to be discarded, the stock solution should be checked to determine if it must also be discarded. The check will be recorded in the log.
   2. The lifespan of the Marquis reagent varies greatly and may be shorter than two years depending on storage conditions. See below for on-going checks of reagents.

D. On-going Checks of Reagents
1. Reagents are checked routinely with casework analysis by comparison of the reagent result to the analyte confirmed.
   a. The reagent results are evaluated by the analyst and technical reviewer.
   b. If issues arise, for example the reagent not giving the expected result for the analyte confirmed, the reagent should be checked against a standard and the check should be logged in the reagent log.

2. Webers must be prepared and used the same day. The analyst signing the report is the analyst who prepared the reagent; the preparation is not logged in the Reagent Log due to the short shelf life of the reagent. A positive confirmatory result is considered the check of the reliability of the reagent. If the confirmatory results are negative, the analyst will check the reagent with a standard, to ensure its reliability, and record that check in the case file.

E. Reagent Labeling

1. The reagent will be labeled, at minimum, with:
   a. The identity of the reagent
   b. The date when the reagent was prepared or a lot number
   c. The storage requirements, as applicable
      i. Chemicals will be stored in accordance with SAF.12 and manufacturing labeling recommendations
      ii. Reagents are stored in a fume hood
      iii. All reagents are stored at room temperature unless labeled otherwise
   d. Retest date

F. Reagent Recipes and Analytes Used for Verification

1. Refer to Table 1 for the analyte used for verification of the reliability of the reagent.
   a. Refer to the Reagent Recipe list below for reagent recipes and hazard information.

### Reagent Recipes

**Benedict's Solution**

**Compound(s) of Interest: Reducing Sugars**

**Primary Analyte for Verification: Glucose (dextrose)**

**Recipe:** Solution 1 or A:
- 0.865 g CuSO₄ (or 1.353 g CuSO₄ • 5 H₂O)
- 5 ml water

**Recipe:** Solution 2 or B:
- 8.65 g sodium citrate (or 9.858 sodium citrate dihydrate Na₃C₆H₅O₇ • 2H₂O)
- 5 g anhydrous Na₂CO₃
- 40 ml hot water
Benzaldehyde Internal Standard

**Compound(s) of Interest:** GC/MS internal standard for 1,4 butanediol  
**Primary Analyte for Verification:** GC/MS (correct ions present)

Benzaldehyde Internal Standard Recipe  
- 0.1 ml benzaldehyde  
- 10 ml chloroform

---

Chens Solution

**Compound(s) of Interest:** Ephedrine/Pseudoephedrine  
**Primary Analyte for Verification:** Ephedrine

**Recipe:** Solution 1 or A:  
- 1% CuSO$_4$ in water

---

**Recipe:** Solution 2 or B:  
- 1% Acetic Acid

---

**Recipe:** Solution 3 or C:  
- 8% NaOH

---

Cholesterol Internal Standard
**Compound(s) of Interest:** GC/MS internal standard for all steroids except for stanozolol

**Primary Analyte for Verification:** GC/MS (correct ions present)

Cholesterol Internal Standard Recipe
- 0.1 g cholesterol
- 2 ml methanol
- 3 ml chloroform

---

**1% w/w Cobalt Nitrate Solution**

**Compound(s) of Interest:** GHB

**Primary Analyte for Verification:** GHB

**Recipe:**
- 3.9 g cobaltous nitrate
- 500 mL methanol

---

**Cobalt Thiocyanate (COSCN) Solution**

**Compound(s) of Interest:** Cocaine

**Primary Analyte for Verification:** Cocaine Base

**Recipe:**
- 2% solution of cobalt thiocyanate in water

---

**Modified Cobalt Thiocyanate (M-COSCN) Solution**
Compound(s) of Interest: Cocaine  
Primary Analyte for Verification: Cocaine Salt

Recipe:
- 18 ml water
- 0.36 g cobalt thiocyanate
- 8 ml phosphoric acid
- 1 ml 10% platinum chloride
- Solution should be filtered.
- If solution is too orange, allow time for precipitate to form then filter again

Dille-Koppanyi (Koppanyl) Solution

Compound(s) of Interest: Barbiturates  
Primary Analyte for Verification: Secobarbital

Recipe: Solution 1 or A:
- 1% cobaltous acetate in absolute methanol

Recipe: Solution 2 or B:
- 1.5 mL isopropylamine
- 28.5 mL in absolute methanol

Duquenois-Levine Solution

Compound(s) of Interest: THC  
Primary Analyte for Verification: Marijuana or Delta-9-THC

Recipe:
- 0.5 ml acetaldehyde
- 50 ml ethanol
- 1 g vanillin

**Ferric Chloride Solution**

*Compound(s) of Interest: GHB*
*Primary Analyte for Verification: GHB*

**Recipe:**
- 5% solution in water

**Froehde Solution**

*Compound(s) of Interest: General*
*Primary Analyte for Verification: Heroin*

**Recipe:**
- 0.1 g molybdic acid
- *10 ml hot, concentrated sulfuric acid*
- *Heat acid on hotplate until powder dissolves*

**Liebermann's Solution**

*Compound(s) of Interest: Cathinones, Steroids, Miscellaneous*
*Primary Analyte for Verification: Methadone*

**Recipe:**
• 5 g sodium nitrite
• 50 mL sulfuric acid

Marquis Solution

Compound(s) of Interest: Phenethylamines and Opiates
Primary Analyte for Verification: Methamphetamine

Recipe:
• 10 ml sulfuric acid
• 8-10 drops 40% (approximately) formaldehyde
• note: solution slowly loses potency over 1-2 months

Mecke Solution

Compound(s) of Interest: Phenethylamines and Opiates
Primary Analyte for Verification: Heroin

Recipe:
• 0.25 g selenous acid
• 25 ml sulfuric acid

pDMBA (p-dimethylaminobenzaldehyde) Solution

Compound(s) of Interest: LSD, Psilocyn, Tryptamines
Primary Analyte for Verification: LSD or Psilocyn
Recipe:
- 0.1 g p-dimethylaminobenzaldehyde
- 18 ml ethanol
- 2 ml sulfuric acid

1.2 N potassium hydroxide (KOH)

Compound(s) of Interest: used for GHB analysis
Verification: check that pH is basic

Recipe:
6.732 g KOH, add water to a volume of 100 mL

Rothera Solution

Compound(s) of Interest: secondary amines
Primary Analyte for Verification: Methamphetamine
Rothera 2 may be verified alone with pH paper, pH >= 10

Recipe: Solution 1 or A:
- 5% sodium nitroferricyanide (aka nitroprusside) in water

Recipe: Solution 2 or B (saturated Sodium Carbonate):
- Saturated Sodium Carbonate solution in water
Recipe: Solution 3 or C:
  • 10 % acetaldehyde in water

n-Tricosane Solution

**Compound(s) of Interest:** GC/MS Internal Standard  
**Primary Analyte for Verification:** GC/MS (correct ions present)

Recipe:
  • 0.1 g n-tricosane  
  • 15 ml chloroform  
  • 9 ml methanol

Valerolactone Internal Standard

**Compound(s) of Interest:** GC/MS internal standard for GBL  
**Primary Analyte for Verification:** GC/MS (correct ions present)

Valerolactone Internal Standard Recipe
  • 0.1 ml valerolactone  
  • 10 ml water

Webers Solution

**Compound(s) of Interest:** Psilocyn  
**Primary Analyte for Verification:** Psilocyn

Recipe:
  • 1-2 heaping toothpicks of o-Dianisidine bis(diazotized) zinc double salt (CAS # 14263-94-6) AKA Fast Blue B Salt in...
• ~0.5 mL water
• Allow solids to settle out
• Use within a day

Zwikker Solution

Compound(s) of Interest: Barbiturates
Primary Analyte for Verification: Secobarbital

Recipe: Solution 1 or A:
• 0.5% copper sulfate in water

Recipe: Solution 2 or B:
• 5% pyridine in chloroform

10% Hydrochloric Acid (HCl) Solution

Compound(s) of Interest: used for Acid/Base Extraction
Verification: check that pH is acidic

Recipe: 10% solution of Hydrochloric Acid in water

END OF DOCUMENT
I. Policy: The technical review process addresses the appropriate use of analytical controls; correct interpretation based on analytical controls; and the consensus of results between the examiner and the reviewer. This process ensures the conclusions of the analyst's are reasonable, within the constraints of validated scientific knowledge and supported by examination documentation. See FSD.17.

A. Any significant differences in results by the reviewer must be resolved prior to issuing a final result and report.

   1. If a discrepancy is found, the report and notes along with a notation describing the discrepancy is returned to the analyst for correction.

B. Technical review shall be conducted by individuals having experience gained through training in the Controlled Substance Unit.

   1. Personnel who have successfully passed the competency test for controlled substances are minimally qualified to perform technical review in the controlled substance unit. However, based on the work load and experience of the analysts the Manager/Supervisor may choose to designate a specific Criminalist as Tech Reviewer in their absence.

      a. It is recommended that a currently proficiency-tested analyst perform the majority of the technical review of a newly competent drug analyst to ensure the most current practices and procedures are being implemented and reviewed.

      b. The duration or number of cases to be technically reviewed by a currently proficiency-tested analyst will be determined by the Supervisor/Manager.

   2. Documentation of personnel authorized to perform technical review will be documented on the Training authorization checklist.

   3. The individual technically reviewing the report will not be the person who authored the report.
4. The technical reviewer will consider the following scope, which include, but may not be limited to:
   a. Approved technical procedures used and documented, any deviations in analytical techniques will be included in the case notes. The color produced or reaction observed is documented for presumptive color tests in the case notes.
   b. Marijuana microscopic tests include a description of leaf characteristics.
   c. Accuracy of test reports: the data supports the results and/or conclusions in the test report. "No common controlled substance detected" supported by adequate screening tests which may include instrumental analysis (except for marijuana).
   d. Results are properly transferred from notes to report.
   e. Evidence weights calculated properly and appropriately stated (including units of measurement).
   f. Documentation of the use of verified reference material as well as blanks and internal standard as applicable. Appropriate extraction procedures (methods and solvents) for preparing samples for instrumental analysis were used.
   g. Documentation of the identity of equipment (except stereomicroscopes) used for analysis in the case notes.
   h. Instrumental charts and graphs are included and meet laboratory criteria for identification. GC/MS mass spectra, GC retention times or infrared spectra are compared to lab standard and match sufficiently.
   i. Controlled substance reported uses nomenclature listed in Health and Safety drug schedules. For some drugs, the laboratory may not be able to identify isomers (eg. Ephedrine/Pseudoephedrine and Propoxyphene/Dextropropoxyphene).
   j. Proper schedule listed for controlled substances.
   k. Significant figures will be consistent between the reported Total Net Weight or Total Estimated Weight and the analyzed unit weight(s) for each item.

5. The Technical Reviewer may use DRGF.11 encompassing the scope listed above.
   a. It is recommended that any newly competent analyst reference DRGF.11 prior to submitting cases for technical review (For example: cases with multiple items).
   b. It is recommended for any technical reviewer that is not currently proficiency tested to reference DRGF.11 upon reassignment to this task.

6. The Administrative review milestone in LIMS reflects the technical and administrative review of the case.
   a. The signature of the reviewer on the laboratory report designates approval.

II. Policy: The administrative review process addresses the case report package for format and content. The reviewer verifies the requested examination has been performed and the basis for the conclusions is supported in the notes. See FSD.18.
A. It is the responsibility of the analyst, not the Manager/Supervisor, to prepare and present a completed report package that complies with the Laboratory's policies and is free of errors.

1. It is recommended that any newly competent analyst reference DRGF.11 prior to submitting cases for administrative review.

2. It is recommended for any administrative reviewer that is not currently proficiency tested to reference DRGF.11 upon reassignment to this task.

B. All reports will be technically and administratively reviewed by a Manager/Supervisor or a person designated by the Manager/Supervisor.

C. The individual administratively reviewing the report will not be the person who authored the report.

1. Personnel who have successfully passed the competency test for controlled substances are minimally qualified to perform administrative review in the controlled substance unit. However, based on the work load and experience of the analysts the Manager/Supervisor may choose to designate a specific Criminalist as Admin Reviewer in their absence.

2. Documentation of personnel authorized to perform administrative review will be documented on the Training authorization checklist.

3. The Administrative Reviewer may use DRGF.11 encompassing the scope listed below.

4. The Administrative review milestone in LIMS reflects the technical and administrative review of the case.

D. Administrative review will take place prior to the release of the report. Refer to the Division Manual for release of information verbally. See FSD.43.

1. The administrative reviewer will consider the following scope, which includes, but may not be limited to:

a. All information is correct on case report header (agency case number, name, agency, offense, request date, etc.)

b. The administrative and examination records are uniquely identified.

   i. The unique identifier is the laboratory number.

   ii. There is a clear identification of the end of the report.

c. Proper report format followed per Division policy

d. The signature (or electronic equivalent) of the author appears on the report

e. Clarity of conclusions in report

   i. the reference to the sample selection plan is in the report annex

   ii. the date of sample selection is typically the date of analysis, this will be included in the case notes

   iii. clarity of how many units were tested in multiple unit cases or how many pills were examined in items with multiple pills, the results relate only to items tested
iv. uncertainty of drug weights, will be included in the report annex
f. Method(s) used or analytical techniques employed listed on report
g. The description and identification of submitted items is clear
h. The tape-sealed condition of the outer packaging is noted
i. Chain of custody documented in report and LIMS. The date of request is included on the report. The date of receipt of evidence is in the report annex.
j. Evidence items listed on request form correspond to reported items
k. The notes are legible
l. Correct grammar and spelling
m. All handwritten corrections to notes shown by initialed single strike-out
n. All handwritten notes in ink
o. All notes pages, including data, are properly marked with lab number, date and initials
p. The first and last notes page includes the total number of pages
q. Photos (pill identification printout) have description of what is being depicted
r. Disposition of the evidence is given in the notes if the evidence is not being returned to the submitting agency
s. Any communication is documented in the notes or telephone log documents

END OF DOCUMENT
I. **Policy:** Managers/Supervisors or persons designated by the Manager will review the testimony of their staff annually according to the following procedure.

A. Court Critique Forms ([FSDF.02](#) and [FSDF.03](#)) are available to staff members to encourage input from judges, attorneys, or peers regarding employee performance for courtroom testimony. The cards can be used in lieu of supervisory review of testimony.

B. There are other means of review of testimony that include, but may not be limited to, reviewing transcripts, or interview of an individual who witnessed the testimony. Refer also to the Division Manual policy on Courtroom Testimony Monitoring. See [FSD.17](#) and [FSD.26](#).

C. Individuals shall be given feedback regarding their courtroom monitoring. Typically, the analyst is provided a copy of the Court Critique. If a Court Critique is not filled out and returned to the analyst, the feedback shall be documented.

D. If performance is less than satisfactory, the Supervisor/Manager will gather appropriate information; this may take the form of interviewing the person filling out the Court Critique to determine the extent of the unsatisfactory performance.

   1. The Supervisor/Manager will address the performance with the analyst if they also deem the performance is unsatisfactory.
   2. Any remedial action taken will be documented; this may take the form of a corrective action if deemed necessary.

E. The records of testimony monitoring shall be retained not less than one full ASCLD/LAB International accreditation cycle. See [FSD.44](#).

F. If an individual does not testify in the calendar year, the Supervisor/Manager will document this according to the Division Manual policy. See [FSD.26](#).

II. **Policy:** Proficiency samples will be submitted to each analyst who performs testing, or an activity which contributes to the quality of testing, on a yearly basis.

A. These samples will be supplied by an outside agency, internally, or blind.
1. See QA.10 and DRG.57 for more information on using case samples or re-using samples for proficiency testing.

B. Proficiency samples may include controlled or non-controlled substances in solid or liquid dosage forms.

C. When participating in proficiency testing, the Controlled Substance Unit's own approved and documented test procedures shall be used

D. Criteria for passing drug analysis proficiency:
   1. For drug analysis proficiencies, all controlled substances must be identified. Appropriate presumptive and confirmatory testing will be documented in same manner as casework analysis. See DRG.43
   2. If a drug identification is missed or incorrect drug identification is made, then remedial training will occur and it will be documented in a QA Action.

E. See Division Manual policy FSD.23 for more information about complying with ASCLD/LAB Proficiency Review Program

F. The laboratory shall maintain records of proficiency testing, including:
   1. The test set identifier
   2. How samples were obtained or created
   3. Identity of the person taking the test
   4. Date of analysis and completion
   5. All data and notes supporting the conclusions
   6. Proficiency test results
   7. Discrepancies noted (refer to the Division Manual Policy FSD.23 and FSD.15)
   8. Indication that performance has been reviewed and feedback to the analyst
   9. Details of any corrective action taken (refer to the Division Manual Policy FSD.15)

G. Records shall be retained not less than one full ASCLD/LAB International accreditation cycle. See FSD.44.

END OF DOCUMENT
I. Policy: New procedures or methods of analysis must be validated or verified before use in casework.

A. Any new method or procedure or adjustment to a current procedure must be tested in our laboratory to insure that the method or procedure works, the verification or validation shall be as extensive as necessary to meet the needs of identification of a controlled substance. The laboratory shall record the results and document the procedure. Approval of the method for use in casework is documentation that the method is fit for the intended use. See FSD.27.

B. A Quality Action Request, or equivalent, should be generated and given to the Manager/Supervisor to be approved; then forwarded to the Quality Assurance Coordinator.

C. See the Division Manual policy for more information on validation: FSD.15, QA.18 and FSD.12.

D. Selection of Methods

1. The Controlled Substance Unit shall use test methods for identification of controlled substances, including methods for sampling which meet the needs of the customer and which are appropriate for the tests it undertakes.

2. When the customer does not specify the method to be used, the Controlled Substance Unit shall select appropriate methods. In general, the objective and scope of analysis is the identification of controlled substances.

3. Laboratory-developed methods or methods adopted by the laboratory will be used if they are appropriate for the intended use (identification of controlled substances). They will be validated to the extent necessary to meet the needs of the given application.
4. The customer shall be informed as to the method chosen by the Controlled Substance Unit listing the analytical techniques on the report.

E. The following factors shall be taken into account in developing test methods and procedures

1. **human factors**
2. **accommodation and environmental conditions**
3. **test and calibration methods and method validation**
4. **equipment**
5. **measurement traceability**
6. **sampling**
7. **the handling of test and calibration items**

F. *SWGDRUG Recommendations, Quality Assurance/Validation of Analytical Methods* may be used as an additional guide for validation of methods.

G. Documentation is required. A written description of the method used, instrument parameters, reproducibility data, and any other data should be documented and available for review.

H. Guidelines for Performance Verification

1. The purpose of performance verification is to ensure that a previously validated method, or method from a manufacturer, will work in our laboratory with our personnel and instrumentation.

2. Performance verification should consist of taking the validated method (without making significant changes to the extraction, GC/MS parameters, etc.) and demonstrating that the reference materials has been carried through the process and yielded the expected results. Prior to implementation of a validated method new to the laboratory, or a method from a manufacturer, the reliability of the procedure shall be documented in-house against any documented performance characteristics of that procedure. Records of performance verification shall be maintained.

3. The identification of a controlled substance is done with comparison to a reference material.

   a. If similar procedures (use of an internal standard, dilution of the sample with a solvent, and comparison to a reference material run using the same instrument parameters) are employed, then no verification or validation is required when new substances are encountered.

   b. Consideration to the appropriateness of solvent used and instrument run time should be considered when encountering new substances.

4. Qualified personnel criteria for a Performance Verification:

   a. For an instrument verification, an analyst who is competent in the unit can complete a performance verification.

   b. An analyst who is competency tested or in training can acquire data to be evaluated for the performance verification.
c. For new technology (such as instrumentation), an analyst who is competent in the unit can complete a performance verification.

I. Guidelines for Method Validation

1. The purpose of method validation is to demonstrate that the method is suitable for the intended use and is reproducible by our laboratory's personnel with the use of our instrumentation.

2. Method validation is required on new methods, methodology or procedures. Validation is the confirmation that the requirements for a specific intended use are fulfilled by examination of objective evidence.

3. Methods developed by the laboratory for its own use will be a planned activity and assigned to qualified personnel. Plans will be updated as development proceeds and effective communication between the analyst and Supervisor/Manager will be ensured.

4. Qualified personnel criteria for a Method Validation:
   a. For a method validation, an analyst who is competent and currently proficient in the unit can plan and coordinate a method validation.
   b. An analyst who is competency tested or in training can acquire data to be evaluated by a competent analyst for a method validation.
   c. For new technology (such as instrumentation), an analyst who is competent and currently proficient in the unit can plan and coordinate a method validation.

J. Software

1. When computers or automated equipment are used for the acquisition, processing, recording, reporting, storage or retrieval of test data, the laboratory shall ensure that laboratory configured software is suitably validated and documented as being adequate for use. In the Controlled Substance Unit, this may include, but is not limited to: a) Lab-created macros used for data analysis.

2. Commercial off-the-shelf software used within its designed application range will be considered to be sufficiently validated. In the Controlled Substance Unit, this may include, but is not limited to:
   a. Agilent ChemStation software and firmware
   b. the libraries used for presumptive identifications
   c. Reference software for the presumptive identification of pharmaceuticals (eg. AmerChem RX-ID) are considered approved
      i. Any version of AmerChem RX-ID
      ii. NIH/NLM website for pill identification: https://pillbox.nlm.nih.gov/
      iii. Poison Control website for pill identification: https://pill-id.webpoisoncontrol.org/
      iv. Drugs.com Pill Identifier: https://www.drugs.com/imprints.php
   d. JusticeTrax Indexer
e. Perkin Elmer FTIR software and firmware

3. Documentation of software validation will be reviewed by a Supervisor/Manager prior to approval for use. If the software is controlled or approved through the use of a software log, the approval initials in the log will document the review and approval of the validation. If the software is controlled or approved through PowerDMS, the electronic approval signature will document the review and approval of the validation. See FSD.34.

4. Records shall be maintained of software significant to the result and shall, when possible, be uniquely identified. This will be tracked on DRGF.12.

K. Equipment

1. Equipment that is new to the laboratory shall be properly evaluated to ensure its reliability. The evaluation will be as extensive as necessary to meet the needs of the controlled substance unit.

2. Before being placed into service, equipment shall be calibrated or checked to establish that it meets the laboratory’s specification requirements. It shall be checked or calibrated before use in casework.

3. If the type of equipment already exists within the laboratory and additional equipment of the same type is obtained, a check of the equipment may be satisfactory to ensure its reliability. This check shall ensure that the equipment is operating properly. This will be evaluated by the Supervisor/Manager.

4. If the equipment is a new methodology or the operation is significantly different from equipment already in the laboratory, validation, training and an associated competency may be necessary. This will be evaluated by the Supervisor/Manager. The competency test will meet the requirements in the ANAB.

5. See DRG.17 for information on equipment.

END OF DOCUMENT
I. **Policy:** Analysts or outside service technicians perform calibration checks and maintenance of equipment and instruments.

A. The Controlled Substance Unit is furnished with the measurement (balances) and test equipment (GC/MS, FTIR and microscopes) required for the correct performance of tests.

B. The equipment listed below and software used for testing is capable of achieving the accuracy required for weighing and qualitative testing of suspected controlled substances.

C. Equipment will be operate by authorized personnel. See DRG.43, DRG.44, DRG.45, DRG.46, DRG.47, DRG.48, DRG.49, DRG.50, DRG.51, DRG.52, DRG.53, DRG.54, DRG.55, DRG.56

D. Before being placed into service (to perform casework), equipment will be calibrated or checked to establish that it meets the laboratory's requirements. All balances will be calibrated before being used in casework. The test equipment shall meet the vendor's performance check criteria or the laboratory criteria before being used in casework. The check criteria will be documented.
1. See DRG.18 for the calibration program for balances.

E. After being placed into service, equipment will be calibrated or performance checked to establish that it continues to meet the laboratory's requirements. If equipment does not pass a performance check criteria or calibration tolerances (eg. AS FOUND data listed on the calibration certificate), an evaluation of the equipment's impact on casework will be completed and documented.

1. When an evaluation determines that the reported results are not affected, a level 2 log entry will be cross referenced in the equipment calibration log.

2. When an evaluation determines the reported results are affected, the impact will be documented through the QA ACTION process. See FSD.15

F. Each piece of equipment and its software significant to the test result in the controlled substance unit is uniquely identified. See DRG.32.

G. GC/MS

1. Each GC/MS in the Controlled Substance Unit is uniquely identified. Each of these has an accompanying maintenance binder that includes:

   a. The identity of the equipment (Laboratory assigned identifier) and software (version number or equivalent)

   b. The manufacturer's name and serial number or other unique identification

   c. The checks that the equipment complies with specifications (Autotune and Performance Standard Checks)

   d. The dates, results or reports of any adjustments. The report of the Autotune and Performance Standard Checks indicate acceptance criteria for use in casework

   e. Any damage, malfunction or repair

   f. Documentation of maintenance carried out

2. The instructions for use of GC/MS and the maintenance plan are contained in the Controlled Substance Unit manual.

   a. See DRG.19 - GC/MS Routine Maintenance

   b. See DRG.20 - GC/MS Cleaning the Ion Source

   c. See DRG.21 - GC/MS - Changing the Column

   d. See DRG.22 - GC/MS Cleaning the Inlet

   e. See DRG.23 - GC/MS Vacuum Pump Maintenance

   f. See DRG.24 - GC/MS Cleaning the Liners

   g. See DRG.25 - GC/MS Using the Software

   h. See DRG.26 - Storage of Instrumental Data

   i. See DRG.27 - GC/MS References

H. FTIR
1. The FTIR in the Controlled Substance Unit, is uniquely identified. It has an accompanying maintenance binder that includes:
   a. The identity of the equipment (Laboratory assigned identifier=FTIR) and software (version number or equivalent)
   b. The manufacturer's name and serial number or other unique identification
   c. The checks that the equipment complies with specifications (ready checks)
   d. The dates, results and copies of reports or certificates of maintenance or adjustments
   e. Any damage, malfunction or repair
   f. Documentation of maintenance carried out

2. The instructions for use of FTIR and the maintenance plan are contained in the Controlled Substance Unit manual.
   a. See DRG.28 - FTIR Analytical Procedures
   b. See DRG.29 - FTIR Spectrometer Sample Prep and Cleanup
   c. See DRG.30 - FTIR Spectrometer Maintenance
   d. See DRG.31 - Fourier Transform Infrared Spectrometer References

I. Microscope
   1. The Microscopes in the Controlled Substance Unit are uniquely identified. Each of them have a maintenance binder that includes:
      a. The identity of the equipment
      b. The manufacturer's name and serial number or other unique identification
      c. The annual external maintenance checks that the equipment complies with specifications
      d. The instructions for use are located in the Training sections of the Controlled Substance Unit manual, this is not listed in each maintenance log.
      e. The dates, results and copies of reports or certificates of maintenance or adjustments
      f. Any damage, malfunction or repair
      g. The documentation of the maintenance is in the maintenance log.

J. Balances
   1. The balances in the Controlled Substance Unit are uniquely identified. Each balance has a maintenance binder that includes:
      a. The identity of the equipment
      b. The manufacturer's name and serial number or other unique identification
      c. The Monthly Calibration checks that the equipment complies with specifications
d. The dates, results and copies of reports or certificates of calibrations or any adjustments.

e. Any damage, malfunction or repair

f. Documentation of maintenance carried out

2. The instruction for use of balance and the maintenance plan are located in the Controlled Substance Unit manual.

a. See DRG.18

K. Equipment that needs repair shall be taken out of service. It shall be clearly marked or labeled as being out of service until it has been repaired and/or shown by calibration or test to perform correctly. If there is a concern that the defect affected previous tests, the laboratory shall investigate.

L. See DRG.18 for information on calibration, intermediate checks and the calibration program for balance check weights

M. Test equipment will be handled according to procedures in the SOP and in accordance with training such that the equipment is safeguarded from adjustments which would invalidate the test and/or calibration results. If any damage, malfunction or repair is needed the equipment will not be used for casework until remedial action is taken.

1. Procedures for proper use of the GC/MS, FTIR and balances can be found in the associated GC/MS, FTIR and Balances procedures. Procedures for the proper use of the microscope can be found in the Training sections. By following the procedures and using equipment in accordance with proper training equipment will be handled in such a way to safeguard the equipment from adjustments that may invalidate test results.

N. Accommodations and Environmental Conditions

1. The laboratory is in a climate controlled building and the lighting and energy sources are suitable for drug analysis.

2. There are no environmental conditions in the technical requirements for testing drugs that need to be documented or monitored.

3. If power to any equipment is lost, analysts will ensure that equipment is properly working prior to resuming drug analysis.

4. Reference materials that require refrigeration are stored refrigerated and the refrigerators are monitored. See TOX.17 for further information on monitoring.

5. There is physical separation between drug unit and toxicology units, where cross contamination may occur. To further prevent cross contamination, analysts from either unit remove lab coats before entering the other section.

6. Access to areas of the laboratory are limited and controlled. See also Drug Unit Security (DRG.02) and Division Policy (FSD.32).

7. Analysts are responsible for maintaining a clean work area and general lab cleanliness. Trash is picked up from the lab and routine cleaning is performed by General Services Department (GSD). Non-routine cleaning (e.g., floor waxing, etc.) is scheduled with General Services Department (GSD). See FSD.50.
I. Policy: Balances will be calibrated and checked to ensure their reliability.

A. New or Serviced Balances
   1. A balance new to the laboratory, or a balance that has been serviced or has undergone substantial maintenance will be calibrated by an ISO 17025 compliant vendor before being used in casework.

B. Annual Calibration
   1. The balances in the drug unit will be calibrated yearly by an external calibration service that is ANAB ISO 17025 compliant. The certificates obtained will contain the measurement results including the measurement uncertainty and/or statement of compliance with an identified metrological specification. See FSD.28 and FSD.30.
      a. The unit will report correction factors to the UOM committee for evaluation.
   2. The laboratory will maintain copies of the certificates obtained for at least the current five year accreditation cycle.
   3. The external calibration service labels each balance to indicate the calibration status, including the last calibration and the recommendation for the next calibration.

C. Monthly Accuracy or Calibration Check
   1. The balances in the Drug Unit will be checked monthly to ensure that they are operating satisfactorily. This procedure shall be performed by an analyst or a specialist.
   2. Calibration or accuracy checks must be done with reference standards that are NIST (National Institute of Standards and Technology) traceable or American Society for Testing and Materials (ASTM) - ASTM 1 or ASTM 2 weights.
   3. The results of the check will be logged. During the monthly check, the balance should also be checked for cleanliness and to ensure that it is level. See DRGF.02.
   4. Procedure for checking the calibration of the balances in the Drug, Alcohol and Toxicology Section.
      a. Turn the balance on
b. Ensure that the balance is level

c. Tare the balance to a zero weight (0.000)

d. Place the weight (M1) on the center of the balance. (See Table 1 for the reference standard M1 as appropriate for each balance).

e. Record the weight result in the Balance Calibration Log

f. Remove the reference standard (M1)

g. Tare the balance to a zero weight (0.000)

h. Repeat with the reference standard M2. (See Table 1 for the reference standard M2 as appropriate for each balance).

i. Record the weight result in the Balance Calibration Log

j. Remove the weight (M2)

5. Refer to Table 1 for the allowable error range

6. If the balance falls outside the acceptable range the balance must be taken out of service. Calibration may be performed by an external calibration service meeting the requirements of ANAB ISO/IEC 17025.

7. The following references were used during the development of this procedure:

a. Instruction Manual for Precision Advance Electronic Balances, GT Series. Ohaus

D. Instructions for weighing on the balance.

1. Before an item is weighed, make sure:

   a. The balance does not have any issues with routine calibration and monthly checks.

   b. The balance should be placed in a stable location to minimize vibrations, air drafts, and unnecessary movements.

   c. If the balance indicates that it is not level, adjust the level appropriately.

2. Open the draft shield by the side-loading door.

   a. The top-loading door will only be used for sufficiently tall items.

3. Place the weighing media (vessel, weigh boat, weigh paper...etc.) near the center of the weighing pan.

   a. If a weigh boat is being used, the analyst will use the best weigh boat for the item being weighed to help increase visibility (contrast) and minimize spills (sturdier weigh boats for heavy items).

4. Tare the weighing media.

   a. Allow the weight displayed to stabilize before pressing TARE

5. Remove weighing media from balance and add item to be weighed.
a. Be mindful and use caution when transferring contents into and out of the weighing media

b. Always assume that an item is in the weigh boat to minimize the chance of a spill

c. For suspected fentanyl-related items, use proper Personal Protective Equipment (PPE) and only make content transfers while items are in the hood. See DRG.58 for more information.

6. **Place weighing media on scale, near center.**

   a. Do not place item(s) on edge of the weighing pan as this may cause inaccurate results

7. **Close the draft cover, if applicable.**

   a. The draft cover (sliding doors or lid) should be closed while taking a weight measurement.

8. **Weigh item.** Allow enough time for balance to settle. If the balance will not settle (more than 10 seconds and still fluctuates) use the lowest weight.

9. **Record the weight.** See DRG.42 for more information about reporting weights.

E. **Handling of Equipment:** Follow the instructions for using the equipment.

1. The balance should not be adjusted by laboratory staff as this may invalidate the calibration. If adjustments and calibrations are necessary, they are performed by an external calibration laboratory either on-site or off-site.

2. For off-site service, the balance will be transported to the external calibration laboratory in a secure packaging to prevent any damage.

3. The specifications for calibrations have been determined by the external calibration laboratory and meet the guidelines of euramet cg-18 and ASTME 898.

F. Reference Standards

1. The reference standards, check weights, will be checked yearly by an external calibration service that is ISO 17025 compliant. The certificates obtained will contain the measurement results including the measurement uncertainty and/or statement of compliance with an identified metrological specification. See FSD.28 and FSD.30.
   a. The unit will report correction factors to the UOM committee for evaluation.

2. The laboratory will maintain copies of the certificates obtained for not less than the current four year accreditation cycle.

3. All reference standards will be stored, handled, used and transported in a manner that prevents contamination, deterioration and protects the integrity of the reference standard. This includes:
   a. Storing reference standards in the packaging provided by the manufacturer to prevent deterioration.
   b. Handling reference standards, when practical, with the tweezers provided to minimize deterioration.
   c. Using reference standards for their intended purpose i.e. balance calibration checks.
      i. If a reference standard is dropped, it will be sent out for calibration.
   d. Transporting reference standards in the packaging provided by the manufacturer to prevent deterioration. Transporting reference standards may be necessary when weights are transported to/from the external calibration laboratory.

END OF DOCUMENT
I. Policy: The Gas Chromatograph/Mass Spectrometer (GC/MS) instruments will be checked to ensure their reliability. Maintenance will be carried out if needed according to the procedures below.

A. The following checks are performed as part of the Weekly Maintenance Checks. If the instrument is not in use and the checks cannot be done due to staffing levels, this will be logged in the maintenance log.

1. A Standard Spectra Auto Tune is performed weekly.
2. Standard Specta Auto Tune Interpretation:
   a. EM Volts should be reasonable depending on the age of the instrument and the electron multiplier (typically 1200-2400 Volts). A higher EM voltage may indicate a need for a source cleaning. The EM Volts should not exceed 3000.
   b. The EM Volts should not vary significantly from previous autotunes.

</tbody>
</table>

c. Peak widths (Pw50): 0.45-0.65 amu.

d. Ions with an amu of less than 69 should have an abundance less than 10% of the base ion (69 amu). If ions 18, 28, and 32 are higher than 10% this may be an indication of a leak.

e. Vacuum pressure and mass spectrum temperatures should not vary significantly from previous autotunes.

f. If the above criteria are not met, corrective action shall be taken.

g. The analyst performing or evaluating the autotune will initial the printout.
h. Printouts of the Autotune (Standard Tune) and the Performance Standard check will be kept in the Gas Chromatography/Mass Spectrometry Maintenance Binder. See DRG.17 for further information about the maintenance log.

3. Performance Standard Check
   a. Printouts of the Performance Standard Check will be kept in the Gas Chromatography/Mass Spectrometry Maintenance Binder.
   b. The Performance Standard consists of a mix of commonly encountered compounds covering a broad span of elution times. The mixture of compounds can be changed upon the Drug Units discretion to optimize retention time monitoring.
   c. The Performance Standard shall be run using the General (Gen.M) Method.
   d. The chromatography should not differ significantly from previous chromatograms of the Performance Standard.
   e. Relative retention times should not vary significantly from previous chromatograms of the Performance Standard (not greater than +/-5%).
   f. The analyst performing or evaluating the performance check will initial the printout.
   g. If the above criteria are not met, corrective action shall be taken.

4. Change Septum
   a. The inlet septum is changed weekly or more often as needed.
   b. The recommended septum is the Agilent Inlet Septa. These septa are preconditioned and it is recommended that they be handled with tweezers for best results.
   c. The injector port shall be visually inspected to ensure that the port is clean.

5. Change Insert (Liner)
   a. The insert (liner) is changed weekly or more often as needed.
   b. The insert will be replaced with a clean, silanized insert.
   c. A small amount of silanized glass wool is added to the insert.
   d. The new insert is accompanied with a new liner o-ring.
   e. See DRG.24 for procedure for cleaning dirty liners

6. Check Vacuum Pump Oil Level
   a. The oil level in the rotary pump should be checked if an oil rotary pump is installed. The level of oil should be at least half full. See DRG.23 for vacuum pump maintenance.

7. Documentation
   a. Changing the septum, insert (liner) and vacuum pump maintenance will be noted in the Gas Chromatography/Mass Spectrometry Maintenance Binder.
B. Quarterly-Moisture Traps

1. The moisture traps for each of the gas lines shall be checked quarterly. The check will be logged in the aide binder.

2. A change in the color of the indicator beads suggests the presence of moisture or oxygen and the trap/filter kit needs to be replaced.
   a. Moisture Trap (yellow originally, turns clear when saturated)
   b. Oxygen Filter (green originally, turns grey when saturated)
   c. The medical air line will have the oxygen filter saturated and can still be used

3. Procedure for changing moisture traps:
   a. Turn off the main gas line.
   b. Refer to manufacturer's instruction for replacing the trap/filter kit.
   c. REMEMBER: Changing the filters on the carrier gas line means that the oven, injector, and detector temperatures have to be at room temperature, unless the procedure is performed rapidly. If you do not do this, the column will be damaged.
   d. Changing the trap/filter will be logged in the aide binder

C. Non-Routine Maintenance

1. Agilent GC 6890 refilling the calibration vial
   a. The calibration vial is refilled with PFTBA as needed.
   b. This may be based on visual inspection of the calibration vial or if issues are observed during a tune.
   c. Ensure that the MS analyzer and any attached gauges are off. (The MS does not have to be turned off or vented but the MS must not be collecting data.)
      i. In the Tune and Vacuum Control view, select MS OFF from the Execute menu.
   d. Loosen the calibration vial collar by turning it counterclockwise - do not remove collar.
   e. Remove calibration vial and refill with PFTBA - leaving the top 6 mm of vial unfilled.
   f. Push vial all the way back into collar, then withdraw the vial 1mm.
   g. Tighten collar (turn clockwise). Hand tighten only - a tool should not be used to tighten the collar.
   h. From Tune and Vacuum Control, in the Vacuum menu, select Purge Cal Valve
      i. This must be done before any type of analysis is done
      ii. Refilling of the vial and subsequent purging of the valve will be documented in the maintenance binder.

2. Agilent Intuvo GC 9000 refilling the calibration vial
a. The calibration vial is refilled with PFTBA as needed.
b. This may be based on visual inspection of the calibration vial or if issues are observed during a tune.
c. Ensure that the MS analyzer and any attached gauges are off. (The MS does not have to be turned off or vented but the MS must not be collecting data.)
   i. In the Tune and Vacuum Control view, select MS OFF from the Execute menu.
d. Remove the analyzer window cover
e. Loosen the calibration vial collar. Do not remove the collar
f. Pull the calibration vial out. You may feel some resistance due to residual vacuum
g. Refill with PFTBA. With the vial vertical, the liquid should be just below the end of the internal tube, approximately 70ul of sample.
h. Push the calibration vial into the valve as far as possible
   i. Withdraw the vial 1mm. This prevents damage when you tighten the collar
   j. Tighten collar (turn clockwise). Hand tighten only - a tool should not be used to tighten the collar.
k. Reinstall the analyzer window cover
l. From the Tune and Vacuum Control, in the Vacuum menu, select Purge Cal Valve
m. **Refilling of the vial and subsequent purging of the valve will be documented in the maintenance binder.**

3. Agilent GC 6890 split vent maintenance
   a. Changing the split vent trap (may also be referred to as chemical trap)
      i. Split vent trap maintenance should be done whenever ion source or column maintenance is performed
      ii. Change the method to maint.m to cool the inlet and oven.
      iii. Stop the inlet gas flow.
      iv. Remove the top, rear cover on the GC. It is on by pressure-fit only, no screws need to be removed.
      v. Remove the weldment and gas lines from the holding bracket. Try not to stress or kink the gas lines.
      vi. Unscrew the big knurled knob of the vent line trap weldment.
      vii. Note the orientation of the old trap.
      viii. Remove the white trap and 2 o-rings. The o-rings may stick and can be removed with tweezers.
      ix. Place 2 new o-rings into the indentations onto the ends of the new trap.
x. Place the new trap into the trap weldment, narrow end toward the front of the GC. Screw the knurled knob until the vent line trap weldment is back together, but do not tighten yet.

xi. Place the weldment and gas lines back into the bracket.

xii. Tighten the knurled knob until sealed.

xiii. Replace the GC cover.

xiv. Reload a valid method and allow gases to purge the inlet for about 15 minutes.

b. Cleaning the split vent line

i. Split vent line maintenance is an option when troubleshooting GCMS issues

ii. Change the method to maint.m to cool the inlet and oven.

iii. Stop the inlet gas flow. The column may need to be capped to prevent air from entering the system. This may not be necessary if other maintenance is being done such as changing the column.

iv. Remove the top, rear cover on the GC. It is on by pressure-fit only; no screws need to be removed.

v. Move the tower.

vi. Unscrew the auto-sampler carrousel.

vii. Unscrew the top, left inlet access panel.

viii. Unscrew the top, left, back cooling-fan access panel if needed.

ix. Unscrew the nut connecting the split vent line to the inlet.

x. Unscrew the nut connecting the split vent line to the trap weldment.

xi. Carefully extract the vent line from the GC housing. Try not to stress or kink the vent line or other gas lines.

xii. Place the line vertically in a large beaker. Use the beaker to catch solvent wash waste. Dispose of organic chemical waste properly.

xiii. Wash the vent line with a variety of solvents until the washes run clear. Solvent suggestions include: methanol, acetone, chloroform, and methylene chloride. Use gravity to add each solvent at the trap weldment end, washing debris out the inlet end.

xiv. Cotton swabs can be used to clean debris out of the vent line ends and the inlet port.

xv. Allow the vent line to dry.

xvi. Thread the vent line back into the GC housing.
xvii. Reconnect the nuts at the inlet and trap weldment ends.

xviii. Replace the 3 GC covers, the carrousel, and the tower.

xix. Start the gas inlet flow.

xx. Slowly increase the inlet temperature over time, allowing any remaining solvents to evaporate and purge.

xxi. Allow gas to flow through the inlet at high temperature for about 15 minutes.

4. Agilent Intuvo GC 9000 split vent maintenance
   a. Changing the split vent trap (may also be referred to as chemical trap)
      i. Split vent trap maintenance should be done whenever ion source or column maintenance is performed
      ii. Prepare the inlet and GC for maintenance (there are three possible ways)
         1. From the GC touchscreen, navigate to Maintenance > Inlets > Perform Maintenance > Replace Split Vent Trap (check box) > Start Maintenance
            1. This option provides step-by-step instructions from the GC screen, which are summarized below
         2. From the GC touchscreen, navigate to Maintenance > Instrument > Perform Maintenance > Maintenance Standby Mode > Start Maintenance
         3. Change the method to maint.m or maint2.m to cool the inlet and oven.

      iii. Remove the split vent trap cover (top, back of GC)
      iv. Loosen the black knurled knob that secures the filter cartridge in place
      v. Gently pull forward the split vent trap assembly
      vi. Remove the old filter cartridge and insert a new one. The cartridge should only fit one way. Remove any o-rings that may have been left behind from the old trap
      vii. Gently push the assembly back into place and tighten the knurled knob finger tight
      viii. Check for leaks
      ix. Reinstall the split vent trap cover
   b. Cleaning the split vent line
      i. Split vent line maintenance is an option when troubleshooting GCMS issues. Due to the long coiled transfer line, replacement may be a better option than cleaning
      ii. Prepare the inlet and GC for maintenance (there are two possible ways)
1. Change the method to maint.m to cool the inlet and oven.

2. From the GC touchscreen navigate to Maintenance > Instrument > Perform Maintenance > Maintenance Standby Mode > Start Maintenance

   iii. Move the tower and remove the GC inlet cover

   iv. Remove the split vent trap cover

   v. Stop the gas flow

   vi. Unscrew the nuts of the transfer line from the inlet to the split vent trap assembly

   vii. Place or hold the line vertically over a large beaker to catch solvent wash waste. Dispose of organic chemical waste properly.

   viii. Wash the vent line with a variety of solvents until the washes run clear. Solvent suggestions include: methanol, acetone, chloroform, and methylene chloride.

      1. Note that the line is coiled and pressure from a wash bottle may help

   ix. Cotton swabs can be used to clean debris out of the vent line ends and the inlet port.

   x. Allow the vent line to dry.

   xi. Thread the vent line back into the GC housing and reconnect the nuts to the inlet and split vent trap assembly

   xii. Return the covers and tower

   xiii. Start the gas inlet flow.

   xiv. Slowly increase the inlet temperature over time, allowing any remaining solvents to evaporate and purge.

   xv. Allow gas to flow through the inlet at high temperature for about 15 minutes.

5. For non-routine maintenance on procedure for cleaning the ion source - Refer to DRG.20.

6. For non-routine maintenance on procedure for changing the column - Refer to DRG.21.

7. For non-routine maintenance on procedure for cleaning the inlet - Refer to DRG.22.

8. For non-routine maintenance like ordering parts, see DRG.27. These references may be used for troubleshooting and maintenance procedures.

9. Any additional maintenance will be noted in the Gas Chromatography/Mass Spectrometry Maintenance Binder.

   a. This includes but is not limited to

      i. vacuum pump maintenance such as changing the tip seal on a scroll pump
ii. replacing the Weldment Assembly

iii. switching the tower or autosampler, even if on a temporary basis

END OF DOCUMENT
I. Policy: Procedures for cleaning the ion source.

A. Ion Source Cleaning
   1. There isn't a recommended interval for ion source cleaning. The following changes in the tune are indications that the ion source needs cleaning:
      a. Inadequate abundances at high masses
      b. Low overall sensitivity
      c. Missing isotopes
      d. Incorrect isotope abundances
   2. For additional information, refer to the HELP menu on any version of the instrument software and look for "Testing for a dirty ion source"

B. Cleaning the Ion Source on Agilent 5973
   1. On the computer, from Instrument Control, go to the pull-down menu and select View-Tune and Vacuum Control
      a. Chemstation: From the Vacuum menu select vent, then click OK. This takes about 40 minutes
   2. Chemstation software may be shutdown at this point. Some versions of software will automatically shutdown once venting is complete.
   3. Set up the workstation with butcher paper, beakers, microgrit, GC instrument bag, sand paper, etc.
   4. Turn the front inlet down to 40°C
   5. After the vent cycle has completed, turn the Mass Spec off via the power switch
   6. Remove the cover of the mass spec
   7. Open the vent valve (turn to the left), the hissing should not last more than one minute. After venting, close the valve.
   8. Loosen the side plate thumbscrew if necessary.
      a. The front and rear side plate thumbscrews should remain unfastened during instrument use
      b. The rear plate thumbscrew should be tighten for only shipping purposes
   9. Disconnect the side board control cable and the source power cable
   10. Open the mass spectrometer
   11. Put the lint free gloves on at this point
   12. The quadrupole wires (top set of green beaded wires and white wires) do not need to be disconnected from the feedthrough board. Disconnect the ion source wires from the feedthrough board (bottom set of green beaded wires and white wires)
   13. Disconnect all the wire connections from the ion source
   14. Remove the thumbscrews that connect the source heater assembly to the source radiator
   15. Gently slide the source out of the source radiator
16. Close the door, slightly tighten the plate thumbscrews to keep the door closed during source cleaning
17. Take the source over to a clean area (with tools, butcher paper, green sandpaper, and lint free cloth.
18. Set the source on top of the source rest, on top of the lint free cloth
19. Using a Hex wrench unscrew the screws on the top of the source starting with the screws on the filaments. Pull out the filaments with the tweezers and set the filaments and screws aside.
20. Take the nut & the washer off the top and set aside
21. Take the repeller out and take the white ceramic loop off.
22. Set the plastic pieces off to the side with the screws and ceramic part
23. The plastic pieces may be cleaned with a cotton tipped applicator dipped in methanol. Do not touch the plastic pieces with your hands after cleaning them. The ceramic part is too fragile to clean.
24. Only the metal parts require cleaning:
   a. 
   | Agilent 5973 |
   | repeller |
   | interface socket |
   | source body |
   | drawout lens |
   | drawout cylinder |
   | ion focus lens |
   | entrance lens |
   b. The metal repeller block insert is not directly in the sample path, but may be cleaned if needed.
   c. The repeller block insert might not be present on the Agilent 5973
25. Sand all the surfaces, inside and outside, of all the metal pieces until they are shiny and there are no longer any black marks. Try to use a figure eight pattern when possible to reduce scratching. To sand the inside of some pieces, wrap the sandpaper around the metal rod and sand the inside surface.
26. Mix approximately two scoops of microgrit with methanol to achieve a slurry-like consistency
27. Use cotton tipped applicators to clean any remaining black surfaces. Rinse the microgit off into a waste beaker before putting the pieces in a 250 ml beaker with DI water.
28. Sonicate the metal parts using one of the following schemes:
   a. Traditional
      i. One time in DI water for 15 minutes
      ii. Two times in Methylene Chloride for 15 minutes each (organic waste)
      iii. One time in Acetone for 15 minutes
      iv. One time in Methanol for 15 minutes
   b. Non-chlorinated solvent option
      i. Two times in DI water for 15 minutes each
      ii. One time in Methanol for 15 minutes
      iii. One time in Acetone for 15 minutes
      iv. One time in Hexane for 15 minutes
29. When transporting the parts from one bath to another, use the tweezers to grab the "non-shiny" surfaces when possible. When sonicating be sure to fill the water level up so it ½ to ¾ up the side of the beaker.
30. After the final sonication put metal pieces in a clean dry beaker to dry. They can be allowed to dry overnight at room temperature in a ventilated hood or dried more quickly in an oven. To dry in oven, cover beaker loosely with aluminum foil and place in the oven at 100 degrees for approximately 15 minutes
31. Put on the lint free gloves and assemble the source:
a. Assemble the lens stack:
   i. Slide the draw out plate (disk) and draw out cylinder into the source body (ensure the windows of
      the draw out cylinder align with the windows on the source body).
   ii. Reassemble the entrance lens and ion focus lens inside the plastic lens insulator.
   iii. Slide the lens assembly into the source body.

b. Slide the lens stack into the source body, ensure the prongs on the side are lined up in the center.

c. Tighten the set screw into the source body to hold everything together, check that the windows are still
   lined up on the cylinder and source body.

d. Set the assembly on the source rest.

e. Screw in interface socket.

f. Place the ceramic piece onto the bottom of the repeller. The repeller is placed through the heater block
   assembly and another ceramic piece is placed on top of the repeller. Install a washer, if applicable, and
   tighten with repeller nut.

g. Put the heater block assembly on the source body and tighten the washer and nut. The wires of the repeller
   assembly are on the same side of the source body as the prongs that stick out.

h. Tighten the screws on the top of the assembly.

i. Put the filaments on (the one on top is #1). The shield should face out and the filament should face the
   source.

j. Tighten the filament screws.

32. Slide the source into the source radiator, tighten the thumbscrews (2) until they are finger tight.

33. Reconnect the wires from/to the feedthrough board:
   a. Blue wire to entrance lens.
   b. Orange wire to ion focus lens.
   c. White wires to filament 1 (top).
   d. Red wire to repeller.
   e. Black wires to filament 2 (bottom).
   f. Ion source heater wires (green).
   g. Ion source sensor wires (white).

34. Close the analyzer chamber door.

35. Reconnect the side board control cable and the source power cable.

36. Ensure the vent valve is closed.

37. Apply pressure to the MS door by pushing on it.

38. Turn on the MS. Maintain pressure while the instrument initiates and pumps down.
   a. Pump down can be initiated/completed with or without the instrument software being loaded.
   b. Pump Down is typically initiated once the MS is turned on. However, it can also be initiated from the MS
      front panel (Menu: Maintenance, Item: Pump Down).
   c. If the instrument software is loaded, it can be initiated from the Vacuum menu: Pump Down.

39. The turbo speed should rise, or for the diffusion pump it will begin the cycle. Completion of the pump down can
    be seen on the instrument front panel or the instrument software. Once pump down is complete, the MS
    temperatures must be returned to operating conditions: when asked about temperatures click APPLY (MS
    Zones) and OK. From Instrument Control, load a method other than Maint.M, such as Bakeout.M or Gen.M.

C. Agilent 5973 diagrams
D. Cleaning the Ion Source on Agilent 5977

1. On the computer, from Instrument Control, go to the pull-down menu and select View-Tune and Vacuum Control
   a. MassHunter: From the Vacuum menu select MS Vacuum Control, click on the vent button

2. MassHunter software may be shutdown once venting is complete.

3. Set up the workstation with butcher paper, beakers, microgrit, GC instrument bag, sand paper, etc.
4. Turn the front inlet down to 40°C
5. After the vent cycle has completed, turn the Mass Spec off via the power switch
6. Remove the front cover and side cover of the mass spec
7. Open the vent valve (turn to the left), the hissing should not last more than one minute. After venting, close the valve.
8. Loosen the side plate thumbscrew if necessary.
   a. The front and rear side plate thumbscrews should remain unfastened during instrument use
   b. The rear plate thumbscrew should should be tighten for only shipping purposes
9. Disconnect the side board control cable and the source power cable
10. Open the mass spectrometer
11. Put the lint free gloves on at this point
12. The quadrupole wires (top set of green beaded wires and white wires) do not need to be disconnected from the feedthrough board. Disconnect the ion source wires from the feedthrough board (bottom set of green beaded wires and white wires)
13. Disconnect all the wire connections from the ion source
14. Remove the thumbscrews that connect the source heater assembly to the source radiator
15. Gently slide the source out of the source radiator
16. Close the door, slightly tighten the plate thumbscrews to keep the door closed during source cleaning
17. Take the source over to a clean area (with tools, butcher paper, green sandpaper, and lint free cloth.
18. Set the source on top of the source rest, on top of the lint free cloth
19. Using a Hex wrench unscrew the screws on the top of the source starting with the screws on the filaments. Pull out the filaments with the tweezers and set the filaments and screws aside. Washers may be present with these screws; the washers do not need to be cleaned
20. Take the nut & the washer off the top and set aside
21. Take the repeller out and take the white ceramic loop off.
22. Set the plastic pieces off to the side with the screws and ceramic part
23. The plastic pieces may be cleaned with a cotton tipped applicator dipped in methanol. Do not touch the plastic pieces with your hands after cleaning them. The ceramic part is too fragile to clean.
24. Only the metal parts require cleaning:
   a. 
   | Agilent 5977 |
   | repeller |
   | repeller block insert |
   | source body |
   | extractor lens |
   | ion focus lens |
   | entrance lens |
   b. The extractor insulator is not cleaned
25. Sand all the surfaces, inside and outside, of all the metal pieces until they are shiny and there are no longer any black marks. Try to use a figure eight pattern when possible to reduce scratching. To sand the inside of some pieces, wrap the sandpaper around the metal rod and sand the inside surface.
26. Mix approximately two scoops of microgrit with methanol to achieve a slurry-like consistency
27. Use cotton tipped applicators to clean any remaining black surfaces. Rinse the microgrit off into a waste beaker before putting the pieces in a 250 ml beaker with DI water.
28. Sonicate the metal parts using one of the following schemes:
a. Traditional
   i. One time in DI water for 15 minutes
   ii. Two times in Methylene Chloride for 15 minutes each (organic waste)
   iii. One time in Acetone for 15 minutes
   iv. One time in Methanol for 15 minutes
b. Non-chlorinated solvent option
   i. Two times in DI water for 15 minutes each
   ii. One time in Methanol for 15 minutes
   iii. One time in Acetone for 15 minutes
   iv. One time in Hexane for 15 minutes

29. When transporting the parts from one bath to another, use the tweezers to grab the "non-shiny" surfaces when possible. When sonicating be sure to fill the water level up so it ½ to ¾ up the side of the beaker.

30. After the final sonication put metal pieces in a clean dry beaker to dry. They can be allowed to dry overnight at room temperature in a ventilated hood or dried more quickly in an oven. To dry in oven, cover beaker loosely with aluminum foil and place in the oven at 100 degrees for approximately 15 minutes.

31. Put on the lint free gloves and assemble the source:
   a. Assemble the lens stack:
      i. Insert the extractor insulator and the extractor lens into source body (ensure the windows of the draw out cylinder align with the windows on the source body).
      ii. Reassemble the entrance lens and ion focus lens inside the plastic lens insulator.
      iii. Slide the lens assembly into the source body.
   b. Slide the lens stack into the source body, ensure the prongs on the side are lined up in the center
   c. Tighten the set screw into the source body to hold everything together, check that the windows are still lined up on the cylinder and source body
   d. Set the assembly on the source rest
   e. Place the ceramic piece onto the bottom of the repeller. Then place the repeller block insert over the ceramic insulator. Insert this assembly through the heater block assembly and place another ceramic piece on the repeller. Insert washers and tighten with repeller nut.
   f. Put the heater block assembly on the source body and tighten the washer and nut. The wires of the repeller assembly are on the same side of the source body as the prongs that stick out
   g. Tighten the screws on the top of the assembly
   h. Put the filaments on (the one on top is #1). The shield should face out and the filament should face the source
      i. Tighten the filament screws

32. Slide the source into the source radiator, tighten the thumbscrews (2) until they are finger tight

33. Reconnect the wires from/to the feedboard:
   a. Blue wire to entrance lens
   b. Orange wire to ion focus lens
   c. White wires to filament 1 (top)
   d. Red wire to repeller
   e. Black wires to filament 2 (bottom)
   f. Ion source heater wires (green)
   g. Ion source sensor wires (white)
   h. Extractor lens wire (brown)
34. Close the analyzer chamber door
   a. There will be slight resistance to the closing of the door as the interface tip seal fits into the source body. Be sure the parts are aligned and do not try to force if strong resistance is felt.

35. Reconnect the side board control cable and the source power cable
36. Ensure the vent valve is closed
37. Turn on the MS. Maintain pressure while the instrument initiates and pumps down.
   a. Pump down can be initiated/completed with or without the instrument software being loaded
   b. Pump Down is typically initiated once the MS is turned on. However, it can also be initiated from the MS front panel (Menu: Maintenance, Item: Pump Down).
   c. If the instrument software is loaded, it can be initiated from the Vacuum menu: Pump Down
   d. Gentle pressure may need to be applied to the MS door during pump down
38. The turbo speed should rise, or for the diffusion pump it will begin the cycle. Completion of the pump down can be seen on the instrument front panel or the instrument software. Once pump down is complete, the MS temperatures must be returned to operating conditions: when asked about temperatures click APPLY (MS Zones) and OK. From Instrument Control, load a method other than Maint.M, such as Bakeout.M or Gen.M

I. Policy: Procedures for changing the column, cutting the column, and other column maintenance

A. Changing the Column on Agilent 6890

1. Injector end
   a. When changing the column, best practice is to vent the MS and allow to cool
   b. Turn the inlet and oven temperature to room temperature
   c. Unscrew the nut from the inlet, remove the column, the nut may be save and re-used with a new ferrule
   d. Remove the insulator cup under the injector port by removing the screws
   e. Remove the Reducing nut with a 1/2 inch wrench to access and replace the goldseal
   f. Discard the old goldseal and washer
   g. Before inserting the new goldseal, sonicate it in methylene chloride for 15 minutes
   h. Put in the washer, then the gold seal. The flush part of the gold seal should be facing up so it comes in contact with the liner. Attach the Reducing nut and insulator cup
      i. The liner rests of the flush part of the gold seal
   i. If a guard column is used, the guard end should be marked. The guard end of the column goes into the inlet
   j. Unwind a little of the column
   k. Cut a septum into quarters and insert a piece of septum onto the column as a guide
   l. Thread the column through the septum; then thread a column nut and injector ferrule through the column
      i. the flat, wider end of the ferrule goes against the column nut
   m. Cut 10 cm off the column and check the cut with a magnifying glass, it should be smooth and no jagged
   n. Wipe off the column with a methanol
   o. Adjust the septum up the column until there is 4-6 mm of column sticking out of the end of the ferrule/nut
   p. Install the nut to the inlet end
   q. Turn on the gas flow and inspect the detector end of the column. Place the end of the column in a vial of methanol and check for bubbles to ensure there is gas flow and pressure throughout the column
   r. Make sure the pressure is on before conditioning the column. Set the pressure to at least 12 PSI.
   s. Oven parameters for conditioning can be directly inputted from the GC interface
i. Time-30 min
ii. Temp-30
iii. Rate-10
iv. Final Temp-280 (or 5-10 degrees above the highest temperature method)
v. At least 120 minutes (up to 8hrs - 480 min)
vi. Enter, then hit START

t. The serial number of the column should be logged in the maintenance log. Any manufacturer's verification paperwork for the column should be filed in the maintenance log.

2. Detector end
   a. If necessary remove the existing column and disconnect the nut on the detector end with a wrench; slide the column completely out of the transfer line. The nut may be saved and re-used with a new ferrule
      i. If the nut appears worn or if there's swelling, it should be changed
   b. Cut a rubber septa into quarters, insert a piece of septum onto the new column to use as a guide
   c. Insert the nut and then ferrule; the pointed end of the ferrule rests against the inside of the nut
   d. Wipe the column down with methanol
   e. Cut approximately 3-8cm (1-3iches), check that the cut is straight and not jagged
   f. Wipe the column down with methanol
   g. Insert the column into the detector transfer line; move the septum and nut up to the thread and turn the nut slightly onto the thread
   h. Start backing up the column until approximately 1mm is sticking out of the MS transfer line
      i. The column installation tool can be used to assist in proper measurement of the column
   i. Tighten the nut and again check for the proper distance of 1mm. Finish tightening the nut and the nut may make noise to indicate a tight fit
   j. Close the doors to the oven and MS and pump down

B. Clipping the Column on Agilent 6890
   1. As sections of the column become contaminated, they can be removed.
      a. Typically 1 or 2 loops from the inlet side will need to be removed to bring the column to acceptable performance.
      b. One loop is approximately 50 centimeters
   2. The procedures for changing the column above can also be used to "clip" or cut the column which can extend the life of the column without replacing the column
   3. The MS can be left on and does not need to be vented, as long as maintenance is done at a sufficient pace without interruptions. The oven and inlet are cooled so that the inlet column assembly can be taken apart.
   4. The desired amount is cut from column and then the column is reinstalled into the inlet.
   5. Fill out an entry in the maintenance log

C. Agilent 6890 Diagrams
D. Changing the column on Agilent Intuvo 9000
   1. Prepare the GC for maintenance (there are two possible ways); the GC does not need to be turned off
      a. From the GC touchscreen, navigate to Maintenance > Columns > Perform Maintenance > Install Column > Start Maintenance
i. This option provides step-by-step instructions from the GC screen, which are summarized below
b. Load maint2.m to cool all part of the oven
   i. It is important to use maint2.m and not maint.m is used to ensure all parts (guard chip, column, inlet chip, detector chip, and transfer line) in the GC are cooled properly

2. Open the GC front door and lower oven door; remove the bus door
3. Remove the two compression bolts at the top of column assembly, these will be reused
4. Open the column clamps (4 total), unplug the smart key, and remove the column
5. Using forceps for the entire process, remove the old gasket and replace with a new gasket
6. Install the new column, carefully to holding it only by the outer ring
   a. Place column on the bottom clamps, tilt the column up to fit into place
   b. Loosely install compression bolts
7. Ensure column is correctly placed and aligned with the gasket; tighten compression bolts until one click on the torque wrench
8. Close the column clamps, insert the smart key
   a. The software should automatically recognize the type and length of column installed
9. Reinstall the bus door and close the lower oven door and GC door

E. Replacing the Guard Chip on Agilent Intuvo 9000
1. Prepare the GC for maintenance (there are two possible ways); the GC does not need to be turned off
   a. From the GC touchscreen, navigate to Maintenance > Inlets > Perform Maintenance > Replace Guard Chip > Start Maintenance
      i. This option provides step-by-step instructions from the GC screen, which are summarized below
   b. Load maint2.m to cool all part of the oven
      i. It is important to use maint2.m and not maint.m is used to ensure all parts (guard chip, column, inlet chip, detector chip, and transfer line) in the GC are cooled properly
2. Remove the ALS injector and inlet cover
3. Open the GC front door and remove the bus door
4. Slide the guard chip cover to expose the guard chip compression bolt
5. Loosen the sealing screw at the base of the inlet (7/16-inch open-end wrench)
6. Loosen the guard chip compression bolt with a torque wrench; the bolt is accessed from above where the inlet cover would rest
7. Depress the front of the guard chip heater assembly to expose the guard chip
8. Lift the right side of the guard chip and pull out of the GC.
9. Remove the left side of the guard chip from inlet base.
10. Install the new guard chip - the large end inserts into the inlet base and the smaller end inserts into the GC flow path.
    a. Place the large end into the inlet base
    b. Rotate the right end into the fitting
    c. Finger tighten compression bolt until you feel slight contact on the guard chip
    d. Raise the guard chip heater assembly and finger tighten the inlet sealing screw
e. Ensure the guard chip is seated correctly and tighten sealing screw and compression bolt.

11. Tighten the sealing screw

12. Tighten the compression bolt with the torque wrench until you hear one clock

13. Reinstall the bus door, inlet cover, and ALS; close the GC door

F. Flow path maintenance on Agilent Intuvo 9000 - Flow path maintenance is not performed often but is similar to installing a GC column. General directions are listed below

1. See Intuvo maintenance manual (G4580-90004) for directions
   a. Replace Inlet Chip
   b. Replace Detector Chip
   c. Replace MS transfer line

2. Prepare the GC for maintenance (there are three possible ways); the GC does not need to be turned off
   a. From the GC touchscreen, navigate to Maintenance > Inlets > Perform Maintenance > Replace Guard Chip > Start Maintenance
      i. A general work scheme is summarized below
   b. From the GC touchscreen navigate to Maintenance > Instrument > Perform Maintenance > Maintenance Standby Mode > Start Maintenance
   c. Load maint2.m to cool all part of the oven
      i. It is important to use maint2.m and not maint.m is used to ensure all parts (guard chip, column, inlet chip, detector chip, and transfer line) in the GC are cooled properly

3. Remove the ALS and inlet cover; open the GC front door and lower oven door, remove the bus door

4. For the Inlet Chip, the Guard Chip must be removed and the compression bolt loose. Both must be changed if changing the Inlet Chip

5. For the MS transfer line The MS must also be vented

6. Open latches that secure the chip and/or loosen any compression bolts

7. Remove the chip and unplug the smart key; remove any gaskets if applicable

8. Install the chip into it's proper fitting with a new gasket if applicable

9. Close and latches or tighten and screws

10. Plug in smart key

11. Reinstall the bus door, ALS, and inlet cover

12. Close the GC lower door and front door

G. Agilent Intuvo 9000 diagrams
Figure 4 shows the Intuvo major bus components.
I. Policy: The following procedures will be used for cleaning the inlet. Cleaning the inlet used to be a common practice but Agilent Technologies does not currently recommend this practice as regular maintenance if liner insert and split vent trap changes are performed regularly. Inlet cleaning should be one of the last options when troubleshooting GC/MS issues.

A. The following is the procedure from the Agilent Technologies for the GC 6890.
Split/Splitless Inlet Cleaning Procedure
5890 and 6890 Split/Splitless Inlets

The Split/Splitless inlet will become active (degrading certain types of compounds) over time. In some cases, just changing the liner and the gold seal will not remedy this problem. In these cases a more vigorous cleaning procedure must be implemented. The following procedure has been developed to help in this process.

The following parts and solvents will be needed:
- 38-caliber brass gun barrel cleaning brush with metal rod.
- Methylene Chloride
- Acetone
- Methanol
- Glass transfer pipettes with bulb
- “Kimwipes”
- Safety Glasses
- Lab Coat
- Nitrile Chemical Resistant Gloves

1. Cool the inlet. This is best accomplished by reducing the inlet temperature to 40C. Leaving the inlet on allows the injection port fan to continue to operate thus, aiding in cooling the injection port. It is also helpful to lower the oven temperature to 40C. These steps can be performed from the GC front panel or the Chemstation software.
2. After the inlet has cooled sufficiently (at least 70°C), turn the inlet flow off.

3. If an autosampler is in place, remove tower, tray and top cover.

4. While wearing appropriate safety apparel, remove the weldment assembly that covers the GC liner. Remove the liner completely from the GC. Notice a flow line that sits below the weldment, this is the split vent flow line. This should have a 7/16” swagelok fitting, loosen the fitting and remove the split vent flow line.

5. Turn the GC oven off and open the door. Loosen and remove the GC column nut from the inlet. Place a septa over the injection port end of the column, so as NOT introduce O2 to the column. Remove the insulator and the gray reducing nut that houses the gold seal and washer from the bottom of the inlet.

6. The injection port consists now of just a long metal tube. All flow lines and the glass liner have been removed from the assembly. Dip the gun brush into the Methylene chloride and insert the brush into the inlet completely. MOVE THE BRUSH UP AND DOWN DO NOT TWIST. Perform this step twice. Then use the glass pipette to rinse the inlet with Methylene Chloride. Follow the Methylene Chloride rinse with an Acetone brush and rinse and finish with a Methanol brush and rinse.

7. After the last Methanol brush and rinse, dab the top of the inlet with a “kimwipe” to remove any residual solvent that may pool. Look down through the assembly to make sure that it is free of particles that may stick to the walls of the inlet. Heat the inlet to 65°C to flash vaporize the solvent away. (THIS IS A CRITICAL STEP THAT CANNOT BE BYPASSED).

8. Reassemble the inlet with a new gold seal, washer, liner, and a new ferrule on the column. Make sure that the column is re-cut prior to installation. Reinstall the split vent line and tighten. Reinstall the weldment assembly (NOTE: Prior to reinstalling the autosampler assembly turn the injection port flow back on. Do not turn the injection port temperature on.) Check to make sure that proper head pressure can be obtained, if not recheck all fittings for leaks.

Before increasing the temperature, let the inlet sit at 65°C for about 10 minutes to remove any oxygen that might be in the inlet. THIS STEP MUST NOT BE SKIPPED. IF IT IS THE CLEAN PARTS JUST INSTALLED WILL BE REOXIDIZED.
9. After 10 minutes heat the inlet to operating conditions. Let it stabilize for 5 minutes. Make at least 2 blanks runs before any analyte is injected, to make sure that the inlet has been successfully cleaned. Be aware this technique does not work on all applications, and over time will not bring the inlet back. The assembly will need to be changed in time.

Please make sure that there is full understanding of this procedure prior to disassembly of injection port. If you are unable to complete this procedure please Call Agilent.

B. Agilent Intuvo GC 9000 cleaning the inlet
   1. Prepare the inlet and GC for maintenance (there are two possible ways)
      1. From the GC touchscreen navigate to Maintenance > Instrument > Perform Maintenance > Maintenance Standby Mode > Start Maintenance
      2. Change the method to maint2.m to cool the inlet and oven.
   2. Turn off the GC
   3. Remove the tower and inlet cover
   4. Remove the liner and guard chip
   5. Due to the compression nut and the small space in the oven, a gun brush will not be used. With a clean cotton swab, dip the swab in methylene chloride to clean the inlet. Check that there are no cotton fibers in the inlet.
6. With a clean swab, repeat with acetone
7. With a clean swab, repeat with methanol
8. Repeat as necessary until the inlet is clean
9. Flash the inlet at 65°C for 10 min
10. Install a new liner insert and guard chip
11. Continue with maintenance or prepare the system for a Standard Spectra Tune.

END OF DOCUMENT
I. Policy: The following is the procedure for vacuum pump.

A. General Information
   1. There are two types of GC/MS vacuum pumps that may be found in the Controlled Substance Unit
      a. Oil rotary pumps
      b. Dry scroll pumps

B. Dry Scroll Pump Maintenance
   1. The basic maintenance for a dry scroll pump consists of changing the tip seal and the exhaust silencer filter. The tip seal should be changed approximately every 9000 hours or when there is an increase in pump base pressure. If an exhaust silencer is installed on a dry scroll pump, the filter should be changed when the tip seal is changed.
      a. Changing the tip seal
         i. Vent the Mass Spec. See the instructions in DRG.20 (GC/MS-Cleaning the Ion Source) for proper venting.
         ii. Make sure the Mass Spec power is OFF
         iii. Turn off pump and remove electrical cord
         iv. Carefully remove the exhaust silencer if it is attached
         v. Remove the Front Cowling and Outboard Housing by removing their respective bolts
         vi. Change the Tip Seal
            1. replace the o-ring
         vii. Attach Front Cowling and Outboard Housing
         viii. Attach the exhaust silencer
         ix. Plug in electrical cord and turn on pump
         x. Pump down MS
         xi. Make an entry in the maintenance log
         xii. Exterior surfaces may be cleaned with isopropyl alcohol
b. Changing the exhaust silencer filter
   i. Remove the front cover of the exhaust silencer
   ii. Replace filter
   iii. Attach exhaust silencer cover

C. **Oil Rotary Pump Maintenance**

1. If possible, the pump oil should be changed in conjunction with a source cleaning when the instrument is already vented
   a. Vent the Mass Spec. See the instructions in DRG.20 (GC/MS-Cleaning the Ion Source) for proper venting.
   b. Make sure the Mass Spec power is OFF
   c. Place a container under the oil drain plug (drain valve) on the pump to catch the oil
   d. Open the oil filler located on the top of the pump
   e. Open the oil drain plug on the bottom of the pump and let the oil drain out
   f. Pour a small amount of clean oil through the oil filler to ensure all the dirty oil has been drained out
   g. Replace the oil drain plug
   h. Fill the oil filler with clean oil SLOWLY while viewing the oil sight glass
   i. Fill to at least ½ full in the oil sight glass, but do not fill completely (the oil level should remain visible in the window)
   j. Close the oil filler
k. Make an entry in the maintenance log
l. Once the pump is working again, check the oil level to ensure it is at least ½ full.

D. References

I. Policy: The following is the procedure for cleaning the GC liners. *(ISO/IEC 17025:2005 5.5.3)*

A. The criminalists should remove the glass wool from the liners and place them in a storage location away from clean liners.

B. Liners for controlled substances and toxicology can be cleaned at the same time.

C. **SAFETY**: Label all your glassware and put chemicals away when you are finished with them. Use Nitrile gloves, and clean the liners under a hood.

1. Soak the liners in chromic or nitric acid (**cleaning solution**) for one hour
   a. The cleaning solution is an acid. It is located in the acid cabinet in the Controlled Substance Unit
   b. Use a pasteur pipette to thoroughly wash the liners with the cleaning solution and attempt to submerge all the liners in the solution
   c. Recycle the cleaning solution acid after use (by pouring back into the bottle)

2. Rinse with **distilled water** (4-5 times with a pasteur pipette or squirt bottle). The waste should be collected into a beaker or equivalent and the water and acid waste should be disposed of in the acid waste.
   a. The liners should be placed onto paper towels (or equivalent) in between rinses to dry.

3. Rinse with **methanol** (4-5 times with a pasteur pipette or squirt bottle). The methanol waste should be disposed of in the organic waste.

4. Rinse with **hexane** (4-5 times with a pasteur pipette or squirt bottle). The hexane waste should be disposed of in the organic waste.

5. Soak the liners in **siloxane** or silane for 30 minutes (attempt to submerge all the liners)
   a. Cover the siloxane or silane with parafilm (or equivalent) or it will evaporate.
   b. Recycle the siloxane or silane after use (by pouring back into the bottle)
      i. The Siloxane Solution is 10% by volume Dichlorodimethylsilane in Pentane.
For example: 50 milliliters of Dichlorodimethylsilane would be added to 450 milliliters of Pentane in order to make 500 milliliters of a 10% Siloxane Solution

ii. The bottle should be labeled with hazard information (NFPA, or equivalent):

Blue 3, Red 4 and Yellow 3.

6. Rinse with toluene (4-5 times with a pasteur pipette or squirt bottle). The toluene waste should be disposed of in the organic waste.

7. Rinse with methanol (4-5 times with a pasteur pipette or squirt bottle). The methanol waste should be disposed of in the organic waste.

8. Rinse with hexane (4-5 times with a pasteur pipette or squirt bottle). The hexane waste should be disposed of in the organic waste.

9. Air dry completely (overnight) under the hood on a paper towel.

10. **Handle the liners with kim-wipes (or equivalent). Do NOT handle the clean liners with bare hands or gloves.**

11. Put the liners into their protective plastic sleeves (or equivalent) and return to the appropriate section.

END OF DOCUMENT
I. Policy: The following is the procedure for using the ChemStation and MassHunter programs available Drug Unit instruments

A. Instructions do not account for discrepancies between software versions but all software has a similar user interface.

1. Instructions were created from Instrument #12 which uses MSD ChemStation ver. E.02.00.493, however some screen images are from Instrument #7.

2. Instructions are intended to be used as a guide. Slight variations may exits for file paths, table names, access to certain applications, etc.

3. MassHunter Acquisition is used and has a similar interface and layout as ChemStation and was designed to appear similar.

4. ChemStation will be used for data analysis. MassHunter Data Analysis software is **not used** in the Drug Unit.

B. Folder Structure for data files and sequences

1. Create folders on the local drive for the storage of **(a.) Data** and **(b.) Sequence** information. Create folders through explorer as instructed below; some systems are configured with with different default paths and path location is not critical for the programs to function.

2. The default data location in ChemStation is C:\msdchem\1\DATA\xxxxxx

3. The Drug Unit's default location in MassHunter is D:\Data

4. The default sequence location in ChemStation is C:\msdchem\1\sequence\xxxxxx
5. The default sequence location in MassHunter is D:\MassHunter\GCMS\1\sequence

6. Open ChemStation or MassHunter application by double-clicking the instrument icon on the desktop. Wait for the system to initialize.

C. Creating a sequence - the name of a sequence is Sample Log Table in ChemStation and Sequence Table in MassHunter

1. Load any existing sequence as a template (analyst may make copy an existing sequence into their folder using Explorer). (Sequence > Load Sequence).
   a. Analyst may create a new sequence each time the instrument is used
   b. Alternatively, the same sequence can be changed for each use
   c. A sequence does not need to be saved for archive purposes

2. If edits to an existing sequence are made, the data file name and location must be checked so existing data is not inadvertently overwritten
3. Make changes to the sequence by selecting Edit Sequence from the menu bar (Sequence > Edit Sequence).
   a. The sequence table opens
   b. Make sure the Data Path is correct by checking the Data Path window. If it not correct, browse to the correct data path
   c. In the Method Data box, ensure the local method storage location is displayed.
   d. The default method location for ChemStation is C:\MSDCHEM\METHODS
   e. The default method location for MassHunter is D:\MassHunter\GCMS\METHODS
   f. Some systems are configured with with different default paths and path location is not critical for the software to function.
4. The sequence table typically contains the following fields however additional fields not listed may be selected or deselected for viewing in MassHunter. Ensure the fields are populated as instructed.

   a. **Type** - Click the drop down menu to select the appropriate sample type from the drop-down menu
   b. **Vial** - Indicate the location of the sample vial on the autosampler tray
   c. **Sample** - enter a sample description
      i. The description is typically blank, standard name, or the lab number and accompanying evidence information
      ii. MassHunter: this field is titled **Name**
   d. **Method/Keyword** - enter the method to be used for data acquisition and analysis
      i. It is recommended to select the Method from the menu instead of typing it manually
      ii. Keywords can be used for a variety of functions like setting timers for sequences and tunes, command line prompts, and changing the data path
         1. ChemStation
            1. The Data Path may be changed in the middle of a sequence by using the Method/Keyword field. In the Type field select Keyword, choose DataPath from the drop-down in Method/Keyword, and indicate the new Data Path in the Comment/Keyword String.
         2. MassHunter
            1. There is a separate field in the sequence table to change Data Path
            2. The **Keyword** field is separate from the **Method** field
   e. **Data File** - enter the name of the data file.
      i. The recommended format for a data file is YYMMDD## but is at the discretion of the analyst. Only the last two digit number at the end of the name should change when running samples in the same day.
      ii. For example, the first blank of the day can be named as YYMMDD01 and each proceeding sample will be an increment of the first blank
   f. **Comment/Keyword** - enter a description (typically the solvent used and the Internal Standard)
      i. MassHunter: The **Keyword** field is separate from the **Comment** field
   g. **Multiplier** - enter the correct multiplier as indicated by the analytical method, or enter 1.00000
      i. MassHunter: this field is named **Dil.** and may be deselected from viewing; it can be left blank if it is available in the sequence table
   h. **Level** - complete per analytical method requirements, if no instruction exists, leave blank
   i. **Update RF** - complete per analytical method requirements, if no instruction exists, select no update
   j. **Update RT** - complete per analytical method requirements, if no instruction exists, select no update
   k. **Update QI** - complete per analytical method requirements, if no instruction exists, select no update
1. **Update MZ** - complete per analytical method requirements, if no instruction exists, select no update

ChemStation Example:

2. **Saving the sequence and starting the sequence**
   
   1. **Saving the Sequence**
      
      a. Select Sequence > Save As
      
      b. Navigate to the correct folder location as created above
      
      c. Enter a sequence name
      
      d. The analyst may overwrite their own sequence
      
      e. Ensure the sequence is saved with the file extension (.s).
         
         i. MassHunter can use .s or .sequence.xml extensions
   
   2. **Starting the Sequence**
      
      a. Start the Sequence and check that the information in the Run Sequence screen is correct before beginning a run
      
      b. Run Sequence - to start from the beginning of the sequence (Sequence > Run Sequence)

      i. Analysts must use caution when the "Overwrite Existing Data Files" box is checked
c. Position and Run Sequence - to start from a certain place within the sequence (Sequence > Position and Run Sequence)
   i. The program will ask if the analyst wants to process the keywords before beginning the sequence and the analyst must select Yes if using keywords

![Sample Log Table for PERFS (on line 8 of 9)](image)

E. Data Analysis - All instruments use ChemStation data analysis software

1. Macros are a tool created for expediency; it is up to the analyst to ensure the correctness of the images that are created.
   For example:
   a. Mislabeling can occur if peaks are too close together.
   b. Mislabeling can occur if the standard file is annotated with one integration threshold (expecting a certain number of integrated peaks), but the sample is later annotated with a different integration threshold (resulting in a different number of integrated peaks).

2. Macro settings can be changed to correct labeling when improper labeling occurs.
   For example:
   a. "Change RT tolerance" will change how close a sample peak retention time must match the standard peak retention time to be automatically labeled.
   b. The integration threshold can be changed so that the standard file and sample file are annotated under the same threshold conditions.

3. If the macros are unable to produce correct labels, the analyst may have to manually annotate the peaks by other means.(See H. Manual Data Analysis)

F. Macros may be used to perform data analysis. (CCC Reports>Generic 3-Panel)

1. The data file for the sample is loaded first, the next data file loaded is the blank before the sample, and the last data file loaded is the properly annotated standard.
2. The analyst should evaluate criteria for acceptable chromatography such as peak resolution, peak shape, and retention times. The analyst must also evaluate criteria for acceptable mass spectra for confirmation.

3. The MS parameters may have to be changed to obtain optimal viewing and acceptable spectra. The scan within a peak can be changed as well as the X-axis or Y-axis range.

4. Background subtracted data is another useful macro (CCC Reports > Subtracted MS reports)
Find scan to subtract from the peak of interest

Start the macros

Follow the prompts which includes inputting the scan to subtract

G. Annotate Mode

1. The Total Ion Chromatogram (TIC) and Spectra (MS) for the files of interest may also be obtained in the Annotate Mode. The annotation mode allows for more alterations than the Generic 3-Panel macros. (CCC Reports>Annotate Mode)

2. Other functions in Annotate Mode include
   a. moving standard annotations so they are more visible
   b. editing peaks or placing an "x" over non-controlled stances or cutting-agents
   c. overlaying two chromatograms for samples with no common controlled substances

H. Manual Data Analysis

1. A Total Ion Chromatogram (TIC) and Spectra (MS) of the sample and standard used for identification can also be printed manually (without using the Macros).
   a. Load The data file of interest (TIC in window 2)
   b. Click on the peak of interest to obtain the spectra (SCAN in window 1)
   c. Label the TIC and SCAN appropriately
   d. Print the TIC & SPECTRUM

2. Comparison of spectra between a case sample and standard may be done manually (without using the Macros)
   a. Load the data file of interest and click or scan the desired peak
   b. Load the appropriate standard and click or scan the desired peak
   c. In the Command bar merge the two spectra, MERG
d. In the Command bar Normalize the two spectra, NORM

e. In the Command bar draw the two spectra in a window with the appropriate X and Y parameters, eg. DRAW 3,X,38:150:0:2000

f. Print the new window (eg. 3)

3. Chromatograms may be overlaid by using the Overlay Chromatograms tool (this is typically done for sample where no controlled substance is present and the sample is being shown with the blank immediately run before) (Tools> Overlay Chromatograms)

   a. Select the blank data file before the sample
   b. Integrate the Chromatograms (Chromatogram>Integrate)
   c. In the Command Bar draw the two chromatograms in the same window, eg. DRAW 3,R0

I. In general, data from the GC/MS is imaged into JusticeTrax using a program called JusticeTrax Indexer

   1. The person performing the data analysis and putting the images into JusticeTrax should be logged into JusticeTrax Indexer
2. The printer should be set to JusticeTrax Imaging
3. Type the laboratory number into the Locate field to search for requests associated with that laboratory number
4. Select the appropriate request and then enter the image number and item into the Enter Image Name field (e.g. IMG or DATA as a prefix)
5. Hit the Save button
6. See DRG.62 for additional information and printer settings.

END OF DOCUMENT
I. Policy: The following is the policy and procedure for storing electronic instrumental data.

A. GC/MS
   1. Electronic data files
      a. Analysts shall periodically back up all data files on a storage disk. Storage disks shall be maintained for a period of at least the current 5 year accreditation cycle.
         i. Data inclusive of casework, monthly standards and weekly maintenance checks are located in data folders on each computer.
   2. Methods
      a. All methods will be backed up on a storage disk. A copy will be kept at a location designated by the Manager/Supervisor.
         i. The GC/MS methods, inclusive of active and archived method settings are in the method folders on each computer.
      b. Minor changes may be made to methods without validation for methods that are run FULL SCAN and a standard is used for confirmation.
      c. A record of those changes will be tracked within the Method Comments screen.
      d. Examples of changes that can be made include, but are not limited to changing the solvent delay, split ratio, run time may be increased.
   3. Hardcopies of Data/Forms
      a. Printouts of all checks performed, shall be kept for at least the current 5 year accreditation cycle.
      b. Equipment Logs shall be kept for at least the current 5 year accreditation cycle.

B. FTIR
   1. Electronic data files
a. Analysts shall periodically back up all data files on a storage disk. Storage
disks shall be maintained for a period of at least the current 5 year
accreditation cycle.

i. The report spectra, inclusive of casework, monthly standards and
yearly checks are located in C:\pel_data\spectra

ii. The ready checks, inclusive of the weekly checks, reference spectra
and contamination checks run prior to casework are located in
C:\pel_data\Ready Checks

2. Methods

a. All methods will be backed up on a storage disk. A copy will be kept at a
location designated by the Manager/Supervisor.

i. The methods, inclusive of the UATR and Sample Holder method
settings are located in C:\pel_data\export

3. Hardcopies of Data/Forms

a. Printouts of all Checks performed, shall be kept for at least the current 5 year
accreditation cycle.

b. Equipment Logs shall be kept for at least the current 5 year accreditation
cycle.

END OF DOCUMENT
I. Policy: The following procedure will be followed for FTIR analysis.

A. The Universal ATR attachment or Sample Holder is used for FTIR sampling in the Controlled Substance Unit.

B. Before starting casework:

1. From the Spectrum software select Setup | Instrument. On the "Basic Instrument Setup" tab click the "Load and Save" button.

2. Select the line marked either:
   "Spectrum 100 UATR standard analysis settings"
   or
   "Spectrum 100 Sample holder standard analysis settings" depending on the analysis to be done. Press the "Set as Current" button.

3. This will load the default settings:
   a. Start: 4000
   b. End 500
   c. Resolution: 4
   d. Accumulations: 4
   e. Scan Type: Sample
   f. Abscissa Units: Wavenumber
   g. Ordinate Units: %T

4. If ready checks have not been performed with the specific sampling accessory, perform the ready checks according to DRG.30

C. For each sample analyzed using the UATR attachment do the following:

1. Make sure that the UATR attachment is connected to the FTIR. A toolbar icon will appear identifying the UATR.
2. Clean the crystal, top plate, and shoe on the pressure arm with methanol or similar solvent. Avoid using acetone. Make sure surfaces are dry before continuing.

3. Perform a Contamination Ready Check.
   a. From the Spectrum software select Measurement | Instrument Checks | Ready Checks | Contamination, or use the Contamination button.
   b. This report compares a spectrum of the clean attachment to the current state.
   c. Observed Absorbance values in all three ranges should be below 0.1000.
   d. If the Contamination Ready Check does not pass, further cleaning should be done.
   e. The Contamination Ready Check is automatically saved on the hard drive.
   f. The analyst will include the documentation from the PASSING Contamination Ready Check in the case notes.

4. Collect a background spectrum. Use the Background button.
   a. The analyst may record in the case notes that a background spectrum was taken.

5. Load the crystal.

6. Name the sample spectrum to be collected.
   a. Click on the "Sample Table" line in the Data Explorer pane.
   b. The "Save Location" field shows where the files will be saved. Click on the ellipsis (…) button to choose a new location.
   c. The SampleID field is a unique file name (i.e., the date plus a sequential number).
   d. The Description field should include the lab number, request number, evidence number identifier of the sample, and the initials of the analyst.
   e. NOTE: If the description field is changed after the sample spectrum has been collected, then the file will have to be manually saved to keep the changes.

7. Use the Monitor or Scan button to preview the spectrum and applied force. (The first press of the scan button enters preview mode, which is similar to monitor)

8. Use the pressure arm to push the sample against the crystal. The monitor screen will show the amount of applied force. Do not go above 150 N. Excessive force may damage the crystal. Liquids do not need the pressure arm.
9. Use the Scan button to collect a sample spectrum. (If using monitor, the first press of the Scan button may enter preview mode. Press the Scan button a second time to acquire the scan.)

10. The spectrum will be automatically saved in the designated location.

11. Clean the crystal, top plate, and shoe on the pressure arm with methanol or similar solvent.

D. For each sample analyzed using the sample holder do the following

1. Make sure that the slide holder attachment is connected to the FTIR. A toolbar icon will appear identifying the slide holder.

2. Since the slide holder does not have a sample crystal, the contamination check does NOT need to be done.

3. Collect a background spectrum. Use a setup that matches the intended sample method (i.e. an empty slide holder, empty pellet disk, or empty vapor cell). Use the Background button. The analyst will record in the case notes that a background spectrum was taken.

4. Load the slide holder:
   a. If a sample card is used, insert the card into the slide holder slots.
   b. If a KBr pellet or vapor cell is used, insert the V-channel into the slide holder slots and place the pellet disk or vapor cell in the channel.
   c. Name the sample spectrum to be collected.
      i. The "Save Location" field shows where the files will be saved. Click on the ellipsis (...) button to choose a new location.
      ii. The SampleID field is a unique file name (i.e., the date plus a sequential number).
      iii. The Description field should include the lab number, request number, evidence number identifier of the sample, and the initials of the analyst.
      iv. NOTE: If the description field is changed after the sample spectrum has been collected, then the file will have to be manually saved to keep the changes.
   d. Use the Scan button to collect a sample spectrum.
E. Identifications
   1. Confirmations
      a. See DRG.34
   2. Presumptive Library Identifications
      a. See DRG.34

F. Image Creation and Transfer
   1. In order to create readable data images in LIMS, the following settings are suggested:
      a. Set the JusticeTrax Imaging Printing Preferences:
         i. Set the Orientation to "Landscape"
         ii. Check the "Rotate Landscape image to Portrait"
      b. Set the Graph Properties in the Spectrum software:
         i. Make sure all the spectra in the window are selected.
         ii. Right click on a spectra name to bring up the option menu.
         iii. Select the "Appearance" menu option.
         iv. On the "Advanced" tab, set the Line Size to an appropriate thickness (typically 2-3)

G. References

END OF DOCUMENT
I. Policy: The sample preparations for FTIR analysis are given here as guidelines for casework.

A. FTIR UATR analysis
   1. Direct Analysis: a solid or liquid can be placed directly on the crystal.
   2. Alternatively, the sample can be extracted or cleaned before analysis. See examples below.

B. Vapor cell sample preparation
   1. Use the glass vapor cell cylinder located in the desiccator.
   2. There are two salt lenses (they are color coded blue and green) the green side should face left and the blue side should face right.
   3. Place a small filter paper so it will line the inside of the glass cylinder without blocking transmission through the side lenses.
   4. Put a drop of the substance onto the filter paper and seal the vapor cell by placing the lenses on each side.
   5. Allow time for the volatile substance to evaporate and fill the chamber.
   6. The vapor cell can be placed on the slide holder to analyze.

C. Cleaning vapor cell
   1. Put the salt lenses away in the desiccator.
   2. Rinse the glass cylinder with methanol and let dry, then put away in the desiccator.

D. KBr pellet sample preparation
   1. The ratio of sample to potassium bromide is approximately 1:2 (toothpick fulls).
   2. Mix the powder in a mortar and pestle until a very fine, homogeneous powder is obtained.
   3. Place the bottom disk anvil flat on the bench with the shorter or stubby shaft upward.
4. The die ring fits over the shaft forming a well to put the sample in.

5. Put the powder in the sample well in the disk. Put enough powder in to cover the entire bottom, but not so much that the disk will be too thick and occlude the IR transmission.

6. Place the top anvil disk on top of the ring, with the longer shaft downward. Twist the top on. The two shafts should meet in the middle of the die ring, compressing the powder.

7. Put the whole disk anvil in the “presser apparatus” and set to about 60.

8. Compress.

9. If necessary, open with a lever.

10. Carefully twist off the top and bottom anvil disks and view the compressed pellet inside the die ring. Take care when opening, so the pellet does not fly out. The pellet should look like a translucent film stretching across the hole in the die ring.

11. If the sample pellet is not acceptable for analysis then regrind and begin the preparation process again.

12. The middle die ring with the pellet can be placed into the slide holder for analysis.

E. **KBr pellet equipment cleaning**

   1. Poke out the pellet and dispose properly.

   2. Rinse the disks with water, then acetone and return to the desiccator.

F. **Film**

   1. Films can be placed directly into the slide holder.

G. **Standards and Libraries**

   1. FT-IR analysis using UATR, KBr (or other salt pellets), and polystyrene films will include the spectrum of the material used to make or hold the sample (diamond, KBr, and polystyrene).

      a. Libraries that match the sample preparation technique will create better matches.
b. Standards for confirmation should use the same preparation technique as the sample.

II. Sample Preparation Theory Overview: The extraction scheme in each sample cleanup procedure is determined by the solubility of the desired compound in each solvent being used to be able to extract either the impurities or retain the compound of interest. At the molecular level, solubility is controlled by the energy balance of intermolecular forces between solute-solute, solvent-solvent and solute-solvent molecules. Recall from general chemistry that intermolecular forces come in different strengths ranging from very weak induced dipole – induced dipole interactions to much stronger dipole-dipole forces (including the important special case, hydrogen bonding). However there is a simple, very useful and practical empirical rule that is quite reliable. That simple rule is “like dissolves like” and it is based on the polarity of the systems i.e. polar molecules dissolve in polar solvents (e.g. water, alcohols) and non-polar molecules in non-polar solvents (e.g. the hydrocarbon hexane). This is why ionic compounds like table salt (sodium chloride) or compounds like sugar, dissolve in water but do not dissolve to any great extent in most organic solvents. It also applies to the separation of oil and water (e.g. in salad dressings). The polarity of organic molecules is determined by the presence of polar bonds due to electro-negative atoms (e.g. N, O) in polar functional groups such as amines (-NH2) and alcohols (-OH). (reference: Forensic Chemistry, Suzanne Bell, 2nd Edition, 2013, pages 100-136). The solvents utilized in the extraction/cleanup methods below have been developed to take into account the solvents readily available in the laboratory which pose a minimal health risk when proper safety precautions are used.

A. Cocaine Salt Acetone Clean Up:
   1. Wash the sample with Acetone (Acetone is used as a solvent because of its high volatility and its ability to dissolve traces of petroleum solvents and water)
   2. Dry and analyze using FTIR-ATR.

B. Cocaine Salt Acetone Wash followed with CHCl3 extract:
   1. Take sufficient sample (~ 30-50 mg) into filter paper and wash with acetone (20-30 milliliters).
   2. Discard acetone.
   3. Let the filter paper dry and extract sample using chloroform into a collection watch glass or concentrator cup.
   4. Dry the collected chloroform. (Cocaine salt will be soluble in chloroform)
   5. Use a small amount of dried sample for FTIR-ATR analysis.

C. Cocaine Salt Cleanup-General:
   1. Place sample into filter paper
   2. Rinse with Diethyl Ether (removes Nicotinamide, Isonicotinamide, Benzocaine, Procaine base).
   3. Rinse generously with Ethyl Acetate (removes Caffeine).
   4. Dry the paper bearing the undisolved sample.
   5. Rinse with CHCl3 onto a watch glass or concentrator cup (removes Cocaine HCl from sugars and other insoluble material plus most of the Procaine HCl which is
only slightly soluble in CHCl₃.)

6. Evaporate to dryness.
7. Remove the excess crystals to a test tube.
8. Rinse the residue on the watch glass with hexane and allow to dry thoroughly.
9. Use the dried watch glass residue for the IR pellet or FTIR-ATR.

D. Cocaine Base Cleanup

1. Place 5 to 10 mg in a shell vial
2. Extract the sample with 0.2 to 0.5 ml hexane. (Cocaine Base will be soluble in hexane)
3. Move the hexane to a new vial.
4. If no further clean-up is needed, this hexane can be dried and used for IR analysis.
5. If needed, wash the hexane with 0.2 to 0.5 ml water.
6. If hexane liquid is used on the ATR crystal:
   a. Collect a background with a drop of blank hexane on the crystal.
   b. Place 1 to 2 drops of hexane with the extracted cocaine sample on the crystal and scan the sample spectra.
   c. If needed, evaporate the washed hexane to dryness. The resulting solid can be placed on the ATR crystal.

END OF DOCUMENT
I. Policy: The Fourier Transform Infrared spectrometer (FT-IR) will be checked to ensure its reliability. Maintenance will be carried out if needed according to the procedures below.

   A. Log into the Spectrum software as user "pe1". This login will have the proper settings and ranges for normal use and maintenance.

   B. The following Ready Checks are performed weekly when in use. If the instrument is not in use and the checks cannot be done due to staffing levels, this will be logged in the maintenance log. (ISO/IEC 17025:2005 5.5.3, 5.5.5 c, g):
      • Abscissa
      • Noise
      • Throughput

   1. The Ready Checks evaluate instrument performance with a sampling attachment in place. The Ready Checks with the UATR attachment are performed on a weekly basis. If other sampling attachments are intended to be used for casework, (such as the slide holder for vapor cell analysis), then the Ready Checks should be repeated prior to use in casework with those attachments in place.

   2. From the Spectrum software select Setup | Ready Checks.
      NOTE: There is a menu Setup | Instrument Verification that looks very similar to the Setup | Ready Checks, but they have different settings and purposes. Instrument Verification can be used to help trouble-shoot and diagnose problems with the instrument, and should not be used for weekly checks. Ready checks use the same scan parameters that regular samples use. These settings are found under the Setup | Instrument screens.

   3. The "Setup Ready Checks" tab shows which tests to run to ensure that "Abscissa", "Noise" and "Throughput" are checked. Leave the other tests unchecked.
4. The "Setup Throughput Check" tab shows the location of the reference spectrum as well as the parameters for the test.

![Setup Throughput Check Tab](image1)

5. The "Setup Contamination Check" tab shows the location of the reference spectrum as well as the parameters for the test.
